Second, the capacitor (.01 uF) which is shunting the 220k resistor in the first grid circuit of the CRT should be grounded at one side in such a manner that the wiper of the intensity pot will be at ground potential for ac. As it is now, the amount of flyback suppression is depending upon the position of the wiper, because in a lower position of that wiper, the flyback pulses are more or less ac grounded via both 8 uF capacitors in the power supply circuit.

For the benefit of the American hams, here are the equivalents for some items: EF91 = 6AM6; 800 piv/1 A = 1N4006 or 1N4007, eventually 1N521B or 1N5214; OA81 = 1N38, 1N98A, or 1N270; OA210 = 1N3194 or 1N4004.

Further, I'd like to give some hints. When using an old i-f transformer for the 455 kHz coil, do not short the second coil! This will lower the Q of the coil in use considerably, so remove it completely.

The two capacitors in series, via which the flyback suppression pulse is supplied to the first grid of the CRT, can better be replaced by one capacitor with a value of something like .01 uF, 1 kV. Two capacitors in series practically always have unequal charges, and if one becomes leaky due to overvoltage, the other will follow too. I found out too late and I ought to buy me a new CRT because the tube didn't like a positive grid voltage of around 400 volts.

Be aware of the very high potential difference between the filament and ground. Most filament transformers cannot withstand 800 volts. So better use a transformer with a very good isolation layer between primary and secondary windings. I did remove the original filament winding, put some extra layers of isolation material of PVC wrap over the primary, and rewound the secondary. The splattering was gone. It is very handy to add an i-f outlet on any receiver you have. To prevent loading or detuning the i-f transformers, a simple cathode, emitter, or source follower should be added to the receiver.

Anyway, the monitor scope is a very useful and cheap instrument and sure worth it to build!

CARF

Canadian Amateur Radio Federation, Inc.

The Canadian Amateur Radio Federation Inc. is pleased to announce the following awards available to all radio amateurs worldwide.

CANADAWARD: A colorful certificate will be issued to any amateur who confirms two-way QSOs with all Canadian Provinces and Territories. All QSOs to be on one band only. This certificate is endorsed as to band. Separate awards are issued for each band on which the applicant qualifies (12 cards per band).

A mode endorsement is available if all QSOs are made on the same mode (CW, SSB, RTTY, SSTV). Contacts made after July 1, 1977, only will count for this award. Submit the 12 cards with one dollar ($1.00) Canadian or U.S. funds or 10 IRCs plus sufficient funds for return postage. CARF members need send only funds for return postage.

5 Band CANADAWARD: A special plaque will be issued to any amateur who confirms two-way QSOs with all Canadian Provinces and Territories on each of five separate bands (total of 60 cards — 12 cards per band).

Contacts made after July 1, 1977, only will count for this award. Submit the 60 cards with seven dollars ($7.00) Canadian or U.S. funds or 70 IRCs plus sufficient funds for return postage. All CARF awards are free to CARF members. CARF members need send only funds for return postage.

6 Band CANADAWARD, 7 Band CANADAWARD, ETC.: Special endorsements to the basic 5 band CANADAWARD will be issued to any amateur who confirms two-way QSOs with all Canadian Provinces and Territories on more than 5 bands. Submit the additional cards with sufficient funds for return postage.

All amateur bands may be used. Each distinct satellite mode (432 in/144 out, 144 in/29 out, 144 in/432 out, etc.) will count as a separate band.

NOTE: These awards do not conflict with the WAVE and WACAN awards sponsored by the Nortown Amateur Radio Club.

Mail all applications for the CANADAWARDs to: P.O. Box 76752, Vancouver, B.C., Canada V5R 5S7.

Tracking the Hamburglar

RIPPED OFF: Clegg FM-DX 2 meter FM transceiver, s/n HM-298 and microphone were stolen from the van of WA3BGN on Feb. 5, 1977, in downtown Bridgeport CT. Anyone with information please contact Jon P. Zaimes WA3BGN, 681 Longhill Ave., Shelton CT 06484 (phone 203 929-4659) or the Bridgeport police department, file no. 6856.

LETTERS

AR73L?

Just a short letter to commend your fine effort in the area of amateur radio. In my opinion, *73* is the best magazine on the market. You always have up to the minute news on what's happening in our hobby. You also solicit people to write guest editorials if they disagree with you, and unlike other magazines, you even print them.

If there was one thing to be changed in *73*, it would be the computer I/O section. Though it is the up and coming trend in amateur radio, and although I have a great interest in the subject as a beginner, I feel the computer articles should be reserved for your new magazine, *Kilobaud*. I think there is nothing wrong with material about computers; I just believe construction and programming should be kept in the magazine that was designed for the specialist — *Kilobaud*. Computers just aren't everybody's bag of capacitors.

These are just my own personal feelings and I thought it might do some good to let you know where I stand. In all other areas, Wayne, just keep up the excellent work, and in the future we just may have the AR73L for the betterment of our hobby. Thanks for listening and for a super magazine.

Neil Kelly VE6CFI/W4
Temple Terrace FL

SPREAD THE WORD

I am in FULL accord with your opinions about Docket 20282 (and those numbers sound like the last mile). Did it ever occur to anyone (I know you caught it) that the individual who will apply for a freebie Communicator license — and pays his money — must *first* be interested in amateur radio? Therefore, and accordingly, someone MUST interest him! Without that interest nothing happens to the grand idea of the amateur cup running over. There is where the League has consistently dropped the hot potato — public relations. This little item requires pros and real ones. The Podunk Valley Radio Club cannot possibly get amateur radio into the media, but with all the affluence of the ARRL, it can do it — *if* it will set up the proper department and hire pros. Every other national organization I have heard of and joined spends money on just that! Nevertheless, the boys in the back room have hidden themselves in their Newington digs and repeatedly ask the young outsiders to spread the word. It cannot be done effectively in that manner. This I have written, discussed, and informed the Director and everyone I meet. I have received no solid reply except that it is a good idea.

If you interest the students, the Boy Scouts, the Girl Scouts, the Sunday schools, and even the stamp clubs, then and only then will there be a run for the licenses.

One minor comment: I have spoken before Ruritans, Kiwanis, Rotary, et al, and shown the much touted "Ham's Wide World." It's an interesting movie but *not* a movie to interest new hams. As I tried to tell some friends the other day: My shack is open any time you have someone you would like to exhibit ham radio to. However, if you show a youngster all the gear that has been accumulated in 35 years, you will immediately scare him away. He will either be so awed or so confused that he will immediately conceive the idea that the hobby is for the rich and the mighty. What really has to be done is to simulate the old 6L6 and oatmeal box and show them how it works.

Gay Milius, Jr.
Virginia Beach VA

LEARNING

This letter should really go to Peter Kendall WN3ZRG (Letters, Jan. issue, p.154), because it is for people like him that I am writing it. Pete, I completely disagree with your views, and actually take offense with your criticism of *73*. It seems as though you are *still* a neophyte to ham radio — not in the technical sense, but in the fraternal sense. You are selfish. Just because *you* have no interest in computers, you think they should not have a section in *73*. In thinking this way, you are depriving others that *do* have an interest in them the opportunity to learn more about them. If you ". . . see no need for (a computer) . . ." in your shack, fine — don't buy one. But there are others, with a little more upstairs than you or me, that *find* a need for one. I, too, don't need a computer in my shack (yet), but that doesn't mean I want to hack every I/O article in *73* to pieces with a meat cleaver. I'm a Tech and don't want a low band rig in my shack. I prefer VHF, but I don't want to sit in front of a fire and burn articles on keyers and CW filters. I want to read articles on the low bands — maybe I'll find some facet of operating that I'll be interested in. Enough of this self-glorification.

My point is that I don't think we should deprive others of something that they enjoy just as much as you enjoy the "distant station," or something I enjoy as much as bringing an old taxi radio to life on six meter FM. If terms like byte, ROM, RAM, etc., leave you in the dust, get up and try to learn them. If you don't want to, then lie there and be trampled by others who are not "conventional hams."

Please do write some articles on code speed, observations on the ham bands, etc. I'd enjoy reading them. Not because I care about operating at 40+ wpm, but for the same reason that I read the I/O articles — I want to learn.

Jim Heid WB3CWY
Pittsburgh PA

THE MENTAL BLOCK

Yesterday's arrival of *73* was a pleasant surprise, what with the mail tie-up during the holidays. As usual, it was interesting and informative. Read the Letters section; I used to agree with W5GOS about I/O articles. It took a tech talk by WA2PJS at the Dec ARATS (W2SEX — listen for us during FD '77) meeting to kindle a keen interest. By the way, took a digital course at college recently, found it easy and interesting, got a "B". Anyway, I/O is more interesting to me nowadays, but not enough to cause me to subscribe to a new magazine. I will, however, purchase the "Bugbooks" when time and finances warrant.

Having heard all the arguments for and against CW, I'd like to say that CW is just plain enjoyable operating. I like it. The *73* tape was a great assist in qualifying at 20 wpm at Rochester this spring. I'm an Extra now. Those who cry about the code probably have a mental block (they have programmed themselves *not* to learn it by thinking to themselves that it is impossible; I've been through *that* myself on occasion).

Whatever happened to SSTV? Editorials rambled on about it at length some time back, and now — nothing. Granted, there are many subjects to write about, and SSTV probably won't come up for some time again. Oh well.

Steered two CBers toward their ham tickets this summer and fall. One is an avid DXer; when he learned that several hundred mile QSOs are possible daily on the ham bands, he dug in and studied, attended an ARATS-sponsored ten week class. The other fellow always knew about ham radio, finally found the time and the help, and is nearly ready to try his code test. Met him in a barroom where he tried to pick my mind for antenna info. He's built several CB antennas so far, will grow into the HF ham bands soon. It's a good feeling, helping these guys. They'll still keep their CBs for utilitarian communications, though. The darn things *do* have a practical value.

Having recently passed my FCC Second Class Radiotelephone ticket and my Extra, and not having time for hamming, I'm still volunteering myself to help anyone in the Honeymoon Capital area toward obtaining a ticket.

Jeffry Blackmon WB2UYI

Niagara Falls NY 14304

BUS-MOBILE

Thank you for a most interesting issue, #195, Holiday, 1976.

Enclosed is a photo which I hope will be of interest to you, depicting as it does how readily one can adapt amateur radio to one's job given enough imagination! Working mainly night runs ("owls"), I found my Standard hand-held to be a welcome diversion during my layovers, as well as a convenient supplementary communications means in event of an emergency.

This photo was taken for a QSL card I am designing. Unfortunately, my having to be at the business end of a 1950 Exakta with a cantankerous self-timer precluded my being photographed in the bus with the Standard.

I would be most interested in hearing from other radio amateurs who may be similarly involved in the transportation industry.

In this area, "Locomotive Mobile" is also known!

Thank you for a very stimulating year one of my three year subcription. I read both *73* and *HR*, and find they complement each other nicely.

E. G. (Ernie) Kenward VE7BYK
North Vancouver BC

NAG MOBILE

I thought you might be interested in my system of mobile communication: Nag Mobile. In a world of machines, electronics, and computers, the west is still able to blend modern technology with the traditional western mode of travel — the horse. The Appaloosa pictured is able to differentiate between an antenna and a whip and is undisturbed by my mobile communication. There is no ignition noise or alternator whine — just an occasional whinny.

The transceiver, a Drake TR-22, is secured to the saddle horn, the coax is run under the saddle, and the antenna is a Larsen Mag (Nag) Mount secured to a metal strip which is affixed to the back of the saddle. In flat desert areas, the system is ideal, with no brush or trees to entangle the antenna — and it helps to have a cooperative horse. Long live the west!

Horse mobile is not unusual here in the west. The local repeater group helps with parades, and most trail rides utilize handie-talkies, but I have never seen a horse-mounted antenna. Hope you enjoy the photos.

Carol Sears WB7CUF
Phoenix AZ

P.S. My father, Stan Sears, (W2PQG) suggested your magazine, as it has a better reputation for printing articles than *QST* or other ham magazines.

Beats walking! — Ed.

see page 193

WARC

I read the writeup on the proposals for the WARC conference with considerable interest. I'm glad you went into detail on it in the February issue. I don't think the analysis went far enough, though; in the case of all but the HF bands, it didn't say much about the implications of the proposed changes, or the pros and cons. I hope there will be space in the future to educate us about bands we don't work, or haven't worked in the past. One question that comes to mind is: What's the purpose of satellite allocations in the HF bands?

Now, several comments. First, if it's argued that we need some spectrum space at in-between places to get reliable propagation when the present bands are out, for such jobs as handling the traffic arising out of the Nicaragua earthquake, maybe we don't need whole bands. As accurate as ham gear is getting, a few spot frequencies might be enough. Making them open only to traffic nets would keep them quiet most of the time, so high-priority traffic could get through, and letting the nets on would get them listened to periodically. Naturally, any ham should be able to declare an emergency and call. Next, I think it would be helpful all around if there were a few spot frequencies shared with other users. How about a common emergency frequency for hams, aircraft, inshore boats, and land mobile? FM on 144.000 MHz would be an obvious choice. Putting all the crash beacons on that frequency would free up 121.5 for urgent voice calling, as well as simplify WB6CQW's proposal for equipping 2m repeaters to detect ELTs. Now, a really radical suggestion, as wild as anything that ever came out of Peterborough. Has anyone considered the idea of trying to steer the EIA's grabby mitts away from 220 by suggesting that CB expand into 6 meters? Being right next door to channel 2, the TVI potential makes any significant amount of power a nearly hopeless proposition except for those who live far from cities. So 6 meter DX, while sometimes possible when propagation is right, is never going to be a workhorse. I've never heard more than half a dozen stations on the band, and none above 51 MHz. Meanwhile, as 2m fills up, the next logical place to put repeaters is 220, so we're likely to want it very soon. From the CBers' viewpoint, 6m would make a much better mobile band than 220, because the longer wavelength gets around obstructions better, and being closer to 11m, it would be easier and cheaper to make one transceiver cover both — probably as one continuous series of channels. By the same argument, ham gear could treat 2m and 220 almost as one band. Shared use of some low end channels on 6m could be a really cool idea, too. We could end up with a common emergency channel with direct input to police departments, and the chance to both demonstrate superior operating practices and rub noses in the benefits of such ham privileges as equipment modification and high power. Incidentally, I think any new CB channels should be sideband only, and not just to save spectrum. With all the benefits of having radio in everything that moves, carrier heterodynes make channel 19 pretty hard on the ears.

John A. Carroll K6HKB/1
Bedford MA

LONESOME SAILORS

I am a Coast Guard radioman, stationed onboard the *USCGC Ingham*. I have noticed that *73* has brought up some good suggestions for things to keep a sharp lookout for at the next ITU conference coming up shortly. Here is another one: the expansion of the use of present amateur bands in international waters, especially region 2.

There are a lot of things that us poor lonesome sailors miss out on, as far as I know, for no good reason at all. It would be great, for instance, if we could make use of the local area nets on 75 meters during the evenings, as a source of available operators for phone patches in our home port towns. 40 meters in the evening is too crowded with broadcast stations; even if the skip were short enough, that only leaves the 20 meter band, which gets expensive. (Do you suppose that could be the reason we can't use 75 meters? Hummm!)

In addition to this, it would be nice to be able to use all modes of OSCAR; presently we are restricted to inputs below 148 MHz.

Then there is that 1600 meter band the FCC has proposed. Experimentation from international waters on 1600m would be severely limited by the /mm limitation. The Navy has been using this band for a long time now for maritime (submarine mostly) workings, and I believe it would be a very dependable maritime amateur band.

Yes, there is a problem with LORAN on 160 meters, but with today's receiving gear, and a reasonable power limit (say 50 or 100 Watts), there is no reason to completely forbid working on that band either. Most of the other bands we are talking about are exclusively amateur, and would bother no one.

Enough criticism. I just want to say thanks for publishing the best, most open, and outright honest amateur magazine going, and I mean that from the heart. Keep up the good work; it is appreciated.

Mike Warner WA7LZQ/4
Portsmouth VA

ASCII

Radio hams have used teletype machines to communicate for many years, adapting the 32 character, 5 level machines that became readily available after World War II. Teletype communication was formally written into the FCC amateur regulations in 1953, specifying the 5 level Baudot code and standard speeds of 60 words per minute. Hams were not satisfied with the mechanical contraptions and paper tape storage, and with the advent of ASCII code, CRT terminals at low cost, and the 8-bit microprocessor, we look to modernize these ancient FCC regulations that encumber our development of the communications arts and sciences (if you want to use ASCII legally on the air, you can obtain a special temporary permit, but the process is slow and difficult). Hams have already established data transfer links between minicomputers in two different countries via the amateur radio satellite OSCAR 7, under special FCC permit using ASCII. Other computerized hams make regular schedules of cross-country data links by the kluge method of converting their ASCII computer output to Morse code, transmitting at more than 100 wpm, and converting back to ASCII at the other end.

Changes in radio regulations to reflect the current technology are long overdue, and a formal petition numbered RM-2771 has been entered requesting the allowance of ASCII 8 level code on the amateur bands. If the FCC hears support on this from the public, there will be a set of proposed rules made up and published for public comment. If comment is favorable, the rules could be changed in a year. Or the feds could just sit on ASCII forever if they don't hear from anybody. You can help by sending a simple comment (6 copies required by law) encouraging the FCC to act on RM-2771. Just take a note pad and a pencil and write six times: "I support RM-2771 allowing the use of ASCII code on the amateur radio frequencies." Add your name and address, and mail them to the Federal Communications Commission, Washington DC 20554. If you have access to a cheap copier, you may wish to elaborate on why ASCII radio transmission is desirable in your opinion, but a simple statement will do, as numbers seems to count more than eloquence at federal agencies. Be sure to mention RM-2771 by number.

J. R. Johnson WA5RON
Austin TX

SMOKEY

I read with interest your letter dated January 1, 1977. This letter, you may recall, was in response to a letter I wrote regarding the article "A Mobile Smokey Detector" in the Holiday issue.

As you pointed out, the United States of America celebrated a very glorious achievement last year. We celebrated the anniversary of a break

with a government that had, as Thomas Jefferson put it in the Declaration of Independence, "a long train of abuses and usurpations," one of these usurpations being "the abolishing of the free system of English laws."

Americans in 1776 were justified in doing what they did because, as noted earlier, the rule of law had broken down in the then American colonies. Today a free system of American laws is alive and well despite the best efforts of some. In fact, the rule of law is very strong, as recent political events have demonstrated. This is also something we celebrated the 200th birthday of last year.

This last achievement is perhaps the greatest of all. For in this system Americans can and do daily change the laws by both judicial and legislative action. But until a law is changed, Americans are duty bound to abide by it. For no man is above the law and no man is below it, nor do we ask any man's permission when we require him to obey it.

To the heart of the matter: I agree with you in that a discussion of the pros and cons of the 55 mph speed limit is beyond a letter such as this. In fact, such a discussion is not needed. What is needed is a recognition of the fact that murder, bribery, not using a valid callsign on the ham bands, and yes, speeding, to name a few, are against the law. Not as some people feel, just a good idea you can take or leave.

I, like you, am very proud of people who have the guts to stand up against what is wrong in our society. That is the only way change is accomplished and wrongs righted. This has held true from the patriots at Valley Forge to those who attack social injustice today.

But unlike those at Valley Forge, we do not have to resort to arms and violating the law. Instead, Americans seek to change the law through established legislative and judicial channels. This can range from an individual petition to the FCC, or a judicial challenge to the state Blue Laws, to a legislator down here in Texas trying to *legally* change the speed limit.

I have, however, absolutely no pride in an individual who attempts to either change or enforce the law by breaking it. In fact, I have only pity, for these people are the ones who have missed completely the spirit of the revolution and indeed the nation. Good examples of these folks who, as you say, did their own thing, are the HF bootleggers who have recently been apprehended by the FCC. I am quite sure those arrested think those laws are bum and will do what they can to break them down and get rid of them. But, may I ask, what will happen to radio should they and others continue operating as they were?

It is easy to see the chaos and disorder that would erupt if people only obeyed laws they personally liked. It would not only be the demise of ham radio, order, and justice — it would be the demise of the country.

I am aware, in regards to the WARC, of the one country, one vote rule. I have thought what we as a hobby have needed is a representative to spread the amateur radio cause officially. I also believe, however, that anti-ham feelings could hardly get better by selling one amateur frequency for the purpose of breaking the law. It only adds to the list of excuses available to cast a negative vote regarding amateur appropriations.

For were I a delegate who had read "The Mobile Smokey Detector," I wonder how law-abiding hams were. The case of WR6ABE is a timely, sad, and scary example. Again, those involved with causing the shutdown of that repeater probably were disregarding laws they felt were unnecessary and felt no duty to obey.

In closing, I believe *73 Magazine* has and will always be a leader in the field of ham radio. I am hoping that your code tapes will help me hang a 2nd Telegraph next to my First Telephone (with Radar Endorsement) and replace my Advanced with an Extra. I just hope that in the attempt to lure CBers to a very exciting hobby, we stress good and legal operating procedure, and not another way to beat Smokey. If not, we need not worry about WARC in 1979, for ham radio is finished.

Robert Oler WB5MZO
College Station TX

I disagree with your comments concerning "The Mobile Smokey Detector," Bob. Based on the amount of mail we have received, there are a great number of people using the Smoke Detector for what it is, a microwave receiver. Have you seen any easier method of getting started in amateur microwave communication lately? I doubt it. — Ed.

MUFON

The January issue of *73* with the article titled "The UFO Connection" by David L. Dobbs K8NQN indicates that you still maintain an interest in the UFO phenomenon, even though it may be secondary to your current hobby. Everyone enjoyed the humor of the article, but some thought it was perhaps a fictitious case due to the "spoof" address used in the "open letter" concept. As you probably noted, David simply made minor changes for literary purposes. Amateur radio friends quickly recognized the addressee, especially since Texas and the zip code were correct. Needless to say, it did confuse the post office department in some cities. However, David's address was correct and correspondence will be forwarded to MUFON (Mutual UFO Network, Inc.).

MUFON presently has two active UFO nets operating weekly. The 75 meter net on 3975 kHz meets each Saturday morning at 0800 CST with Marshall Goins WA9ARG in Quincy IL as net control. A 40 meter phone net also meets on Saturday mornings on 7231 kHz with Joe Santangelo W1NXY, in Waltham MA as net control. We invite ham operators interested in the UFO phenomenon to check into these nets not only to share their own UFO sighting experiences, but also to obtain the latest newsworthy UFO events occurring around the United States. Many of the ham operators participating in these nets are also state directors, state section directors, and field investigators for the MUFON.

We publish a 20 page monthly magazine titled *The MUFON UFO Journal*, which covers UFO sighting cases from all over the world. MUFON has members in all fifty states and in thirty-five foreign countries.

We have received, through David Dobbs, several personal UFO sighting reports made by your readers in response to this fine article. I am confident that many of the subscribers to *73* would like to have our correct address; therefore, we would appreciate having this letter published in a subsequent issue.

Walter H. Andrus, Jr. W5VRN
International Director
MUFON

Seguin TX 78155

HILLBILLY NOVICE

I just received my first copy of your fine magazine and, wonder of wonders, it took me over an hour to just thumb through it. What a delight it was for me, a hillbilly Novice, to find all the variety of information and subjects. I even found some I could understand! Hi! It seems that someone must remember what it was like to be a unlearned, untrained, but willing *Novice* when they wrote some of your articles. Please include as many illustrations and pictures on your construction projects as possible as many of us (notice my pride) hams have no experience but want to start someplace.

I certainly got fired up when I read about "A Vest Pocket QRP Rig" by K5JRN in the January issue. When I read that he had just worked Tennessee, 500 miles with a 569 signal report, you know what I did? Yes, I checked my log, but it wasn't me he worked.

As a Novice on 40 meters, one of my best remembered QSOs was with Milt W8TZ in Columbus, Ohio, 70 years young, QRP 3 Watts on a home brew rig he made 30 years ago. QSL said it was in a 3 x 5 card file box and consisted of 117L7 tube and crystal. For me, that was some fun talking to a ham with 56 years experience and wisdom. What progress those "ex-sparkers" must have seen!

So, Wayne, hook up the old key and drift down on the Novice bands sometime and encourage others to do the same. We sure do have a big time there.

Mike Wechsler WA4SPX
Kingsport TN

I'll look for you. — Ed.

MIAMI

We did it one more time: The 17th Annual Miami Hamboree had an attendance of more than five thousand with 64 display booths. The chairperson of the Hamboree was Evelyn Gauzens W4WYR and the sponsor was the Dade County Radio Club.

Guest speaker was Armin H. Meyer W3ACE, Ambassador to Iran and Japan.

Bill Halligan W4AK/W9AC, former owner of Hallicrafters, was on hand to greet some friends from up north.

Of course *73 Magazine* had an excellent display and was one of the most busy booths in the Hamboree.

Larry Price W4RA delivered a couple of speeches representing his position as Southeast Director for the ARRL. The ARRL booth was manned by Terry Williams W1UED and Ellen White W1YL.

The computers booth monopolized a great part of the attention, having unusual coverage by the local TV stations. I am afraid I'm hooked for good and my personal budget is going to suffer great loss this year.

One of the parking lots was open to enlarge the swap meet and fortunately we had some of the best weather of the season.

Albert H. Coya WB4SNC
Miami FL

The Miami Bayfront Park Auditorium had wall to wall hams.

THE 10M SOLUTION

Over the past few months, prices of CB radios have been falling like a rock. It seemed like now was as good a time as any to take advantage of some good cheap radios and put them to some practical ham use. WBØMZD and myself looked over several units and decided on one type for conversion. It is here where we would like to pass on a few suggestions. First, a frequency scheme.

We decided on a scheme which would allow use of as much coverage around the frequencies of 28.6, 28.65, and 28.8 MHz as possible. These areas appear to be the most popular on 10 meters at the present. Our channel versus frequency selection is as follows:

Channel #1 28.550
Channel #2 28.560
Channel #3 28.570
Channel #4 28.590
Channel #5 28.600
Channel #6 28.610
Channel #7 28.620
Channel #8 28.640
Channel #9 28.650
Channel #10 28.660
Channel #11 28.670
Channel #12 28.690
Channel #13 28.700
Channel #14 28.710
Channel #15 28.720
Channel #16 28.740
Channel #17 28.750
Channel #18 28.760
Channel #19 28.770
Channel #20 28.790
Channel #21 28.800
Channel #22 28.810
Channel #22B 28.820
Channel #23 28.840

Those who research this scheme will note that the original CB channel spacings have not been tampered with, which leads us to our second suggestion. We modified *only* the injection or offset oscillators and not the synthesizer. First of all, it is the easiest, cheapest, and most electrically sound way. Secondly, if modification of the synthesizer is done, several problems might occur (depending on type of unit and synthesizer scheme) with the offset oscillators or traps used for filtering of synthesizer products. By converting the offset oscillators only, you have several other important things to gain. You might incorporate diode switching of these crystals with two other crystals to extend coverage in other areas, or, how about modifying these with a varicap to slide in between channels? Note: Not to be confused with sliders, delta tuners, or clarifiers.

We are submitting this frequency scheme to as many of our local clubs as possible. It would appear this is the beginning of something big for 10 meters; local interest is very high. Now would be the time for frequency coordination so we do not have gangland wars similar to some in the beginning of 2 meter repeater days.

Present plans are for breadboarding a scanner similar to the types used on public service monitors and a solid state amplifier for mobile use, although most hams would be surprised to find out just what 5 Watts can really do on a clean frequency.

WBØMZD and myself would like to receive any other plans by individuals or clubs. All letters will be answered. Get on ten cheap and have some fun! Remember: use it or lose it!

Well? – Ed.

10-4?

I've been reading your articles since the days of *CQ*. I probably wouldn't like you if I met you since anyone that drives sports cars and endorses no code licensing has got to have long hair too! But you do have a CB, so you're probably just a native Texan who went "astray."

Most important, however, is your ability to create the best ham rag around. Congratulations to you and the staff of *73* for selecting *useful* construction articles and opening a forum for any idea or opinion – independent of advertiser pressure. Those companies who boycott *73* should also be boycotted. May we see the complete list? Moreover, any decent ad man employed by these firms should quit in protest. After all, since when did advertising policy win out over editorial policy? Other magazines in various fields which allowed their advertisers to dictate their editorial policy soon were out of business!

I buy all the ham mags and hope ol' *CQ* does stay in the game. I don't agree with everything the ARRL promotes and – gosh – I wish they'd change some of the construction articles that refer to parts that are no longer available. Also, I wish *Ham Radio* would hire a rewrite man to modify the construction articles to make them more readily understandable.

Lately, *73* has had the best range of construction articles. The Ham-M modification article was super simple and accomplishes the same thing that other published modifications set out to do, only at half the time and 25% of the cost! The TR22/15 amplifier article was great and *even mine* works. And believe me, if I can build it, anyone can! And I mean anyone!

Keep up the good work. And remember, Wayne, I probably wouldn't like you at all, but tell your advertisers I'm reading every single page – ads included. 10-4?

Don Peak WB5OZZ
Spring TX

THE SHEMYA BLUES

I'm writing *73* because I'll never get an answer from the ARRL. I'm currently on a 2 mile by 4 mile rock 1400 miles west of Alaska and country status is not offered to the hams on this island. How can they give country status to a stilt shack on a reef where the operators have to man boats upon leaving the ham shack? I'd like to see some readers ask the ARRL why one group can get country status and not another. By the way, the QTH is Shemya Island, 176° 10′ E, 52° N on the other side of the 180th meridian.

There are many future hams on the island, but because of recent FCC ruling, the only test I can administer is the Novice. Unless someone wants to spend $600 for plane fare to go to Anchorage, it's impossible to upgrade. Quite a price for anyone to take a test to enjoy a hobby. This means that at best all you can get on this island if you want to be a ham is a Novice. That means no OSCAR, no 20 meters, no VHF, no personal 2m FM with hand-helds, and a very small spectrum filled with foreign broadcast and jammers. With little else to do at this satellite tracking station, you would think many people would like to advance into amateur radio as the only outlet off the Black Pearl of the Aleutian. Alas, alas. There is, however, a Novice course – only a Novice course, though.

80 CHARACTERS

In your Holiday, 1976, I/O Editorial, page 74, you mentioned visiting Southwest Technical Products in San Antonio where you had heard about a couple of fellows who have worked up an 80 character modification of the SWTPC PR-40 Alphanumeric Printer. I've just purchased the whole SWTPC system, less the GT-61 Graphics Terminal and the Printer, and am now looking for an 80 character printer.

Are you planning to publish their modification and if so, when? If not, do you have the names and addresses of these people? Or should I write to Mr. Dan Meyer at SWTPC for more information?

Richard Gay
South Harpswell ME

I'd love to publish an article on such a modification. – John Craig.

OUCH!

I thought *73* readers would like to see the latest advance in space conservation. This shack requires no shelf space, no table, and causes no problems with the YL. All you need is a power plug. Try it!

James Brodsky WB6JXB
Santa Barbara CA

MORE WARC

VE3CYC's personal observations on the future of the 420-450 MHz band ("More WARC," page 9, January *73*) are useful if they cause more hams to think seriously about the preparations for the 1979 WARC.

However, I would like to remove any impression readers may have gained from that letter that the Canadian Radio Technical Planning Board has recommended the 420-450 band be radically changed from its present pattern of use in North America. As a matter of fact, the committee (which was referred to in the letter) did not recommend any changes whatsoever in allocation status between 420 and 450 MHz, despite the near-crisis situation in UHF frequency requirements in other services.

It is worthwhile considering how much of the band in question can at present be "called our own."

In Region 2 of ITU, which includes the US and Canada, the primary allocation is to radiolocation, with secondary allocation to amateur. In the US, the domestic allocation is to government and non-government, with secondary allocation to amateur and amateur-satellite. There are US footnotes which impose a power limitation on amateur use in certain areas, and reinforce protection for radiolocation against interference from hams. In the small segment authorized for amateur-satellite, there is a provision that any harmful interference from hams to other services "must be immediately eliminated."

Where is the part we can call our own?

The Canadian Amateur Radio Federation, in its proposals for WARC 79 preparation, has recommended that 420-430 remain as it is, 430-440 be

assigned worldwide exclusively to amateur, and 440-450 stay shared. This would be an improvement over the present situation, and it would be unrealistic to press for more.

I think it is dangerous to use as proof of need the fact that "an amateur TV repeater takes up more than 12 MHz," especially at a time when a commercial lab has released information about a system for transmitting moving TV images using a fraction of the usual 6 MHz. Haven't we always argued that hams are in the forefront of technical advance?

Bob Eldridge VE7BS

Yes. – Ed.

THE I/O DEBATE

I wish to add my tuppence worth along with WN2DYU and W5GOS. I feel that there has been too much emphasis on computer articles and also articles which assume the wealth of the amateur reading the article. Yes – yes, I know, not all the articles are like this, but it is still pretty bad.

Computers are fine, and I hope to get into them someday, when I can understand them. But with all the jargon printed in *73*, *Byte*, and in *Kilobaud*, how can a newcomer learn anything?

You say computers are closely related to hamming. Well, so is the automobile, especially for two meters. However, I have yet to see an article on how to tune up a car. After all, cars and mobile work *are* related. How about some wood-working articles for those of us who build antennas and radio benches? And how many hams drink tea or coffee when on the air during contests? Where's the article on brewing that ultimate cup of coffee? They ARE related . . . (Sorry, I seem to be stretching a point . . .)

And finally, what is the constant knocking of *CQ Magazine*? I will grant that in the past it was not very good, but in recent months they have been making what looks to me like a considerable effort to print a good magazine. I have subscribed, and I find the articles both interesting and informative. I am not a contest buff nor do I much care about DXpeditions. However, their articles about such things are well-presented and interesting. Finally, they seem to devote a good deal of space to amateur radio in general. So, before casting stones at *CQ*, Wayne, why not read one of their latest issues. No computers, but you still might get something from it.

If it will serve to identify my position a bit further, I no longer subscribe to *QST*, because it is so rankly dull. I am also too young for the ARRL, being that I am under age 87. So, you can see that I have at least some agreement with my Uncle Wayne. But, if *73* keeps being a rich man's ham mag/computer mag, I will drop my subscription to *73* as well. I know nothing about computers, but would *like* to know. However, NOT ONE publication explains computers without using jargon and buzzwords.

David J. ("Walrus") Mann WA6MHD
Redwood City CA

AFD '77

The members of the 143 Communications Flight (Spt), Rhode Island Air National Guard, plan to be operating on Armed Forces Day, May 21, 1977.

Anyone working our club station, K1FCO, will receive a commemorative certificate from our unit provided an SASE and QSL card are sent to us. Our mailing address is: K1FCO, 143 Communications Flight, Rhode Island Air National Guard, T. F. Green Airport, Warwick RI 02886.

We will be operating on the following frequencies: 21.385 MHz – 1400Z to 1800Z; 14.330 MHz – 1400Z to 1800Z; 7.280 MHz – 1400Z to 1800Z; 50.700 MHz – 1400Z to 1800Z.

TSgt Raymond A. Allard K1MFZ
Warwick RI

NØPPI

In October I organized a special events station, NØPPI, for the 2nd annual worldwide conference of People-to-People International. With fantastic amounts of help from several hams and lots of loaned equipment, we had a very successful demonstration and operation. We made several hundred contacts and requested SASEs for QSLs. As yet, I haven't sent out the QSLs because I'm trying to get them printed for little or nothing – I'm the original cheapskate ham and I hate to ask P-PI or the local ham clubs to foot the bill.

So, if you would please tell your readers who worked NØPPI and sent SASEs to please be patient a little while longer, I will soon have a source (hopefully) and will get that special prefix off to them as soon as possible.

Oh – also enclosed is a 3 yr sub (renewal) to your fine mag. Keep up the good work. Thanks much.

Neil Preston WBØDOW
Kansas City MO

YASME

This is a report on our successful YASME DXpedition operation as PJ8KG, Philipsburg, Dutch Sint Maarten, Netherlands Antilles.

Some 7,500 QSOs were made with amateurs in 121 countries. There is a system to the way calls are issued here that is not well known outside the immediate area. There are two DXCC countries in the group. One consists of Sint Maarten (PJ7), Saba (PJ6), and St. Eustatius (PJ5). For these countries, all *visiting* foreign hams are assigned PJ8 calls (usually of their choice). The other DXCC country consists of all the remaining islands: Curacao (PJ2), Aruba (PJ3), and Bonaire (PJ4). For these countries, all visiting foreign hams are usually assigned PJ9 calls of their choice. It normally takes two months for the processing of an application for an amateur license, which must be made on their official form.

People sometimes ask, "What does the YASME Foundation do?" We had a good example at PJ8KG of how the YASME organization (all officers and directors are avid DXers) can help a YASME DXpedition in the field. Three condensers in our transmitter burned out. We managed to get word of our plight to Frank Campbell W5IGJ, an ex-publicity director for YASME. He got replacement condensers off to us by air mail immediately. Within a few days, the defective condensers were replaced and we were back in operation. There have been a number of similar incidents where YASME officers have helped in the licensing and operation of YASME DXpeditions in the field.

Lloyd Colvin W6KG
Iris Colvin W6QL
Netherlands Antilles

BAUDOT TO ASCII

I am sure that you receive hundreds of letters telling you how good your magazine is. And, it really is spectacular. Let the other magazines try to work their way up to the top, if they can. If *73* is an inspiration, the ham fraternity will gain a lot. Amongst several projects I built from *73* articles, I picked my last one, the keyboard project by K7YZZ, for sending you some photos.

Despite the warning from Mr. Hutton on availability of the 5220 BL/N chip, I chose to build the Baudot to ASCII converter using that ROM, as I saw it advertised by some of the companies in the USA. At this writing, I had not yet received the ROM ordered from Tri Tek more than a month ago. So the ASCII part of the keyboard is not yet working.

To build an electronic project in Brazil can be very frustrating, as you don't easily find (if you can find at all) many of the necessary components. So, some imagination and adaptation is usually necessary. As I had only a small piece of double-sided PC board for the encoder matrix, I chose to locate it on the top of the main board. Under it you can see the UART and the Molex pins that will receive the 5220 BL/N. Since I am a "beginner" in putting projects together, you can see that I had to use some jump wires.

Underneath the main board you can see another small board. That is the parallel ASCII to serial ASCII project from another *73* article: W8LNY's. Some small modifications had to be made on both boards to suit my own needs.

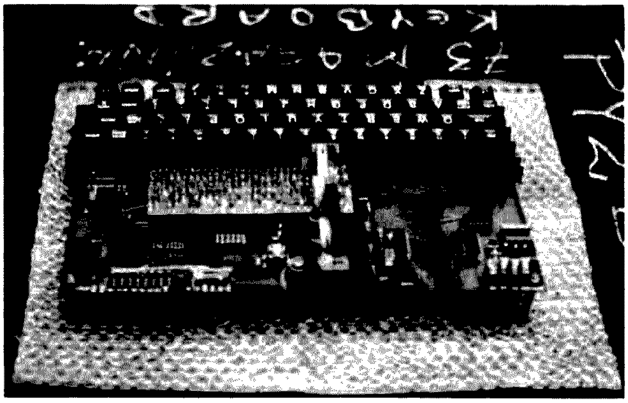
Thank you very much for such an excellent magazine.

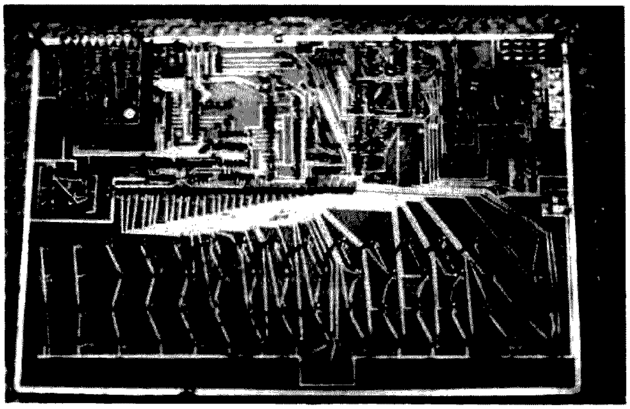
Robério Dias PY2BLA
Sao Paulo, Brazil

HB 1089

We enjoy your magazine and the point you make of speaking out on the issues. I think that if more amateurs would do the same, amateur radio would be (and continue to be) in good shape. Keep up the good work.

In our Oklahoma state legislature at present is HB 1089, "prohibiting the





use of devices to detect radar." I haven't seen a copy of the bill yet, so I don't know what type of microwaves they are talking about, but I assume it's traffic radar.

Some of the amateurs in the area have expressed concern over the principle of state government trying to regulate reception of radio waves, as well as other possible side effects of a bill like this. Here in Tulsa, the amateur and CB community has just had a taste of city government regulations in towers and antennas and is sensitive about the issue.

We would welcome your opinion on the issue. The bill is still in house committee, so there is still time for action.

Charles Frentzel WB5EUK
2704 N. Norwood
Tulsa OK 74115

MA BELL – AGAIN!

The new "Bell bill" in Congress is a threat to phone patches. Each ham should realize the many undesirable consequences including the threat to phone patches in this bill that is now being considered by Congress.

After many years of illegal phone patches, hams can now in various ways legally attach phone patches, telephone answering equipment, tape recorders, computers, and other communication devices to the telephone lines. This may be a short-lived benefit if this new bill is passed.

A very good description of the undesirable effects of the new bill is contained in the January, 1977, issue of *Consumer Reports*. In this article it mentions, "Another section of the Bell bill, as already noted, would strip the FCC of power to regulate terminal equipment; regulation would be turned over to the states. In some states, that shift would wipe away any chance for consumers and businesses to buy and attach equipment without need for the unnecessary and expensive protective module previously required by state regulators at the insistence of phone companies."

It is very important that each ham and all his friends and acquaintances contact their congressman and mobilize influence against the "Bell bill." As in so many cases, we must fight for our rights to have them.

C.W. Tazewell W2GTV
Syracuse NY

BATTING .400

Bravo to Tom Carney WB9RXJ for his letter in Jan., '77, *73*. Nothing is more frustrating for someone new to CW work on the low bands than to establish a QSO and have someone call CQ on top of it. In all the CQs that I have heard, only about 1% even think to ask if the frequency is in use. It should be a requirement for every amateur to memorize chapter 24 of *The Radio Amateur's Handbook*.

As long as I'm on my soapbox: Bull to you die-hards who insist that you aren't a true ham unless you can tap out umpty-ump words per minute CW in order to upgrade. When a baseball player tries out for a team, he doesn't have to hit x number of home runs or strike out x number of batters simply in order to be a left fielder.

I agree with the Advanced theory test and 5 wpm as brought up by WB2BJH. From the way I've heard many Generals and Advanced hams talk on the phone bands, it seems that they spent so much time learning how to tap out the alphabet on a key that they forgot how to speak.

I've heard every ham I know say that in ham radio there's something for everybody. Well, you're wrong, gentlemen. How about certain HF phone privileges for those of us who like to talk rather than tap?

Finally, I am sick and tired of hearing those who knock *QST* and the ARRL. I don't like them either. What's the solution? Mine is: Wayne Green for president in 1980!!

Mark Camp WB6QHZ
Santa Ana CA

THE HUSTLER

OK, Wayne. You are a transparent but crafty hustler. I hereby doff my hat to you.

Here I had tried and failed to get the code mastered, built and tested (and then sold for less than it cost) a complete top-grade station, and let my *73* subscription expire. So just after my oldest son gets assigned to Germany and my buddies start talking about setting up a sked for me to talk to him, you decide to spend a few bucks sending the current tantalizing issue of *73* to selected ex-subscribers. You are a fiend, and I know I am going to learn some new reasons to hate you, because I hereby fall for the bait. Enclosed please find my check for a bunch of code tapes and study guides, and also for another year of *73*.

When I start finding out how dang tough it is to learn the #$%&* code, despite your overtures to the contrary, and start spending money like a drunken sailor to get the ham shack "properly" fitted with gear and the necessary outside wires and sticks, you can expect to start receiving some more hate mail. You will probably deserve it.

Bill Sill
Tunkhannock PA

THE IVORY TOWER

Regarding the letter by Bob Welsh (reprinted from *LERC*), page 13 in the January, 1977, *73*, paragraph three: I think it is a bit unfair to say the ARRL has been duped into helping the FCC clean up the CB mess because of the following considerations. First, the CBers who are potential hams are generally the more serious practitioners of the hobby and also the least likely to participate in the childishness that occurs on 11 meters (especially channel 19). Removing these people from the CB fold is not likely to clean up the mess. CBers interested in amateur radio are usually the more technically minded members of the group and in that regard would be an asset to amateur radio. Finally, amateur radio is also not without its impolite, even childish members – for instance, see the note in January, 1977, *73*, page 208. entitled "Tragedy on Mt. Wilson."

I think it is time for hams to abandon the ivory tower. A first step might be to acknowledge that everyone is human and every group, society, whatever, has its mavericks.

Bruce Ott VE7BOT
Port Coquitlam BC

ON BEING HUMAN

It is great to know there is still at least one organization that has *humans* in it!

I like *73* so much I ordered a subscription for my son WBØVEZ, with instructions that the bill be sent to me. Some time later, I got a second copy of the Holiday issue with a handwritten mailing label on it. Figuring that my instructions had been misunderstood, I wrote, explaining the whole situation. A short time later a friendly note came.

Nowadays, it seems, the usual response to a letter of complaint or inquiry is either (1) a pre-printed form which leaves doubt that the letter was ever read, or (2) a letter which has been dictated, transcribed, and typed on a fancy letterhead (and cost a bunch of money).

I like your way best. It's not very elegant, but it is refreshingly personal, to the point, and very effective. Keep up the good service and personal attention!

Donald Inbody WAØPBQ
Overland Park KS

MORE 10M

Interesting note: While talking on 20m about 10m CBers, a fellow on the east coast said his club submitted a proposal to *QST*. The answer was, "We don't want anything to do with it!!"

The more I think of it, what other answer (from *QST*) would he get?

73 and *Kilobaud* are the best!

Ken Lowrance WRØMZD
Tim Haake WAØTSY
St. Charles MO

We are receiving many proposals for a 10 meter band plan based upon converted CB transceivers. Watch for them. I'm expecting your comments. – Ed.

REASSESSMENT

Today I took and passed my amateur Extra exam, thanks in part to the *73* 20+ wpm code tape. In answer to your question, I figure I spent about 10 hours with the tape. Since I last took a code exam for my General some 20 years ago, I don't know what

my "starting speed" was, but probably around 18, since that is what most hams seem to use.

I have but one suggestion for improving the code tape: put in some longer strings, perhaps 8-12 characters long. The exam I took had words like "disaster" and "shield" which are (a) relatively long, and (b) have an effective speed around 28 wpm for the 8 character burst. (I was afraid I'd have to copy "reassessment," but they didn't put it in – or if they did, I missed it!)

Thanks for a whole bunch of super stuff in general, and the code tapes in particular.

Frank Bates W6IPB
San Jose CA

A REAL WINNER

My son Robert, who is a specialist in microcomputer programming and who works with a local computer firm, just brought home issue #1 of *Kilobaud*. I must say that I am impressed! I have seen *73* grow from a small beginning into the most prestigious ham publication by far, but *Kilobaud* seems to be well up the ladder with its very first issue. I'm too old a canine to understand all of its intricacies (or too lazy to learn?), but my son, who was fortunate to have had a very smart mother, says it's a real winner. I am sure it will enjoy fully as great a success as *73*.

Keith Berens W6CWU
Orange CA

MORE 80M FOLLIES

Thought I'd drop you a line and let you know how much I enjoy your magazine. I wish I had known about it a year ago so I could have saved myself a lot of money and messing around with store purchased antennas. I don't know if any other people have heard some of the garbage I've heard on 80m or not, but I thought I was back on 11m again. I don't know if they were hams or not because no call letters were being used. I would like to let you know of a super amateur radio shop in the midwest – it is Burghardt Amateur Center, Box 73, Watertown SD 57201. Keep up the fine work on the magazine and the articles.

Robert W. Todd WBØTWN
Jamestown ND

Special Report

by Bill Pasternak WA6ITF

The first time I commented on SAROC in Looking West, I stated that this convention was unlike any other, in that it was not the convention but rather the atmosphere of Las Vegas that was the real drawing card. When compared to a convention such as Dayton, it can't compete. It is different from any other convention that I have ever attended, and the only fair way to judge SAROC '77 is against previous years. Based on that criterion, I found myself disappointed this year.

Las Vegas, Nevada, is known worldwide as the "Live Entertainment Capital of the World." Twenty-four hours a day, "Vegas," as its friends call it, is a gold mine of entertainment, with some of the most lavishly staged extravaganzas to be found anywhere. There are few well-known club entertainers who have not played there, because playing "Vegas" means that an entertainer has indeed "made it."

Not that this is the only lure of Las Vegas. Gambling is legal and open to all of legal age twenty-four hours a day. Put these two factors together, and you can see why a trip to Las Vegas has the appeal it does – and why this city has become one of the world's most visited vacation spots.

Sharon and I like to go to Vegas when a good excuse such as SAROC comes up. Therefore, in my opinion, it is Las Vegas that makes this convention. Were there a less exciting environment, I doubt if it would go.

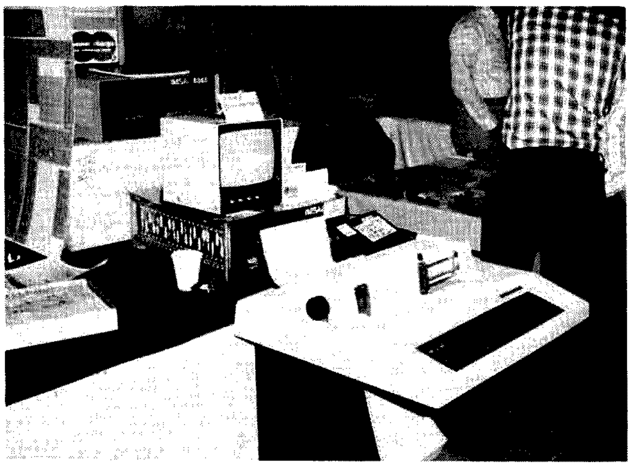
This year, despite a reported record registration, more exhibitors than last year, a record number of portable repeater and remote-base systems, and more hospitality rooms, the overall attitude of the attendees seemed very subdued. While many seemed to be enjoying themselves, there was an "air of apprehension" permeating things. It was definitely a lot quieter than it has been the last two years.

Since I am one person and cannot be everywhere at once, I try to have either a friend, my cassette tape recorder, or both, to help cover things. This year the assistance came not only from my Panasonic RQ-309 and RE-15 microphone, but also from a lot of fellow amateurs. (Thanks.)

Although the overall number of companies exhibiting was up a bit, it was interesting to note that a number of regulars were missing. The most notable change this year was the larger participation by those offering computer-related hardware applicable to amateur radio – and the share of the crowd that they were drawing.

In that department, the most interesting and attention-getting display was the booth operated by HAL Communications (staffed by their highly knowledgeable sales manager Ken Sartain and his associates). If you have been around for any length of time, you realize that HAL (Urbana, Illinois) pioneered the interface of DP hardware to amateur radio. HAL is one of the new breed of companies that has found that keeping an ear open to what amateurs want and need leads to success. Needless to say, their video display units and peripherals attracted a lot of attention.

So did the new Curtis System 4000 Ham Computer, a device that is definitely going to open up a whole new era in amateur operation. Not only does it have the ability to send CW using an integral keyboard, but it also will read and display on a screen received CW at a rate of up to 250 words per minute. It also tells you just how fast the other guy is sending, to boot. If that were not enough, the keyboard also functions as an ASCII terminal, either half or full duplex. Still not satisfied? Well, Curtis intends to have a few software goodies available: storage (for the 4000) for 10 fifty to one hundred character CW messages, complete contest station management, automatic beam direction based on the other guy's callsign, DX forecasting, Oscar and other satellite orbit predictions, and lots more. Computers are an interesting hobby and are applicable to amateur radio . . . hmmmm . . . a note to Curtis Electro Devices at PO Box 4090, Mountain View CA will bring more info.



"More Computers for Hams": IMSAI's interface to amateur radio.

In the basic ham hardware department, the new all solid state Century 21 CW transceiver really attracted my fancy. Maybe it's because, after 15 years as a ham (most of the time spent in the world above 50 MHz), all of a sudden the challenge of low band CW has hit me. The size, price, and features of the Century 21 sure caught my eye. At a first glance it looks like just about any other HF SSB transceiver, and you have to get in really close to realize that there is no mike jack or phone provision. It's a complete 70 Watt, all solid state, 80 through 10 meter CW station – and "complete" means built-in power supply and speaker. Suffice it to say that for $289 the features contained in this box (backed by a company whose guarantee of quality is unsurpassed) are well worth the investment. Write Ten-Tec, Sevierville TN 37862 for more info. This has got to be the perfect setup for a Novice or the Technician who wants to make use of his newfound low band privileges.

In VHF, Midland not only showed its complete line of two and 220 radios, but also drummed up a lot of interest in its new line of VHF marine equipment. If I were to single out one manufacturer that has helped in the overall development of 220, I would have to pick Midland. I'll bet that the majority of 220 repeaters these days are built from the guts of the famed 13-509, and that says a heck of a lot for both the radio and the people selling it. Not that it stops there. How many repeaters have come into being thanks to Midland's RSVP program? How many companies are willing to take part of their profit and donate it directly back to the amateur service with no middle man? That's the kind of manufacturer support that amateur radio needs. Needless to say, their new synthesized radio for "two" captured the eye of many of us. A note to Midland at PO Box 1903, Kansas City MO 64141 will bring a complete catalog and the name of your closest dealer. If you do write, please don't forget to say thanks for the direct support that they are showing us.

How would you like to be able to pump 200 Watts into a window screen in Las Vegas and work Long Island, New York, on 20 meters? This was actually done at SAROC by one of the visitors who passed by the SST Electronics booth and purchased one of their $29.95 Model SST-T-1 random wire antenna tuners. One of these is just a little green box, 3" x 4-1/4" x 2-3/8", that I have found will load my old Globe Scout Deluxe into almost anything. I saw it there, but it was not until a week later that I got one for myself – I now understand why this little unit is becoming so popular. Eleven states on 40 CW in two days is nothing to sneeze at when your antenna is the feedline to a six meter vertical. No wonder SST did such a brisk business at SAROC. For the Tech who wants to make use of his Novice privileges without putting up a new low band antenna, or for the ham who can't put up a really good antenna, the SST-T-1 can be a godsend. It has been to me. SST Electronics is at PO Box 1, Lawndale CA 90260, in case you are interested in more info on this product.

Not all the new goodies were to be found on the exhibit floor, however. In fact, one new radio that I predict you will be hearing a lot more about real soon was not publically shown. However, we were able to get a sneak preview and a few photos. The radio is called the FM-144-DX, and the man behind it is none other than the foremost pioneer of amateur VHF communication, Mr. Ed Clegg W3LOY. Ed, who helped sponsor this year's Mt. Wilson Repeater Association Aloha Hospitality Center, not only brought along his inexpensive crystal-controlled 12 channel two meter radio, the Mark 3 (which was on operational display in the MWRA room), but had the FM-144-DX with him as well.

This little gem is fully synthesized, and has LED readout, concentric knob quick change channel selection, standard plus/minus 600 kHz offset, and provision for other offsets that are switch-selected (not to mention a host of other features that will make it a hard radio to beat). Best of all, Ed tells me he hopes to market it at a price that will make it affordable to most amateurs. Keeping in mind the track record of Ed Clegg, the fact he was building and marketing VHF equipment before most companies thought of going in that direction, the fact that his equipment is usually a bit ahead of the competition, and the knowledge that a fellow amateur stands behind the equipment and its guarantee, I'll be willing to bet that when the FM-144-DX hits the market, it will gain quick and widespread acceptance throughout the amateur community. I know that I plan to buy one to replace a dying T-43-GGV in the '71 Torino, and this decision is based on the few minutes I had to play with it in Ed's room at the Sahara. It's the personal confidence that I have developed over the years in "the man and his radios," starting in the very early '60s when I bought my first '99er – a very personal thing on my part.

The convention peripherals, such as hotel service, rooms, hospitality rooms, and portable repeaters, are what make or break any convention. I heard the usual number of complaints about rooms that had been paid for not being ready, and in some cases not available; about poor service on the part of the hotel; about people being turned away. If this is true, it sure didn't happen to any of our group. Our block of about 30 reservations was not handled through the SAROC convention committee, but rather as a direct group reservation through the Hotel Sahara. Not one person in our group was turned away, and in every case the rooms were available when our contingent arrived. Moral: Sometimes it pays to do one's own legwork. In my case, arrival was at 1 am on Friday morning; we were in our room by 1:20 am. Not bad for

"midnight service." Based on that, I find it rather hard to place the blame for any snafus on the hotel, and I am interested in knowing where the problem really lies. The people running the Hotel Sahara always seem to go out of their way for us when we are in Vegas, and I guess that's one reason we keep going back. If you had a problem, drop me a letter with full details and I will see that it's forwarded to the proper people at the Sahara. I've had the chance to talk with people in management there, and I get the distinct impression that if something is awry, they would like to know about it so that it won't happen again. They have a lot of pride in their place.

There were a few new hospitality rooms this year and a lot more portable repeaters. One even showed up on 220! I would estimate that there were about 25 portable repeaters. Again this year, the best portable repeater award goes to Kirk Nemzer WB6EGR and his crew for their 147.435/146.40 system. It had a coverage of over 70 miles, and turned out to be the most heavily used of all the portable systems. A good number of the portable systems were on 450 and were kept low key.

One of the criteria that you should use to judge the level of fun at SAROC is to listen to 146.94 in the evenings — especially Friday and Saturday nights. There has always seemed to be a direct correlation between .94 activity and the enjoyment level at the convention. Unlike past years, .94 was quiet. Again, the overall temperament of the crowd was down considerably from the past. Many of the people I talked with during my rounds of the various hospitality rooms complained that there was nothing really new here that they couldn't see at their local radio store. And the bargain hunters found no bargains whatsoever.

At SAROC, anything free, such as technical sessions and seminars, is kept to an absolute minimum. Too bad. It would be a great place to really get into VHF/UHF developments, such as the use of circular polarization to minimize path loss, computers for remote control procedures on repeaters and remote bases, etc. SAROC has few technical sessions.

I did enjoy a talk given by Mr. Hartley Postlethwaite WA6CQW, founder and director of the HAPPY FLYERS organization.

Hart spoke on a subject near and dear to every repeater owner's heart these days: direction finding technique as applied to tracking down a device known as an ELT, or Emergency Location Transmitter. ELTs are carried aboard every aircraft. They are designed to trigger on impact and emit a signal so that a downed aircraft can be located. As a pilot, Hart has been involved in ELT location for a few years. The techniques he has developed have appreciably speeded up location of these devices and thereby saved many lives. As he explained, while the hardware and technique were specifically developed to aid in ELT location, the same hardware techniques do find repeater jammers. Drop a note and SASE to the HAPPY FLYERS, 1811 Hillman Avenue, Belmont CA 94002.

Dick Everett, Assistant Chief of Safety and Special Services of the FCC, was on hand to answer questions, such as:

Q. "Would the elimination of the repeater subbands mean that 15 could be repeated to 20?"

A. "Yes."

Q. "How do you rationalize a closed repeater?"

A. "There is nothing in the rules that says that one amateur *has* to provide a repeater for another."

The main speaker at the ARRL Forum was from an organization known as the Personal Communications Foundation. Its Director/President is one of my valley neighbors, Mr. Jon J. Gallo WA6PTM. You will note that the "6s" seem to be taking the bull by the horns, going out and getting things done.

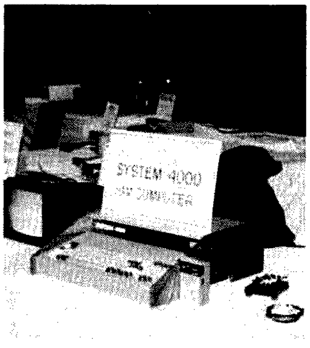
With over 7,000 legal matters involving amateur radio in 1976 alone, and with the average cost per matter being around $3500 (and going up), it is easy to see how even the simplest of such legal proceedings can give instant grey hair to any ham who might become involved.

The concept of PCF is to do the hard job, that of legal background and documentation work, so that an attorney in need of such input can be provided with the data. This will thereby cut the overall cost to the amateur substantially. An estimate given was that a legal action that now would cost $1000 might drop to as low as $300, with PCF aid. PCF, however, states that while it will provide such material, it will not act to represent an amateur in court. Its function is to provide advice and research.

All this does not come cheap. There will be a WATS telephone, and office and secreterial costs, plus what it costs to reproduce the documentation packages and get them mailed. If one out of every three amateurs were to donate a dollar, all costs of the PCF could be met. How about it, readers? Here is your chance to act directly and do your part.

This nonprofit corporation is headed by a 24-member Board of Directors, made up of judges, attorneys and legal professors who also are devoted amateurs like you and me. The least we can do is support their work by kicking in a few bucks. The address is Personal Communications Foundation, c/o Carl Markov K6RLP, 915 Lancaster Boulevard, Lancaster CA 93534.

I mentioned that there were more than the usual number of hospitality rooms this year. Last year, the MWRA's (with Bill Orenstein at the helm) won overall acclaim by having most in attendance. Both MWRA and Bill were back again this year, with a format that not only featured a quiet relaxing spot, but also such added features as an "Amateur Radio Theatre" that showed regular screenings of Dave Bell's "Moving Up To Amateur Radio" and an operational exhibit of some of the Clegg VHF line (with Ed Clegg himself as special guest). It was never jammed, never



The Curtis System 4000 Ham Computer.

noisy, and the most relaxing spot at SAROC this year — just as it was last year. Bill gives a lot of the credit for the success of the room to the staff that runs the Sahara.

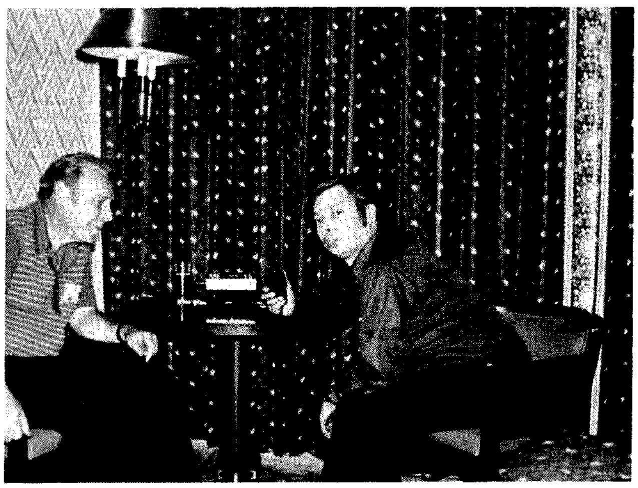
The Palisades Amateur Radio Club (PARC), of Culver City, California, pulled off a big surprise: the PARC hospitality center. This was an after-arrival idea of Wayne Maynard WB6BFN, Shelley Chelsey WB6KED and Don Root WA6HJW. Pooling their collective resources, they came up with a convention get-together spot that was hard to beat. I never noted a moment when it was empty or when anyone was not having a good time.

The Spectronics FM hospitality room is always worth a visit. Spectronics' Art Householder was ill and unable to make the trip. Captain Dick McKay K6VGP, who visited Art recently, said that he is recovering, but still must take it easy for a while. Not that Art wasn't well represented. Well armed with his famed "Drinkie Talkie," "Squeak" Porray K7RBM took the reins this year and put out the kind of hospitality that this room is famed for. It's not uncommon to find people there whom you will see nowhere else at SAROC. True-blue FMers will travel from all over just to spend a few hours in this particular hospitality suite.

I was not alone with my feeling about SAROC. Wherever I went throughout the three days I spent at the convention, amateurs kept coming to me to say that there was "something lacking this year," that "things were just too political," that they had come for a good time and not to have the ARRL preach to them. One guy came to me up in the MWRA suite and told me that he had been to many conventions including Dayton. He said he had always liked SAROC because it was different than the rest, but if it were going to become like another ARRL Division Convention, he would not return. I do feel that the politics should be left to the politicians, so that the majority of attendees can accomplish what they came for: a Las Vegas vacation shared with a lot of their fellow amateurs. While I do not challenge the right of the ARRL to take part in this convention, I do feel that if they had left their "New England Formal" attitudes back home and picked up a bit on "Southwest Casual," they might have accomplished a lot more for the ARRL image and alienated fewer of this area's VHF/UHF-minded amateurs. Excepting shows or formal dinners, Las Vegas is not a formal town. Most of the Southwest isn't. When one is super-formal out here, one stands out like the proverbial sore thumb. A casual friendly approach goes far in winning both friends and support in the Southwest.

Well, there you have it: SAROC '77 in no way matched its own past. Bigger does not always mean better and numbers in attendance are not the real material that makes for an outstanding amateur radio get-together. In my opinion, based upon the three years I have personally attended, I do feel that SAROC needs a bit of changing. It should bury the surface politics. It needs a lot more emphasis placed on technical presentations, so as to interest technically-minded amateurs. Amateurs enjoy exploring new concepts and new ideas. By making sure to have experts and time made available for them to be heard, we can look to the future of communication and explore these new frontiers.

I am not an expert on conventions, but I do know when I am having a good time. In the past, SAROC has offered that to me. This year I was disappointed.



Ed Clegg gives 73 a preview of his FM-144-DX 2m synthesized FM unit.

CONTESTS

Editor:
Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

WISCONSIN STATE QSO PARTY

Starts: 0001 UTC Sunday,
April 3, 1977
Ends: 2359 UTC Sunday,
April 3, 1977

Please note that the dates originally submitted (March, *73*) were incorrect.

SIX METER GROUND WAVE CONTEST

Starts: 0300 GMT
Sunday, April 2
Ends: 0700 GMT
Sunday, April 2

The second annual contest is sponsored by Global Research and is open to all amateurs worldwide on all modes: SSB, CW, FM, AM, SSTV, RTTY, and FAX. Any six meter contact is valid. Skip stations do count in the event the band is open, but they only count ½ point each no matter where the station is located.

SCORING:

For scoring purposes, there are four zones defined by the distance between your QTH and the station contacted. Zone definitions and QSO points for contacts with each zone are as follows: Zone 1, stations within 25 miles of your QTH – 1 point/QSO; Zone 2, stations 25 to 50 miles from your QTH – 2 points/QSO; Zone 3, stations 50 to 75 miles from your QTH – 3 points/QSO; Zone 4, stations over 75 miles from your QTH – 4 points/QSO.

LOGS:

Show your name, call, address, ARRL section, and input power. Mobiles and portables must show actual locations. For each station worked, show: call, ARRL section, zone (as defined above), time, and points scored. Show your total score, sign the log, and submit to: Phil Caruso K9DTB, c/o Global Research, Contest Chairman, PO Box 271, Lombard IL 60148. Logs must be postmarked by May 3.

TENNESSEE QSO PARTY

April 2-3

7th annual party sponsored by Tennessee Council of Amateur Radio Clubs.

PERIODS:

Saturday, April 2, 2100Z, to 0500Z, Sunday, April 3.

Sunday, April 3, 1400Z to 2200Z.

Bonus period April 3 from 0500Z to 0600Z for out of state stations only to work Tennessee mobile and portable stations only on 75 meters.

EXCHANGE:

Tenn stations send signal report and county. Out of state stations send signal report and state, province, or country. Work same station different bands or county if mobile or portable.

SCORING:

Separate CW and phone contests (one point each contact). Tennessee stations – QSO points times sum of (different state including Tennessee plus different provinces plus different Tenn counties).

Out of state stations – QSO points times number of different Tenn counties.

Bonus points – 200 extra points to mobiles and portables for each county operated outside home county.

FREQUENCIES:

3550, 7050, 14050, 21050, 28050, 3725, 21125, 28125, 3980, 7280, 14280, 21380, 28580.

LOGS:

Date/time in GMT, station worked, band, mode, exchange, and score. Use separate log sheet for each band over 25 contacts; contestants with 100 contacts or more must submit cross check sheet similar to ARRL operating aid No. 6. Logs must be legible to avoid disqualification.

AWARDS:

Plaques to top phone and CW scores in Tennessee, to winning mobile, to winning portable, and top score out of state. Certificates to every station sending log with 15 contacts. Repeater contacts not allowed. Mobiles compete against mobiles, portables against portables. Minimum 10 contacts each county to earn bonus points.

Tennessee stations on phone call "CQ Tenn QSO Party," on CW "CQ Tenn" or "TEST" – variations to encourage contacts from non-contestants will result in disqualification.

Mailing deadline May 1, 1977. Send self-addressed stamped envelope if eligible for certificate to Dave Goggio W4OGG, 1419 Favell Dr., Memphis, Tenn 38116. Every entry will receive summary along with certificate if eligible.

COMMON MARKET DX CONTEST

CW
0600 GMT to 2400 GMT
Saturday, April 2
Phone
0600 GMT to 2400 GMT
Sunday, April 3

The purpose of this contest is to increase the activity of radio amateurs in the Common Market of Europe and to establish as many contacts as possible during the contest periods between stations of the Common Market of Europe and the rest of the world. All bands 80 to 10 meters may be used on the appropriate mode. Contest call is "CQ CM" or "CQ Common Market." Entries may be in either of the following classes: Single op, all bands; Single op, low bands (80 + 40); Single op, high bands (20-10); Multi-op, single TX, all bands only (also club stations).

EXCHANGE:

RS(T) and QSO number from 001.

SCORING:

Non-Common Market stations: QSO with CM = 5 points; any other EU station = 2 points. Common Market stations: QSO with CM = 1 point; non-CM, EU = 2 points; non-CM outside EU = 5 points; QSO with own country = 0 points but ok for multiplier.

Multipliers: One point for each band. For non-CM, CM countries = Belgium, W. Germany, Italy, Denmark, Great Britain, Luxembourg, Ireland, the Netherlands, and France. For Common Market stations: each country in the world, following DXCC list. Claimed scores is total QSO points times total multiplier as usual.

ENTRIES:

Separate logs for each band; show date/time in GMT, exchange, points, and multipliers. Summary sheet must include signed usually-used declaration that all rules/regulations observed. Mail by April 30th to contest committee: Michel Le Bon ON4GO, Chee de Wavre 1349, B-1160 Brussels, Belgium. Certificates to highest scoring single op in the CM on each mode and to highest scoring single op outside CM on each mode.

ZERO DISTRICT QSO PARTY

Starts: 2000 GMT
Saturday, April 2
Ends: 0200 GMT
Monday, April 4

Organized by the Mississippi Valley Radio Club, this contest covers a lot of territory and should create a lot of activity. Stations outside of Zero district will work Zero district stations only, but Zeros may work both in and out of district stations. The same station may be worked once on each band and each mode.

EXCHANGE:

QSO number, RS(T), and QTH. QTH is county and ARRL section for Zeros, ARRL section only for all others.

SCORING:

For Zeros – total QSOs multiplied by (ARRL sections + Zero counties + DX counties) worked. Others – total QSOs multiplied by (Zero counties + Zero sections).

FREQUENCIES:

3560, 7060, 14060, 21060, 28060,

3900, 7270, 14300, 21370, 28570, 3725, 7125, 21125, 28125.

ENTRIES & AWARDS:

Beautiful four color certificates will be presented to the General class section high scorer and to the Novice/Tech class section high scorer. Mailing deadline for entries is May 15th, to: Mississippi Valley RC, 3518 W. Columbia, Davenport, Iowa 52804. Include an SASE for results.

ANNUAL APRIL QRP
QSO PARTY
Starts: 2000 GMT
Saturday, April 2
Ends: 0200 GMT
Monday, April 4

The contest is open to all amateurs and is sponsored by the QRP Amateur Radio Club International, Inc.

Stations may be worked once per band for QSO and multiplier credits. Each member QSO counts 3 points, non-member QSOs 2 points. Stations other than W/VE count as 4 points per QSO. Multipliers are as follows: More than 100 Watts input power — x1; 25 to 100 Watts — x1.5; 5 to 25 Watts — x2.0; 1 to 5 Watts — x3.0; less than 1 Watt power — x5.0.

Final score is QSO points times total number of states/provinces/countries *per band* times power multiplier.

EXCHANGE:

Members — RS(T), state/province/country, QRP number.

Non-Members — RS(T), state/province/country, power.

FREQUENCIES:

CW — 3540, 7040, 14065, 21040, 28040.

SSB — 3855, 7260, 14260, 28600, 21300.

Novice — 3720, 7120, 21120, 28040.

All freq's +/- 5 kHz.

ENTRIES:

Send full log data, including full name, address, and bands used. Indicate equipment, antennas, and power used. Include a #10 SASE for results. Logs must be received by May 30, 1977 to qualify. Send logs to: E. V. Sandy Blaize, W5TVW, 417 Ridgewood Drive, Metairie LA 70001.

Certificates will be awarded to the highest scoring station in each state/province/country. Other places depending on activity. One certificate for the station showing three "skip" contacts using the lowest power.

COUNTY HUNTERS SSB CONTEST
Contest Periods:
0001 GMT Saturday, April 16 to
0800 Saturday, April 16
1200 GMT Saturday, April 16 to
0800 Sunday, April 17
1200 GMT Sunday, April 17 to
2400 GMT Sunday, April 17

Please note two four hour rest periods!

This is the 6th annual contest sponsored by the Mobile Amateur Radio Awards Club, Inc. Mobile stations may be worked each time they change counties or bands, but if worked again from the same county on a different band count for point credit only. Mobile stations contacted on a county line count as one contact but two multipliers. Portable stations that change counties during the contest may be worked for both point and multiplier credit from each new county. Fixed stations may be worked by other fixed stations only once during the contest regardless of bands. Repeat contacts between fixed stations on other bands are not permitted! Fixed stations may be worked by mobile/portable stations each time they change counties or bands. Repeat contacts between mobile/portable stations are permitted provided they are on a different band or county.

EXCHANGE:

Signal report, county, and state (country for DX). Mixed code contacts are permitted provided that one station is on SSB. (Mobiles please keep an ear for CW county hunters calling!)

FREQUENCIES:

3920-3940, 7220-7240, 14275-14295, 21375-21395, 28575-28595.

Please note: This year there will be a "mobile/portable window" of 10 kHz on the following frequencies: 3925-35, 7225-35, 14280-90. Mobiles/portables will be in this 10 kHz segment and fixed stations are asked to refrain from calling "CQ Contest" in this segment. After working mobile/portable stations in the "window," fixed stations are requested to tune and work other mobile/portable stations or QSY to the outer edges of the suggested frequencies to call CQ or work other fixed stations in the contest. This will allow the mobile/portables running lower power a chance to be heard and worked in the contest.

SCORING:

Contact with a fixed US or Canadian station = 1 point. Contact with DX stations (including KL7 & KH6) = 5 points. Contact with mobile/portable stations = 10 points. Portable stations are defined as operating from another temporary location for contest purpose. Multiplier is total number of US counties plus Canadian stations worked; take credit for a county only the 1st time it is worked. A Canadian station counts each time it is worked. Final score is total number of QSO points times total number of different counties and VE stations worked.

ENTRIES:

Logs should show date/time in GMT, station worked, report exchanged, county, state, band, claimed points (1, 5, or 10), and each new multiplier numbered. Official log sheets and summary sheets are free for a #10 SASE or SAE and appropriate IRCs from John Ferguson W0QWS, 3820 Stonewall Ct., Independence MO 64055. Submit all entries to the same address no later than June 1st to be eligible for awards; DX should use air mail.

AWARDS:

Plaques to highest scoring fixed US or VE, DX, mobile, and 2nd mobile certificates to top 10 fixed and mobile stations in US and VE and to the highest scoring DX in each country. Only single operator stations are eligible for these awards, but multi-op certificates may be issued if merited. A station may enter as both fixed and mobile, but separate scores are required.

RESULTS

RESULTS OF 1976 CARTG ANNUAL W/W
RTTY DX SWEEPSTAKES (OCT 1976)

Following is a list of the top 10 places that each received plaques donated by various groups:

I1PYS	1,955,244 points
W3EKT	1,584,380
CT1EQ	1,562,660
W4CQI	988,612
CE3MA	928,988
K8JUG	794,928
KH6AG	794,015
WD8CPU	787,695
W1GKJ	739,344
K0JWX/6	699,900

W3EKT won top US plaque while VE2JR won top Canadian plaque. VK3SG won "Green" RTTY high score for his first time in. Paul Menadier of USA won top SWL printer plaque. W1MX won top multi-op score.

Many other certificates were awarded to the top scores in each USA and Canadian district, and each DX country.

103 logs were received from 49 countries with 25 stations working WAC during the contest period. Looked like a good showing from the USA!

RESULTS

RESULTS OF 1976 DELAWARE QSO PARTY (NOV 1976)

High scoring DEL station — K3YHR with 20,605 points.
High scoring out of state station — AC7UIC with 450 points.

Out of State Scores:

ARIZ	AB7BQN	225
CA	AA6MQS	25

BERMUDA AMATEUR RADIO CONTEST

Starts: 0001 GMT April 16
Ends: 2400 GMT April 17

Sponsored by the Radio Society of Bermuda. Operate no more than 36 hours of the 48 hour contest period. Off periods to be clearly logged and each period to be of not less than 3 consecutive hours. All stations shall be single operator only and must be operated from their own private residence or property. Each station may be worked only once per band regardless of mode. Use all bands 80 to 10 meters, but no cross band or cross mode contacts permitted.

EXCHANGES:

All stations exchange RS(T) and following: UK – county, US – state, VE – province, Bermuda – parish.

US and VE stations must exchange reports with UK and Bermuda stations only. UK stations must exchange reports with US, VE, and Bermuda only.

SCORING:

Each QSO = 5 points. Multiplier for all stations outside Bermuda is the total number of VP9s worked on each band. The same VP9 can be worked on all bands. For Bermuda stations, it is the total number of states, provinces, and counties worked on each band.

AWARDS:

Top scorer in each state, province, and county shall receive a certificate. Trophy to top scorer in VE, US, and UK. Round trip air transportation plus accommodation will be provided to overseas winners to enable them to receive their awards.

ENTRIES:

All dates and times in GMT. All contestants to check for duplicates and to compute their own scores. Sign a statement that all rules and regulations have been observed. Each page must be clearly marked with call, name, and address, and must be received by the contest committee before June 30th. Send entries to: PO Box 275, Hamilton 5, Bermuda.

RESULTS

RESULTS OF THE 1976 DELTA QSO PARTY

Plaque Winners as follows:

High score Delta Div = WA5KOD/5 with 33,592 points.
High score outside Delta Div = WB4OGW with 10,360 points.
High club station = WB5RHX with 21,480 points.
High portable station = K4LTA/4 with 11,340 points.

First place winners in each Delta Div as follows:

ARK	WA5KOD/5	19,698
LA	WB5RHX	21,480

FLORIDA QSO PARTY

Contest Periods:
1500 to 2000 GMT
Saturday, April 16
0000 to 0500 GMT
Sunday, April 17
1400 to 2400 GMT
Sunday, April 17

This is the 12th annual QSO party sponsored by Florida Skip. Phone and CW are separate contests. The same station may be worked on each band for QSO points. FLA stations may work other FLA stations for QSO points only.

EXCHANGE:

RS(T) and QTH-county for FLA; state, province, or country for others.

FREQUENCIES:

Phone – 3970, 7270, 14317, 21370.

CW – 3570, 7070, 14070, 21070.

SCORING:

FLA stations count 1 point per QSO; multiplier is sum of states (49 max), provinces (12 max), and DX countries (12 max). Maximum multiplier is 73. FLA mobiles and portables on emergency power and running 200 W or less multiply total score by 2. All others count 2 points per FLA portable/mobile station worked; 1 point for fixed FLA QSOs. Multiplier is number of different FLA counties worked (67 max).

AWARDS:

Certificates (phone and CW) to top single operator score in each state, province, and DX country, also each FLA county. Five plaques also to be awarded to high single op in FLA and out-of-state, phone and CW, and to FLA club with highest aggregate score.

ENTRIES:

Stations may be disqualified for various reasons – improper reporting, excessive dupes, errors in multiplier lists, etc. – at discretion of the contest committee. Anyone disqualified this year will be barred from the contest next year. A summary sheet is requested showing scoring and other pertinent information. Also include your name and address in BLOCK LETTERS, and a signed declaration that all rules and regulations have been observed. Include a 13¢ stamp for results. Mailing deadline is May 30th. Mail to: Florida Skip Contest Committee, PO Box 660501, Miami Springs FL 33166.

PACC CONTEST

Starts: 1200 GMT
Saturday, April 23
Ends: 1800 GMT
Sunday, April 24

Sponsored by VERON of Nederland, the contest is open to all amateurs to help obtain their PACC award. Use all bands, 160 to 10 meters, CW or SSB, but no cross mode contacts. Categories: single or multi-operator and SWL.

EXCHANGE:

RS(T) and serial number from 001. PA/PI/PE stations will give province as well. Possible provinces are: GR, FR, DR, OV, GD, UT, YP, NH, ZH, ZL, NB, LB.

FREQUENCIES:

CW – 3525-3585, 7010-7040, 14025-14085, 21040-21100, 28050-28100.

SSB – 3650-3750, 7040-7100, 14150-14300, 21150-21300, 28200-28700.

SCORING:

Each PA/PI/PE QSO counts 1 point. Each station may be worked only once per band regardless of mode. Multiplier is number of provinces per band (max 12 per band x 6 bands = 72). Final score is then sum of QSO points times total multiplier. SWLs score same.

ENTRIES & AWARDS:

Logs must contain code group given by Dutch station and station worked with; usual score calculation is required. Please use a multiplier column and insert multiplier only first time worked. Include a signed statement that contest rules and regulations were observed. Certificates to each country, US and Canadian call district winners. Logs must be sent to: VERON Contest Manager, PAØDIN, Schoutstraat 15 Nymegen 6805, Netherlands, not later than June 15th.

Of last year's several hundred contestants, only 4 were from the US. Winners from stateside were: AC3ARK, AC1OPJ, and WB5IAL. How about a little more participation from the States?

H-22 CONTEST

Starts: 1500 GMT
Saturday, April 23
Ends: 1700 GMT
Sunday, April 24

Use all bands 160 to 10 meters, CW to CW or phone to phone.

EXCHANGE:

RS(T) and 3 digit serial number from 001; Swiss stations send abbreviation of their canton as well. Abbreviations for 22 cantons are: AG, AR, BE, BS, FR, GE, GL, GR, LU, NE, NW, SG, SH, SO, SZ, TG, TI, UR, VD, VS, ZG, ZH.

SCORING:

Each contact with an HB station counts 3 points; each station can be worked once per band regardless of mode. Multiplier is sum of Swiss cantons worked on each band, 22 max per band. Final score is total QSO points times total cantons worked on all bands.

ENTRIES & AWARDS:

Certificates to highest scorer in each country, US and Canadian call areas. Logs must be postmarked not later than 30 days after the contest and sent to: TM USKA, HB9AHA, im Moos, 5707 Seengen, Switzerland.

H-22 Award is available for working all 22 cantons on CW or phone (all one mode). Send QSLs to Walter Blattner HB9ALF, Post Box 450, CH 6601 Locarno, Switzerland.

CONNECTICUT QSO PARTY

Starts: 2100 GMT April 30
Ends: 0200 GMT May 2

Sponsored by the Candlewood Amateur Radio Association, all amateurs are invited to participate. Each station may be worked once on each band and mode. W1QI, the club station, will be operating CW on odd hours and SSB on even hours and counts for 5 QSOs (each band/mode). Novice QSOs count 2 points each.

EXCHANGE:

QSO number, RS(T), and ARRL section for out of state, and Conn county for Conn stations.

SCORING:

Out of state multiply QSO points times number of Conn counties worked (8 max). Conn stations multiply total number of QSO points by number of ARRL sections and provinces; DX stations count only as one additional section total.

FREQUENCIES:

CW — 40 kHz up from bottom of band.

SSB — 3925, 7250, 14300, 21375, 28540.

Novices — 3725, 7125, 21125, 28125.

ENTRIES & AWARDS:

Certificates to top scoring stations in each Conn county and each ARRL section or province. Logs must show category, date/time in GMT, calls, numbers, bands, QSO points, and claimed scores. A Worked All Conn Counties Certificate will be awarded for anyone working all 8 counties. Enclose a large SASE for results. Logs must be postmarked no later than June 1st to: Candlewood ARA, c/o Fred Porter W1VH, 169 Carmen Hill Road Nr. 2, New Milford, Conn. 06776.

THE 18th ALL ASIAN DX CONTEST

The purpose of this contest is to increase the activity of radio amateurs in Asia and to establish as many contacts as possible during the contest periods between Asian and non-Asian stations.

CONTEST PERIOD:

Phone: 30 hours from 1000 GMT June 18, 1977, to 1600 GMT June 19, 1977.

CW: 30 hours from 1000 GMT August 27, 1977, to 1600 GMT August 28, 1977.

BANDS:

The amateur bands to 30 MHz may be used.

ENTRY CLASSIFICATIONS:

Single operator, 19 MHz band (CW only); single operator, 3.5 MHz band; single operator, 7 MHz band; single operator , 14 MHz band; single operator, 21 MHz band; single operator, 28 MHz band; single operator, multi-band; multi-operator, multi-band.

POWER, TYPE OF EMISSION, AND FREQUENCIES:

Within the limits of own station's license.

CONTEST CALL:

For Asian stations: Phone — "CQ contest"; CW — "CQ test."

For non-Asian stations: Phone — "CQ Asia"; CW — "CQ AA."

EXCHANGE:

For OM stations: RS(T) report plus two figures denoting the operator's age.

For YL stations: RS(T) report plus two figures "00 (zero zero)."

RESTRICTIONS IN THE CONTEST:

No contact on cross band.

For the participants of single operator's entry: Never transmit two signals or more at the same time (only one signal may be used).

For the participants of multi-operator's entry: Never transmit two signals or more on each band at the same time (one signal per band may be used).

POINT AND MULTIPLIER:

For Asian stations: Point — A perfect contact with non-Asian station will count one point; Multiplier — The number of different countries in the world worked on each band (according to the DXCC countries list).

For non-Asian stations: Point — A perfect contact with Asian station will count one point; Multiplier — The number of different Asian prefixes worked on each band (according to the WPX rules).

About JD1 stations: JD1 stations on Ogasawara (Bonin and Volcano) Islands belong to Asia; JD1 stations on Minamitori Shima (Marcus) Island belong to Oceania.

Contacts among Asian stations and among non-Asian stations will count neither point nor multiplier.

Contacts with KA stations are not eligible. They are considered not amateur but military.

SCORING:

(The sum of the contact points on each band) X (The sum of the multipliers on each band).

INSTRUCTIONS ON THE SUMMARY AND LOG SHEET:

Use a separate sheet for each band. Please keep all times in GMT. Please fill up the blanks of "multiplier" by the countries or prefixes only the first time on each band.

AWARDS:

Both phone and CW certificates will be awarded to the highest scores of each entry in accordance with the number of the participants of each country:

If the number of participants is under 10, awarded only the first rank.

If the number of participants is 11 to 20, awarded the second rank.

If the number of participants is 21 to 30, awarded the third rank.

If the number of participants is 31 or more, awarded the fifth rank.

The highest scorer in each continent of the single operator, multi-band entry will get a medal and certificate by the Minister for Posts and Telecommunications of Japan.

The highest scorer of the multi-operator, multi-band entry in each continent will get a medal. In addition, certificates will be awarded to the highest scorer of each call area of the United States of America, in the entry of single operator, multi-band.

REPORTING:

The log and summary sheet must arrive together at JARL P.O. Box 377, Tokyo Central, Japan, on or before the following dates: Phone — September 30, 1977; CW — November 30, 1977.

DISQUALIFICATION:

Violation of the contest rules; false statement in the report; taking points from duplicate contacts on the same band in excess of 2% by the total.

ANNOUNCEMENT OF THE RESULT:

Phone — about February, 1978; CW — about April, 1978.

You may have contest results by enclosing one IRC and SAE.

1977 CAPE TOWN FESTIVAL AWARD

This award is available to all licensed amateurs. Contacts must be made during the period starting 2200 GMT April 1st and ending 2200 GMT April 30, 1977. All DX stations (non-ZS) are required to work ZS1CTF or ZS1CTM plus 2 other ZS1 stations. QSL cards are not required for the award. Submit an extract of your log, certified as being correct by either your local awards manager or two licensed amateurs. Any band, mode, or combination may be used. Closing date for applications is July 31, 1977. Certificates will be posted after this date only. The fee is $2.00 (USA). A special endorsement will be available for VHF contacts or may be applied for as an additional award. Applications should be addressed to: Derek Siegel ZS1DP, SARL CT Branch, PO Box 5100, Cape Town 8000, South Africa.

ALL VE/VO ON RTTY

Offered by the CARTG, VE3RTT, contacts must be 2-way RTTY only, any date. Award will be a certificate, numbering from one. There is no charge for the award, but the necessary QSLs are to accompany the request. They will be returned! An official of a RTTY group or society may inspect and send in a signed list of such QSL cards, including all pertinent information (in place of sending the actual QSLs). Send all requests to: The Canadian Amateur Radio Teletype Group VE3RTT, 85 Fifeshire Road, Willowdale, Ontario M2L 2G9, Canada.

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz.

OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz.

Mode 8: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

BE MY GUEST

visiting views from around the globe

from page 13

and the word "stroke," for portable and mobile. The English phonetics are widely used. Those who speak English obviously work twenty meters a lot. Europeans work all bands, except 6 meters. That is reserved for commercial and public service use. In Germany and Austria, there is no FCC. All communications are controlled by the Postal Department (heaven forbid it here!). The Postal Department not only monitors the ham bands, but it transmits on them, too. One afternoon in Frankfurt, I gave a call and received no immediate answer. Thirty seconds later, a booming voice came over the repeater saying, "Where are you located, W8WLQ?" He gave no ID. I gave my location in Frankfurt, and he said "Thank you." I heard the Germans buzzing about how the Post and Telegraph Director was on the repeater frequency. I was told by a ham in Vienna that their FCC monitors commercial stations for entertainment and hams for laughs.

Autopatch is forbidden in Germany and Austria. The telephone companies would lose the revenue. In Germany, most communications are run by the government. Ham licenses cost more in Germany and run for only a year. The cost of a visiting license in Germany is about $5.85; it is valid for three months and cannot be renewed. The ARRL will supply all the necessary information for applying for one. I would like to commend the German government, as they are quite helpful and expedient in processing licenses for visiting hams. When you receive your license, you are also supplied with a book of rules and regulations written in English.

If you travel by train in Germany and Austria, you will find them to be very efficient. They are always on time, and speed across the countryside at 50 to 100 miles per hour. They also use overhead wires in the city and suburban areas. If you are "train mobile" like I was, the overhead wires can make it difficult for you to hit the repeaters. The express trains only stop for one minute to load and unload passengers and mail, except at the border. At the border, you have six minutes to get off the train and exchange your currency. This is a must if you expect to use the diner. The currency and menus change in the diner, when you cross the border. First class is the only way to go (by train) in Europe. Only first class can sit in the diner. The compartments are large and air conditioned. The regular class cars are crowded, warm, and the seats are hard. You can work "train mobile" and it is fun. Contacts don't last too long, because of the speed of the train. The repeaters I worked from the train included Nurnburg, Regensburg, Passau, Linz, and Wels. For information purposes, the two crystal pairs I used while in Europe were 145.15 in, 145.75 out and 145.20 in, 145.80 out. One contact on the train that I had was in Austria and the train went right by the other station's house. I never did figure out which house it was, but he saw the train. A ¼ wave whip came in handy, both on the train and in the cities. It gave me a little extra rf when I needed it.

Vienna

Vienna is a beautiful and old city. Its people are friendly and fun-loving. The food and beer are excellent. The streetcar is the KING of transportation, but Mercedes taxis are plentiful and inexpensive. Vienna is my favorite city in Europe. I arrived four days earlier in Vienna than expected and this caused considerable trouble. Hotel rooms are at a premium in July and August and I found that renting a room without reservations would cost me up to $40 a day. This was out of the question with my budget. A taxi driver and a very pleasant lady passenger located a room for me near the inner city. I stayed at the Hotel-Pension Schneider for two days, during which time I was able to extend my previously made reservations for $6 a day.

Should you ever go to Vienna, I would like to recommend tours to the palaces, the inner city tour by horse and buggy, and a visit to the Prater amusement park. In the Prater, you will find, along with the circus atmosphere, outdoor restaurants, beer gardens, and a beautiful park. There is one beer garden in the Prater that holds over a thousand people, gallon glasses of beer, a floor show, and a German band. When the band isn't playing, the lights are turned down, and a waterfall with changing patterns and colored lights is exhibited. A little old lady passes through the crowd hawking white rosette radishes, alpine hats, and colorful flowers. One of the exciting landmarks in Vienna is the Dunube Tower. On top of the spire is a wonderful restaurant which gives a fine choice of gourmet food. While eating, you are overlooking the entire city of Vienna. At night, the lights below look like thousands of stars twinkling away in the distance. For those with a sweet tooth, the pastry shops are utopias.

When I arrived at the banhof, I had already been listening to the Vienna repeater. I didn't contact anyone on it till later. Once in my hotel room, I ordered a cold drink and "kerchunked" the repeater. I received a call from Peter OE1SP. He spoke English and I later found out he had spent two years or so in North Carolina. Peter was very helpful to me while I was in Vienna. Fred OE1BMA was another English-speaking ham with whom I had several contacts.

The repeater in Vienna was a simple one. It was an old taxi radio, with two vertical half wave antennas and no duplexer, which caused periodic trouble. Pigeon deposits have to be cleaned off of the antennas periodically to insure good radiation.

As my trip to Vienna was to attend a magic convention, my ham activities were confined to talking on the repeater. But Peter OE1SP invited me to a Liars Club one evening. The Viennese version of the coffee klatch took place in a beer garden. I believe the name to be The Green Lantern. It started at 1700 and was still going on at 1930, when I left. It was an informal get-together, with about 15 or 16 hams attending. Two or three of the hams spoke English and I tried to speak to the others in my broken German. My Austrian friends were impressed by some of the features on my Wilson HT. In Europe, the Ken and Standard are sold to the amateurs, not the Wilson. The Ken is somewhat smaller and does not have a separate microphone. It also lacks the auxiliary plug on top. Peter OE1SP told me the Wilson is approved for police use in Austria, whereas the Ken is not. I passed out some bicentennial QSL cards, drank a couple cups of espresso coffee, and caught a cab back to the hotel.

The next day I received a call on the repeater from another Viennese ham. I came back to him, and he asked that I only speak English. Sometime later, I learned that our QSO had been recorded and was to be played over an international short wave station. It would be beamed toward English-speaking countries. A very nice gesture on behalf of the Austrian government.

In Austria, there are about 1200 licensed amateurs: YLs get special calls, beginning with OE1Y. You must have a permit to buy radio equipment as well as a license. It is necessary to have a license to own a TV set or a regular radio. These are paid for by the year. I checked a radio shop in the center of Vienna, and found that the TS-520 in the window cost $995. I saw a couple of used pieces of Heath equipment and some two meter rigs. No place to look for bargain prices. Licenses are issued in Austria according to power: Class A – 25 Watts, Class B – 50 Watts, Class C – 100 Watts, and Class D – 250 Watts. Power is based on the plate dissipation of the final tubes. Non-code licenses are issued for 2 meter use. Licenses are issued to visiting amateurs at a cost of a $1 per month. You must have a license for each one of the 5 states in Austria in which you intend to operate your station. In Germany, one license applies for all of Germany. If you hear music being broadcast on ham radio in Austria, don't be alarmed; it's legal. It can be used for testing purposes. Repeater IDs are set at high speeds. This is requested by repeater club members, simply because it interferes with their conversation. There are few timers and they are extra long. This is because, once again, the members resent timers. Repeater dues in Vienna are $15 a year. The Vienna Liars Club meets Tuesday night, and the regular club meeting is Thursday night. Repeater frequencies for two meters are R10 to R19. R10 is 145.00 in and 145.600 out. The inputs start at 145.00 and go up every 25 kHz. Outputs are 600 kHz up. Simplex frequencies are 145.500, 145.525, 145.550, and 145.575. The 145.500 is the most commonly used one. For anyone wanting to apply for licenses for use overseas, or in any foreign country, it is best to write the ARRL. They will supply free all the latest requirements.

With all respect to the Austrians, the Gummi-Wurst (rubber sausage) is better described in the English language as a rubber duck. Hope you enjoyed the trip, and perhaps someday you will operate portable DL, OE, or even UA.

Micro Future

Purchases of computers and related products for home use will increase at an average 37.2% annual rate for the period 1976-1981, according to a recent study completed by Venture Development Corp., Wellesley MA. The study, "The Home Computer," represents over seven months of effort, during which time VDC queried hundreds of users, manufacturers, retail stores, and hobby groups.

The study reveals that not all computers used in the home are so-called "hobby computers," but that some are industrial single-board prototyping systems adapted to that purpose. This year, for example, 22.5% of the 24,164 computers purchased for home use will be supplied by such established "non-hobby" manufacturers as Intel, National Semiconductor, Texas Instruments, Intersil, and MOS Technology. Conversely, one third of the total computers

Calypso SOS

Sunday morning, January 30, 1977, several radio amateurs throughout the southern U.S. were galvanized into action by a distress message that eventually was found to be false. Before it became clear that the message was a hoax, many amateurs had become involved in relaying related traffic, and the U.S. Coast Guard had initiated an air search.

At about 9:45 am CDT, amateur radio station WB5LTP/MM2, aboard a vessel located about 100 miles south of New Orleans LA, reported he had copied the following message: "The motor vessel *The Calypso* is sinking off the Texas coast between Port O'Connor and Freeport, Texas. Located at about 96 degrees west, vessel is of 332 tons, 138 feet length, twin screw, radio call is FOAE." WB5LTP/MM2, the first radio amateur to retransmit this message on 7229 kHz, relayed its content to other amateurs.

The original message was transmitted by an unknown source on 7254 kHz, a frequency also assigned to the amateur radio service. It was received on the east coast, and also by an amateur operator in Colorado. In very short order the message was relayed to the Eighth Coast Guard Headquarters, New Orleans LA. On instructions from this office, an immediate air search was begun of the area. Advisories were transmitted to marine traffic to keep a sharp lookout for survivors or evidence of the disaster.

As a matter of fact, *The Calypso*, the famous oceanographic ship of Jacques Cousteau, was nowhere in the vicinity; it was safe and sound, thousands of miles away. Cousteau himself, however, was in the Gulf Coast area, diving to study and film underwater life in the vicinity of offshore oil drilling platforms.

Although many amateurs were chagrined at having been duped, Coast Guard reaction was one of satisfaction. Lt. L. H. Smith, Public Affairs Officer, U.S. Coast Guard Air Station, Corpus Christi, Texas, advised that this was the first time in his experience that a hoax distress message had originated on an amateur frequency. Lt. Smith remarked, "Had this situation been a true distress, the hams involved would have been commended for the detailed information passed to the Coast Guard."

Of the several Coast Guard officials contacted during and after this unfortunate incident, none criticized or blamed the radio amateurs involved. In fact, they expressed surprise at the accuracy and consistency of the message input arriving from stations located throughout the southern United States. One Coast Guard officer remarked, "I was so impressed with it all that I may just become an amateur radio operator myself!"

Hoodwinked?

"We are aware of no compelling reason why amateurs wishing to operate repeater, auxiliary, control, or remotely controlled stations should be continued to require the obtaining of Commission permission before beginning such operation, as they have in the past. For this reason, we propose to delete those provisions . . . requiring that licensees obtain prior approval of the Commission to operate a remotely controlled station and requiring that repeater stations, control stations, and auxiliary link stations be separately licensed. We would discontinue the issuance of station licenses with 'combined' station privileges: All amateur station licenses would convey authority to operate as repeater, control, auxiliary link, and remotely controlled stations now operate." That's a quote from the Notice of Proposed Rule Making, dated January 6, 1977.

Editorials should be short and to the point . . . so here goes. The radio amateur is proud of his hobby and his ability to regulate himself. Here's hoping the Federal Communications Commission isn't being "hoodwinked" into believing it can shirk some of its own responsibility, that of helping us help ourselves. Repeater councils have been and are doing an excellent job of coordinating. It is still relatively simple to obtain repeater authorization, when and where it is needed. Let us not deregulate what might need more regulation in the future. Instead, let us demonstrate to prospective hams that *we can operate under an existing set of responsible regulations.*

Rig Service

1. Approach the ailing equipment in a confident manner. This will give the instrument the (often mistaken) idea that you know something. This will also impress anyone who happens to be looking, and if the equipment should suddenly begin working, you will be credited with the repair. If this step fails, proceed to Step 2.

2. Wave the *Handbook* at the instrument. This will make the equipment assume that you are at least somewhat familiar with the sources of knowledge. Should this step fail, proceed to 3.

3. In a forcible manner, recite Ohm's Law to the instrument. (Before taking this step, refer to some reliable handbook and be sure of your knowledge of Ohm's Law.) This will prove to the equipment beyond a shadow of a doubt that you do know something. This is a drastic step and should be attempted only after the first two steps.

4. Jar the equipment slightly. This may require anything from a three to a six foot drop, preferably on a concrete floor. However, you must be careful with this step because, while jarring is an approved method of repair, we must not mar the floor. Again, this is a drastic step, but if it fails, there is nothing to do but to move to step 5.

5. Add a tube, resistor, or capacitor. This will prove to the instrument that you are familiar with instrument design. Also, this step will give the piece of equipment an added load to carry and will thereby increase your advantage. If these five steps fail to work, you must proceed to the most drastic step of all. Seldom needed, it is to be used only as a last resort!

6. THINK.

produced this year by MITS, Inc. and IMS Manufacturing Corp., currently the two largest hobby computer suppliers, will be sold for non-home use, although the remaining two-thirds will acount for 40.7% of the home mainframe market.

The VDC study analyzed hobbyists and their applications, finding that less than one-half of all self-described computer hobbyists own computers, and that over 70% of owners use their systems for games. System utilization for this application is currently 32.8%.

VDC's analysis of distribution patterns revealed that 61.6% of home/hobby computer sales in 1977 will be made by computer stores. Over the 1976-1981 period, computer store sales of computers for home use will increase at an average 47.8% annual rate in terms of units, and at an average 46.3% rate in terms of revenues. Purchases by commercial users will account for an increasing percentage of total retail sales over this period.

Revenues from home/hobby computer submarkets (main memory, peripherals, software, miscellaneous products) will increase less rapidly than mainframe revenues between 1976 and 1981, with mainframe revenues showing an average annual increase of 42.5%, and submarket revenues growing at an average 35.1% annual rate. Software will represent the fastest-growing submarket, averaging 81%/year growth through 1981. Among the standard peripherals purchased for use by hobbyists, floppy disks will exhibit fastest growth, rising 63% annually in terms of units.

times. A controversy arose early in February after a New Hampshire motorist was ticketed and fined by a Massachusetts State Trooper. A Boston area legislator is mounting a drive to have the bill repealed. Massachusetts is well known for a large number of strange laws that have never been taken off the books. Keeping both hands on the wheel at all times makes it difficult to do things like turning on headlights or even shifting.

High power rf energy at 13.56 MHz is the basis of a new type of cancer therapy that is achieving a high degree of success at several hospitals throughout the United States. The therapy is based on the fact that blood flow through a cancer area is drastically decreased because the explosive growth of a tumor pinches the vessels shut.

Doctors use an rf generator with an output of 1000 Watts at 13.56 MHz, the lowest frequency approved for medical use by the FCC. The rf is transmitted from an amplifier to an impedance matching circuit via coaxial cable that is connected to electrodes in the tumor area.

When the rf is applied to the electrodes, immediate heating of tissue takes place. In normal non-cancerous tissue, the normal flow of blood cools the area so that no damage is done. However, with the constricted blood vessels of a cancer tumor limiting blood flow, that area is heated above the temperature at which the cancer cells are destroyed.

Of 21 patients treated so far, all were cured by the technique. Doctors are encouraged and plan to use the rf treatment mainly in areas where it is difficult or impossible to operate. *Reprinted from the* Journal of the American Medical Association.

What is the status of the two rf interference bills which are pending before Congress? According to Senator Barry Goldwater K7UGA, they may be in trouble. In a letter to an unidentified member of the Arizona Repeater Association, Goldwater writes:

"To put it as bluntly to you as I can, so you can pass it on to your readers, that fabulous affair we call politics has gotten into the matter of the two bills you have written to me about.

"The electronics industry in this country is a very large one and it isn't about to want to spend another dollar or two to make a receiver or a TV set immune to other frequencies. The industry has been working hard on the committees and I can assure you that I will continue to work hard on this. I really think that as the people begin to understand it as organized labor already has, we are going to get this passed either this year or probably next year." *Tnx to* Arizona Squelch Tail.

Attorneys for Offshore Navigation Incorporated, a New Orleans based radionavigation service with a subsidiary in Canada, have informed the Canadian Department of Communications of their disagreement with a WARC proposal by the Canadian Radio Relay League that 420-450 MHz be exclusively allocated to amateur service.

In the letter, the attorneys confirm that up to the present time, radiolocation operations in the band have been minimal. They add that the situation is in the process of change and that they anticipate the band will be heavily used for radiolocation in the near future due to comprehensive development of new equipment for use in this band. The equipment would replace current SHORAN equipment, which is 20-30 years old and of tube design. They point out that development work has been in progress for more than two years, with a prototype system under test for over a year. Delivery of additional systems is planned for the near future.

In conclusion, the letter urges the Department to maintain the provision for radiolocation in the 420-450 MHz band. There was no immediate comment from the Canadian Radio Relay League.

A letter from the Canadian Radio Technical Planning Board to John Van Der Ryd VE3CYC has taken issue with Van Der Ryd's letter on page 9 of the January issue of *73*. In the letter, Van Der Ryd claimed that at a meeting last fall between the Canadian Radio Television Planning Board and the DOC in Ottawa, a discussion to rearrange frequencies between 406 and 960 MHz included a suggestion to take the 440-450 MHz band away from amateurs.

Bud Punchard VE3UD, Chairman of the ad hoc committee on the band, replied that the committee has recommended that amateur bands in that band remain unchanged. Punchard added that the group is working hard to save bands for amateur use.

The Amateur Radio News Service has announced the rules for its 1977 annual contest. The contest is aimed at promoting amateur radio journalism in club publications of various sizes. Club bulletin and newsletter editors are urged to send three different issues of their publications from the year 1976 to the three judges listed below. The deadline is April 15th, according to ARNS spokesman Norm Monro. There are six categories in the compeition: Class A (for publications subsidized in part by outside interests), and Class B (for publications produced solely through the resources of a club or organization), each further broken down into three divisions, depending on circulation, in multiples of 50 or more. Three copies must be mailed to each judge: Norm Monro K4FRY, 215 Brindly St., Gadsden AL 35901; Phil Sager WB4FDT, 3877 N. Abingdon, Arlington VA 22207; and Lee Knirko W9MOL, 222 S. Riverside Plaze #2400, Chicago IL 60606. Each entry must be accompanied by an official class of entry, the name and address of the editor, and the publication's average monthly readership.

According to the *West Coast DX Bulletin*, it appears that Yugoslavia has moved to give their amateurs privileges in the 160 meter band. YU1PCF was worked on the band recently and another Yugoslavian amateur, YU3EY, is also active. First reports are that their 160 band is only 10 kHz wide with activity recently heard on 1830 kHz.

The phenomenal success and growth of the "Sidewinders on Two," a two meter SSB group headquartered in Fort Worth TX, has created a money problem. In the past, an annual $2.00 fee was sufficient to mail club bulletins to all members. The February bulletin of the group, however, lists 366 members, making it necessary to charge for postage. Now a $5.00 fee will cover both membership and a subscription to the bulletin. Those who wish membership only can still join for S2.00.

More information is available from Sidewinders on Two, 1704 Glenn Drive, Fort Worth TX 76131.

Western Airlines Captain Carl Smith WØBWJ earned a "good guy" award from the mayor of Honolulu HI recently after making a perfect two-point landing of his 707 at the Honolulu airport in January. The landing was made necessary after the nose gear of the airplane failed to extend after repeated attempts. In the true tradition of amateur radio operators, Smith handled the situation coolly and professionally and said it was "not an adrenalin situation." He refused an offer of foam being spread on the runway and landed the big jet perfectly on two sets of wheels, taxiing for some distance before dropping the nose. No one was injured.

He Made the Best of an Emergency Situation

Safe Landing Earns Pilot a 'Good Guy' Award

Over the years, the Collins KWM-2 and KWM-2A single sideband transceivers have undergone a number of modifications, some of which were made during the period the unit was used in military service.

Available through Military Affiliated Radio Service (MARS) libraries, and the Government Printing Office, is an Air Force Technical Manual that lists over 50 modifications to the KWM-2/KWM-2A, along with expanded, fold-out diagrams of the circuitry, which are a great improvement over the amateur-style instruction manual.

The title of this technical manual (TO-31 R2-4-183-3) is: *KWM-2A Transceiver*. It also covers changes to the 30L-1 and 30S-1 rf amplifiers.

A second technical manual of interest to KWM-2/KWM-2A owners is TO-31R2-4-183-2, entitled *Technical Manual (Service) KWM-2A Transceiver*. It also covers the previously mentioned amplifiers. This publication provides detailed alignment instructions for the transceiver and linear amplifiers. *Thanks to* Parking Ticket, *bulletin of The Plano Amateur Radio Klub, Inc., PO Box 435, Plano TX.*

Previously unpublished papers on all technical subjects relating to amateur radio are invited to be submitted for the 1977 ARRL Technical Symposium. The event will be held in September in Falls Church VA under the management of the Amateur Radio Research and Development Corporation and is sponsored by the Northern Virginia Amateur Radio Council.

Areas of interest include propagation, antennas, transmitting and receiving equipment, amateur applications of microprocessors, design and construction techniques, station and shop design, HF techniques, VHF/UHF repeaters, ATV, RTTY, space communications, microwave, and any other topic of technical interest to amateurs.

Prospective contributors should forward an informal summary, along with a photo and one page biographical sketch, by July 15. Manuscripts are due by August 15. For more information write Paul Rinaldo W4RI, 1524 Springvale Ave., McLean VA 22101.

While you're about it, how about submitting the article to *73*? That way you can get paid for your effort.

Australia may soon have a CB problem of its own. At present, there is no licensing system for CB radios in that country, but an increasing number being brought in from the United States are beginning to create interference problems "down under." Some estimates put the number of radios currently being used at near the quarter-million mark. Although not illegal at the moment, it is becoming clear to government authorities that they will soon have to develop legislation to regulate the units. They are currently studying alternatives. The Wireless Institute of Australia, the

country's amateur organization, has offered the government help and expressed concern that possible legislation regarding CB will adversely affect the state of amateur radio in Australia.

OSCAR 6 continues to show signs of deterioration. When launched in October, 1972, the amateur satellite had an expected life of one year. It's been going strong until recently when telemetry data showed that one of the 18 cells had failed, and there were strong indications that a second was about to. OSCAR 6 passed through the period of highest temperature at the end of January and beginning of February. During this period, the satellite is in sunlight 100% of the time and temperatures inside rise drastically. AMSAT president Perry Klein told *73* that this high temperature period is detrimental to the batteries. Both OSCAR 6 and OSCAR 7 pass through full sunlight periods twice a year. Klein added that AMSAT expects to shut down OSCAR 6 when the A-O-D satellite is launched later this year. That is, of course, if OSCAR 6 lasts that long.

Meanwhile, OSCAR 7 was continuing to have problems with overcharging of the batteries and was alternating between Mode B and Mode C on all orbits. It was theorized that a bad solar aspect angle with the sun hitting the satellite on the top only might be responsible for the problem.

On the lighter side, the International Repeater Group in New Brunswick can be thanked for the following compilation of a few categories of the infamous "thumpers":

Early Morning Thumpers: The first thing they do each morning is check to make sure the repeater is on. They usually get up between 6:15 and 7:15.

Late Night Thumpers: They give the repeater a little thump before going to bed.

73 and 88 Thumpers: After a QSO, they always have to thump the repeater a few times as a friendly way of saying goodbye.

Repeater Checker Thumpers: On an irregular basis, all repeaters in the area get a thump to find out if they are on the air.

Casual Thumpers: They check to make sure the repeater is still on the air at various times throughout the day.

Rapid Fire Thumpers: Those who like to see how many times they can push their mike button in three seconds.

Guess Who Thumpers: They always return a thump to the Casual Thumper, but don't like to give their call.

If you're looking for another certificate, why not try the Capitol Hill Amateur Radio Society? W3USS runs a kW on SSB and CW from the basement of the Old Senate Office Building in Washington. Antennas range from a vertical to a three element tri-bander up 120 feet. As Pete WA3KSQ put it, "For those in a hurry, it takes only three minutes to travel from our QTH to the Senate floor."

This year's observance of Armed Forces Day, scheduled for Saturday, May 21, marks the 28th anniversary of this annual event.

A featured highlight of the day will be the traditional military to amateur communications tests. The proceedings include operations in CW, SSB, RTTY, and SSTV.

Certificates will be awarded to amateurs who accurately copy the Armed Forces Day message from the Secretary of Defense, Harold Brown. The message will be transmitted in both CW and RTTY.

The military to amateur crossband operations will be conducted from 1300 UCT on May 21 to 0245 UCT on May 22. Military stations NPL, NMH, NAM, NPG, WAR, and AIR will transmit on military frequencies and listen for amateur stations transmitting in portions of the amateur band. The operators at the military stations will specify which portions they are listening to.

73 will publish a complete list of the frequencies in next month's issue.

Want a two letter callsign? April 1 will be the date on which you can apply if you received your Extra ticket between July 1, 1974, and July 1, 1976. If you received the Extra after July 1, 1976, you can apply on July 1, 1977 or later. If you had an Extra before July 1, 1974, you are eligible to apply immediately.

The Dallas TX Amateur Radio Club reports that thefts of two-way radio equipment in the Dallas area declined at the end of 1976. During the month of December, 565 radios were reported stolen to the Dallas Police Department, a low for the year. The total for the year was a staggering 10,635. Several Dallas Police spokesmen expressed the opinion that the trend has gone full circle and thieves might go back to hubcaps and mag wheels. With 40 channel CB rigs and the increasing use of mobile 2 meter equipment, what will happen remains to be seen.

In an effort to improve their signal to the western United States, W1AW in Newington CT has been conducting tests with a variety of antennas. Comparisons were made between a 4 element 20 meter yagi and a rhombic. Reports from Los Angeles favored the rhombic, although stations 20 degrees off heading reported the yagi as superior. Comparisons between the W1AW signal and other amateurs in the Hartford CT area were also made. In some cases, signals were 10 to 12 dB in favor of the other stations.

It was decided to build a new array with stacked 4 element 20 meter beams at 60 and 120 feet, and a 3 element 40 meter beam at 90 feet. The project is funded by a bequest from silent key W8FX, a longtime Michigan S.C.M. The array will bear a plaque in his memory.

As part of a federally funded project, a study team at Cornell University recently spent time monitoring conversations on the CB channels. According to their conclusions, almost 50% of the conversations were discussions about the locations of the parties involved, 20% were discussions of equipment and technical aspects, and less than 5% were requests for information, "smokey reports," and traffic directions.

The study showed that 75% of the communications were directed specifically at another party, although in over 50% of the cases, the operator was unable to find the party that he was seeking.

They found that 50% of the traffic occurred on Fridays and Saturdays, with the peak time between 5 and 6.

In conclusion, the study team called CB a "wireless party line used primarily as a way of making friends and maintaining a community network."

EDITORIAL BY WAYNE GREEN

from page 4

stopping at either 13 or 20 words per, but heading for them thar hills. Some preliminary experiments with high speed code indicate that it may not be much more difficult to master than slow speed code . . . indeed, it may not take much longer than learning slow speed code . . . once instructors are able to get over using the graduated teaching method.

Despite the example of more and more code classes starting students out at 13 words per minute right from the beginning and making the goal in less than half the time required by the old (ARRL) system, all of the code learning systems on the market today (except the *73* tapes) go the same old route . . . and that includes the just released ARRL tapes which teach 5, 7½, 10 and 13 per . . . for those who want to take the time to learn four different code speeds.

The next step is to try starting people out at copying code at 50 words per minute, right from the start. The whole idea of copying code is to train the brain to translate the sound patterns on a subconscious level, thus getting around the slowness of the computer system on the conscious level. The code translation on the conscious level bogs down at around ten words per minute . . . the famed "plateau." It is only after this plateau has been reached in the normal code learning system that the whole business is turned over to the subconscious mind for deciphering.

When you hear di-dah and then say, *"hmmm, that's A," you're looking it* up in memory and the circuits involved are many and relatively slow. When you hear di-dah and your fingers write or type "A" before you can say it, then you're working on a subconscious level and headed for speed.

Let's get some hams who would like to try for 50 per and start them out with the dots and dashes at that speed . . . crank up the keyboard or bug and send individual letters well spaced at first . . . then close up the spacing as you go. You'll quickly be able to tell the difference between even the most similar of letters such as 1 and J. Let me know how you do.

New Products

YAESU FT-221R TWO METER ALL MODE TRANSCEIVER

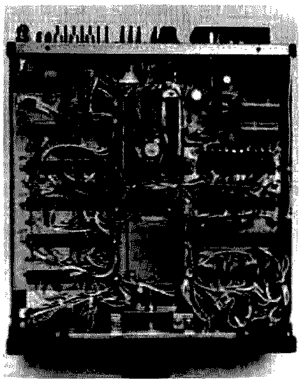
The 2 meter operators who have confined their VHF activities to FM are in for a surprise: The spectrum between 144 and 146 MHz is alive with SSB activity, but without the problems of QRM, jamming, and the general disorders associated with low band sideband operation. In order to join the fun of 2m SSB, a suitable transceiver is required, and the Yaesu people provide a perfect rig – the FT-221R. This all mode transceiver provides every feature required to fully exercise the 2m band.

The transceiver is VFO controlled, and main dial accuracy is maintained by dividing the 4 MHz 2m band into eight 500 kHz segments, with each segment being selected by a rotary switch. Main dial resolution is 1 kHz. If crystal control is desired, the operator has a choice of eleven crystal positions controlled by a front panel switch resulting in 88 crystal channels. The rig also has a standard built-in calibrator that can be used to perfectly set the main dial. This is accomplished by turning on the calibrator and adjusting the main tuning knob while locking the VFO with a button located by the dial. A signal strength meter doubles as a center scale discriminator meter when receiving FM. The meter also reflects relative output power when transmitting. The operator also has control over rf gain, squelch, audio and microphone gain, VOX gain, and repeater control via front panel controls. Standard and reverse repeater offsets are provided, as well as an operator selected offset. The additional offset is generated by an internal crystal, provided by the user. A mode control selects upper or lower sideband operation, as well as FM, AM, and CW. And finally, a clarifier control is provided for the SSB operator. CW sidetone, noise blanker, and repeater tone burst functions are standard features, making the FT-221R a totally versatile package. The radio can operate on either 12 volt dc or ac line. The power transformer is tapped for those who have non-standard line voltage.

Operating the FT-221R is a joy. I spent an entire weekend operating the transceiver in the rf-burdened New York City area, and never experienced any problems relating to overload or intermodulation. I started my day by making a few basic tests on the transceiver.

I checked the FM power output with a Bird 43 wattmeter, and found the transceiver was delivering 22 Watts into the line. Sideband PEP output was about the same, as was CW. The AM output was four Watts. (Yaesu rates the FT-221R at a conservative 14 Watts on FM.) I have often wondered about the accuracy of VFO tuned rigs on VHF. A frequency counter check of the main dial resolved the question, as accuracy was within 100 cycles at all settings. Drift was undetectable. My first operating test consisted of a rag chew on FM simplex with friends. Perfect tuning is accomplished by using the center scale discriminator meter, and no off-frequency problems were encountered. The receiver is superb, and the rf gain control can be used with the squelch function to select the group of stations desired. I live on a hill, and undesired distant FM stations have always been a problem. Not so with the Yaesu; the rf control took care of that situation. I tried the local repeaters next and encountered no tuning or operating problems or peculiarities. The microphone gain control allows considerable latitude in deviation, a necessary feature when using city repeaters with narrow audio bandpass characteristics.

The time was finally right for SSB. Not knowing the two meter calling frequency, I tuned around "below" 146 MHz until the familiar SSB sound was heard. A touch of the clarifier, and perfect audio resulted. SSB tuning is sure and solid, and there is no drift once the signal is tuned. Breaking into the QSO resulted in an hour long round table with four others on SSB, and two of the stations were well outside my normal FM range. Encouraging signal and quality reports were received, so I decided to call CQ (it is acceptable on 2m SSB!) on the national SSB calling frequency of 145.025 MHz. I talked to several other SSB stations on both sidebands, and noted that there is no shift when switching between the upper and lower sideband. The 221R was rock solid throughout the session, and nothing but favorable reports were received. The VOX functioned well, and I found operating 2m SSB was much like a late evening crosstown QSO on 20m when the band is out. No QRM, no problems. It was also obvious that 2m SSB activity is growing, as virtually every CQ resulted in a contact.



Underside of the FT-221R. Most of the circuitry is contained on easily removable cards that slide into the visible edge connectors.

The FT-221R is bound to excite the OSCAR satellite operators. Being VFO controlled, the transceiver can easily be operated in the OSCAR 7 Mode A transmit region, or the Mode B receive segment. One of the editors at *73* is an OSCAR enthusiast, and his first test of the Yaesu was to fire up during the first available OSCAR 6 pass. He was immediately rewarded with a contact from Argentina, with good signal and quality reports. The FT-221R has sufficient power to work the satellites with simple antenna systems. The operator at *73* used a Ringo antenna tuned to the high end of 2 meters with good results on both OSCAR 6 and OSCAR 7.

Everything considered, the Yaesu FT-221R is a pleasure to operate. There are enough controls and options to please the most demanding operator, yet one does not get lost when operating. There are no tuning or loading controls. The amplifier delivers full power from band edge to band edge, and there is no obvious evidence of spurious output (immediately detectable in the New York area, as there is a repeater or public service outlet on almost every VHF channel). The receiver does not appear to "peak" anywhere on the band, and is immune to the intermodulation headaches known by all city operators. Single sideband operation, which is the 221R's forte, is superb, and is guaranteed to open a new frontier for those 2m operators who are tired of FM and repeaters. The Yaesu FT-221R is priced at $629. *Yaesu Electronics Corp., 15954 Downey Ave., Box 498, Paramount CA 90723.*

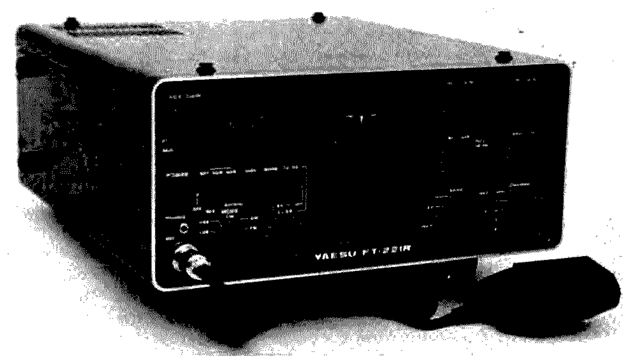
MONITOR TUNER 160-10 MAT AND SUPER SUPER TUNER

Having moved into a new house just before the first snows of winter set in on New Hampshire, I did not have time to erect all the antennas that I wanted. In fact, the only antenna I could get into the air was one of the more common 75 and 40 meter multiband dipoles which are available commercially. This 66 foot antenna works fine in the 75 meter band (and has a pretty flat swr curve throughout the 40 meter band), but it was completely unsuitable for any of the other bands. This is quite a devastating problem for the avowed DXer, especially during the international DX contests when operation on other bands is definitely desired.

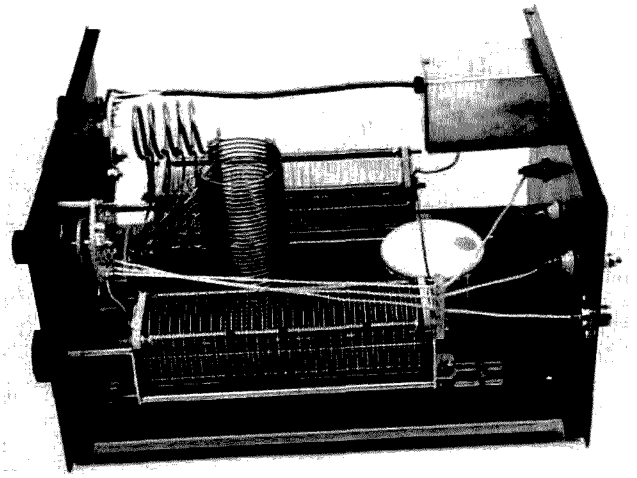
Of course, what I needed was an antenna tuner – and a good one at that. Knowing that eventually I was going to increase my station power from the current 180 Watts PEP to 2,000 Watts PEP, I started looking for a tuner that could handle the legal limit. Having had some prior experience with equipment by the Dentron Radio Co., I chose their Model 160-10 MAT Monitor tuner. Besides being able to handle upwards of 3 kilowatts,



The Yaesu FT-221R. Note double-sided tuning scale and 8 position bandswitch that allow accurate VFO tuning.

The Dentron Radio Monitor Tuner – basically the same unit as the Super Super Tuner, but with an swr/power meter built in.

this tuner has a built-in rf power meter which shows both forward and reflected power at the flick of a switch, making tune-up a snap. It also features an easily accessible front panel switch which permits you to select either the coax, balanced or random wire terminals on the back of the tuner. You therefore can have three antennas or a dummy load connected to the tuner at one time and be able to select any one without the need to disconnect the others. I tried this with a 50 foot wire which ran from my bedroom window to a nearby tree – it loaded perfectly on 15 meters while hooked to the random wire terminal. There was no need to disconnect my multiband from the coax connector while this test was being made. By the way, the multiband worked out fine on all bands through 10 meters, and I even managed to pick up a few new countries on both 15 and 10 during the February DX contest.



Guts view of the Monitor Tuner by Dentron. Round plastic device on the right is a balun.

The Monitor tuner also comes without the rf power meter (in which case it is called the Super Super Tuner). For those of you who are lucky enough to have an accurate separate meter, this is a good deal. The tuner is well named. The bridge and meter unit is also available as a separate unit for $99.50.

The construction of the unit is very sturdy, and the coil and rugged capacitors were chosen to be well within the power range of the unit. The case measures 9" x 13" x 16" and fits nicely on any operating table. The price is also right, with the metered unit costing $299.50 and the unmetered version $229.50. *Dentron Radio Company, Incorporated, 2100 Enterprise Parkway, Twinsburg OH 44087.*

73 TESTS THE COMMUNICATIONS RECEIVERS

The 1979 WARC conference has many of us thinking about the future of the ham bands. As we reported back in February, and have updated elsewhere in this issue of 73, amateur radio is only one of more than a dozen services vying for spectrum space. And compared to amateur allocations, frequencies set aside for international broadcasting (about 2 MHz not counting the "tropical" SW bands) are much more important to the majority of WARC delegates.

Foreign broadcasting is closely tied to foreign governments, in most cases controlled *by foreign governments. It is a highly political business, employing great numbers of personnel (over 3 thousand in the Voice of America alone). Radio Liberty and Radio Free Europe, until recently, were secretly funded by the CIA. That should be a clue to the political stakes involved.*

US government figures compiled five years ago showed nearly 7 thousand hours of programming per week *from the communist bloc alone! That's enough programming to keep about 45 transmitters going continuously. The western bloc broadcasts about twice as much on the SW bands, over 12,500 hours per week, according to a BBC survey. Russian broadcasters, considered separately, are beaming programming in 84 different languages (by US figures), an expensive proposition at the least. Even the smaller countries are making substantial investments in foreign language transmissions, such as Cuba with 8 languages, and Mongolia with 4.*

Amateurs active on 40 and 80 meters are well aware of the power and bandwidth the SW broadcasters use, and the intensity of their activity. Stations from every corner of the world can be received with simple whip antennas, and many of us found our way into ham radio by listening to them.

Many hams are still SWLing and, by recent reports, it appears the hobby is headed for a revival on the heels of what's been called "the personal communications boom." One report has it that there are so many SWLs active in Japan that some broadcasters are limiting or ending QSL services. One country's SW service was saved from shutdown (an austerity move) by hundreds of complaints from overseas listeners!

Nearly all SW broadcasting is AM, but there are mounting arguments to switch to SSB while retaining the carrier, thus preserving space in the already overcrowded bands. The broadcasters themselves don't like the idea for a variety of reasons (mostly economic), but SSB on SW broadcasts seems to only be a matter of time.

Recognizing the growing interest in SWLing (and scores of letters from 73 readers wondering what's available nowadays in general coverage communications receivers), we begin this month a series of reviews intended to cover the major gear available. Our premise is that many amateurs are now considering a reasonably priced general coverage receiver, not only for SWLing, but as a standby for their station receivers. There are several ways you can use a standby – for spotting on other bands during a contest, for example, or with VHF-UHF converters to keep your HF station separate, and so on. On top of the amateur uses, there is, of course, the benefit of SWLing itself.

SWLing can be much more than listening to foreign broadcast outlets – there are thousands of point-to-point communications to intercept, ranging from aircraft control circuits to foreign embassies communicating with home. A book is even available on "secret" frequencies, called the Confidential Frequency List, *by Robert Grove and published by Gilfer Associates, Park Ridge NJ. Everything from foreign embassies to CIA frequencies (those registered with the ITU) is listed in 34 different sections.*

Microprocessor hobbyists are into SWLing as well, using their uPs for deciphering high speed RTTY broadcasts. (Several articles on the subject are coming up in future issues of 73.)

There is much more, of course, to be said about SWLing, but hopefully we've whet your appetites with this brief introduction. So here's part one of 73's survey of general coverage SW receivers.

THE DRAKE SSR-1 COMMUNICATIONS RECEIVER

My first receiver (save the crystal set I built out of a science lab kit) was a GE nine transistor portable. It covered only 4 to 12 MHz (plus the AM broadcast band) without the benefit of much more than a volume and tuning control. My antenna was a bizarre concoction of wire scraps that eventually wound around the house, up into the attic, and out to a tomato plant stake in my mother's vegetable garden. With each new find of scrap wire, the random antenna grew in length.

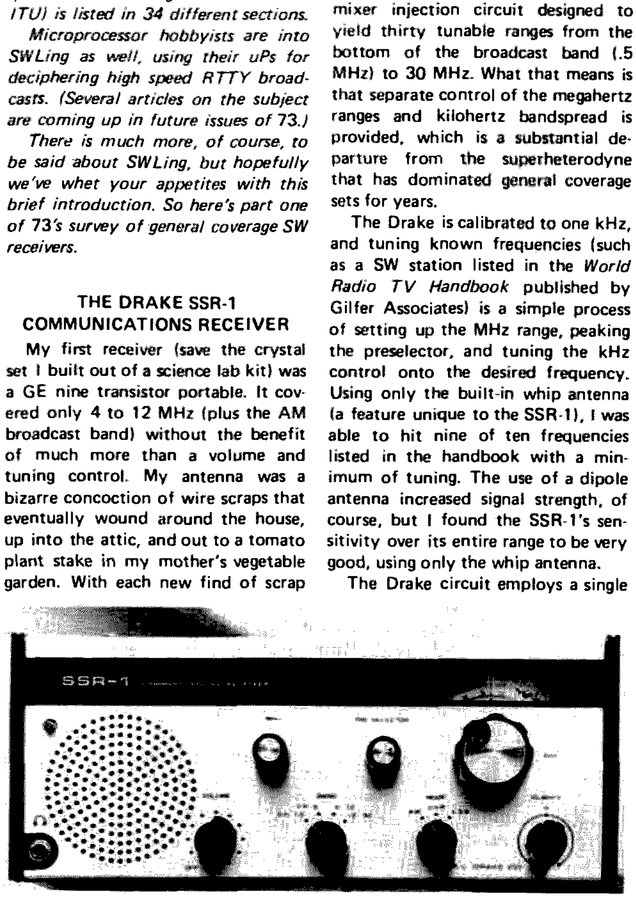
Fifteen years have passed, and a lot has happened with communications receivers. First of all, Dr. T. L. Wadley designed the so-called Wadley loop, first popularized in the British Racal line of receivers. The Wadley loop reached a worldwide audience through the South African manufacture of Barlow-Wadley receivers, and they were dominant among SW enthusiasts for decades.

More recent developments in PLL circuitry and the apparently booming interest in SWLing have brought a series of medium priced general coverage receivers, primarily from Japan. The Drake SSR-1 is imported by Drake from Japan and well represents the new generation in SW sets.

The Drake uses a synthesized first mixer injection circuit designed to yield thirty tunable ranges from the bottom of the broadcast band (.5 MHz) to 30 MHz. What that means is that separate control of the megahertz ranges and kilohertz bandspread is provided, which is a substantial departure from the superheterodyne that has dominated general coverage sets for years.

The Drake is calibrated to one kHz, and tuning known frequencies (such as a SW station listed in the *World Radio TV Handbook* published by Gilfer Associates) is a simple process of setting up the MHz range, peaking the preselector, and tuning the kHz control onto the desired frequency. Using only the built-in whip antenna (a feature unique to the SSR-1), I was able to hit nine of ten frequencies listed in the handbook with a minimum of tuning. The use of a dipole antenna increased signal strength, of course, but I found the SSR-1's sensitivity over its entire range to be very good, using only the whip antenna.

The Drake circuit employs a single



The Drake SSR-1 receiver, with a simple layout and 500 kHz through 30 MHz coverage.

10 MHz crystal oscillator, so unmodulated signals will appear at multiples of 1 MHz. Although this could be eliminated in circuit design, Drake says it would push the cost of the SSR-1 right out of its price class. Another side effect is small birdies, which are easily tuned out with the MHz control. Peaking a signal for maximum strength with the preselector, kilohertz, and megahertz controls will eliminate the birdies completely. They can, in fact, be used as a tuning aid, since eliminating the birdie peaks the receiver on frequency. In a month and a half of operation, I never found the birdies objectionable, and as for the 1 MHz unmodulated signals, they were very helpful as calibration markers. (Tuning WWV at 10 MHz, I found the SSR-1 within 100 Hertz.) One final point on this: Using other synthesized receivers in this price class shows that all of them have their share of birdies and 1 MHz markers. I never found them objectionable and they did not interfere with reception to a degree justifying the 2 or 3 hundred dollars more investment necessary to eliminate them.

The SSR-1 is completely solid state, with a built-in battery pack which requires 8 type D flashlight batteries. The dial lights are disabled when using the dc supply, which automatically switches on if ac is disconnected or interrupted. A push-button switch on the SSR-1's front panel is used to momentarily operate the panel lights when using dc power. Another feature is a 12 V dc power plug on the back apron which, when used with an accessory cable, allows use of the radio in an automobile or boat. Power consumption was measured at just under 100 mA at 12 V dc. The ac supply can be switched between 117 V and 240 V through a tapped transformer.

The Drake receives AM, CW, and SSB signals quite well, with good stability and audio response. The SSR-1 has separate detectors for AM and SSB, another feature unique to the Drake set. On AM it's a diode detector and 5.5 kHz filter, while on SSB-CW Drake uses a product detector and 3 kHz filter. Cross modulation noted on extremely loud signals was easily eliminated by switching in the 20 dB pad. Another feature exclusive in its class with the Drake is a ±3 kHz clarifier. The clarify control makes SSB and CW reception precise, since it acts as a fine tune control. In addition, heterodynes can be reduced in the AM mode with the clarifier.

I would not hesitate to recommend the SSR-1 as a standby receiver for CW and SSB reception in the ham shack. Muting provisions are included through an RCA type connector on the rear apron, and through a signal splitter, the SSR-1 served well as a spotting receiver during a recent DX contest. I've also used it with my standby transmitter for CW work with good results. I did find an audio filter (MFJ type CWF-2BX) very helpful in getting the passband down below the Drake's 3 kHz CW-SSB filter. The front panel 8 Ohm headphone jack came in handy there, plus I found the receiver had more than enough audio output to drive the outboard filter and headphones. (The SSR-1 is equipped with a front panel speaker.)

The Drake is the smallest general coverage receiver in its class — 13" wide by 11" deep by 5½" high. It weighs 14 pounds less the battery pack, and comes with accessory mounting feet to allow installation with the front panel sloped slightly upwards.

Among the accessories Drake offers for the SSR-1 are matching headphones model HS-1, dc power cord, and an antenna kit for the SWL bands. List price on the SSR-1 is $350, but company officials say dealers are discounting them down to the $279-299 price class. (Check with your local Drake dealer for details.)

In conclusion, the Drake SSR-1 is a compact, go-anywhere general coverage receiver with excellent stability, and sensitivity enough to receive signals from the broadcast band through 10 meters using only the supplied telescoping whip antenna. The SSR-1 allows precise tuning, directly from frequency tables, on the SW bands to within a few kHz. It is in an attractive, self-contained package that fits into ham shack, living room, or listening post and at the same time is capable of camping trips and vacations where ac mains are not available. *R. L. Drake Company, 540 Richard St., Miamisburg OH 45342.*

HY-GAIN 3806 2 METER HAND-HELD FM TRANSCEIVER

The evolution of "portable" 2 meter equipment over the years has been amazing. Just a few short years ago, commercial surplus "boat anchors" were the rule. If nothing else, they did make for excellent traction by adding fifty pounds to the trunk. Times have changed. Even the diehards who insisted that they would never become involved are seen sporting the ultimate in amateur radio portability, the HT.

There are quite a few HTs on the market with a wide range of features over a wide range of prices. Initially, the arrival of a box here at *73* containing Hy-Gain's contribution to the HT field created little excitement. That changed, however, after a few minutes of using the new 3806 transceiver. The standard-looking blue external case hides an HT that is outstanding.

The 3806 measures 8½" by 3½" by 1¾" and could be a handful for a person with small hands. Its weight is surprising: only 2¼ pounds, complete with battery pack. The weight is kept down by the use of an ABS case that is highly resistant to damage and shock. At first glance, the case looks plain enough, but in the process of disassembling the unit, a few surprising features come to light. Hy-Gain Electronics makes a well-respected line of commercial radio equipment, and it's evident that they've included a few of the heavy-duty features in this part of their amateur line. The two parts of the external case are gasketed to preclude moisture getting inside and fouling up the works. The grill that covers the speaker and microphone is specially baffled to prevent water from getting in. Even the power pack is completely separated from the circuitry. Lifting it off reveals a sealed compartment, with two battery contacts the only evidence of its use. Admittedly, just about no one is going to use an HT under water. But most are exposed to a wide variety of climate, from rain to high humidity to salt spray.

The receiver section of the 3806 is much more than adequate. Hy-Gain claims less than 0.4 uV for 12 dB SINAD. I had no trouble backing up the claims and was able to have a QSO with another HT seven miles away while operating the 3806 inside my Volkswagen, with its horrendous ignition noise. Add to that the fact that hilly New Hampshire terrain and a noisy road were involved, and you have a perfect test for sensitivity. The 3806 came through with flying colors. The double conversion superheterodyne receiver with MOSFETs in the mixer and amplifier stages is superior to anything I've heard in a hand-held unit. The audio output power to the 2 inch speaker is ½ Watt and is more than adequate for just about any situation.

The transmitter section of the 3806 puts out a measured one Watt. Although that might seem low compared to a few other HTs on the market, it's more than enough for HT range. It also keeps the battery drain down. The unit only takes 380 mA on transmit. On squelched receive, drain is 20 mA; with signal, it's 100 mA. The battery pack takes 8 AA penlights or an optional nicad pack. The six channels (52 supplied) use standard 12 MHz crystals.

A few other features of the 3806 will appeal to the avid HT fan. All the controls are right out front. While transmitting, a large red LED stares at you, as an indication that a signal is really getting to the antenna. A meter indicates battery condition on transmit and relative signal strength on receive. A telescoping ¼ wave whip is supplied as standard equipment, although a rubber duckie is available as an optional accessory. More and more amateurs seem to be returning to the ¼ wave. The difference between it and the effective negative gain of a rubber duck is truly amazing.

Jacks for an earphone, external power, and external antenna are also supplied, each covered with a moistureproof plastic cover. The list of available accessories is long and includes a case, earphone, external antenna cable, cigarette lighter adapter, nicad pack, and a plug mount charger. At the time this went to press, Hy-Gain announced a tone pad that will fit flush into the back panel of the unit.

Suggested retail on the 3806 is $189.95, making it a moderately priced transceiver with features and performance that rival much more expensive units. It's built tough for outdoor use and should take the occasional abuse inherent in hand-held use in stride. *Hy-Gain Electronics Corporation, 8601 Northeast Highway Six, Lincoln NE 68505.*

HEATH HW-2036 2 METER TRANSCEIVER

In just about every endeavor there seems to be a "people's machine" — be it a Model T, a Volkswagen, a "Benton Harbor lunchbox," or a small portable TV. Utility these days demands a television and for most folks, a car. For hams these days, utility means 2m VHF gear, and the prices are getting lower and lower.

Heathkit got started with, among other things, amateur radio kits. Heath earned its reputation with DX-40s, AT-1s, DX-100s, and the company's famous SB line of tube transmitters and receivers. On the VHF side, Heath started out with the "lunchboxes" for 6 and 2 meters, the "Sixer" and "Twoer" as they were known. With the advent of FM came the HW-202, a crystal-controlled radio known for its high audio quality. Heath's first synthesized 2m rig was introduced in 1975.

The HW-2026, as it was known, sold quickly, but problems developed, and Heath became the only manufacturer on record to stage a full refund recall. Every 2026 customer was offered a full refund, and first crack at the rig's successor. A year later the new radio was ready, and somehow Heath had managed to get the price even lower! Suggested retail for the HW-2036 is $269.95.

The 2036 has gained quick national acceptance, just like its predecessor, and there have been no reports of problems. The 2036 works fine.

When we first got a look at the new radio, it had already been assembled at the Heath factory. Operating impressions were reported in January '77 73, so it only seemed proper to follow up with a construction review.

Upon arrival of the kit, I tore into the box, anxious to begin construction. There is no wasted space in the shipping carton; sub-packs and chassis parts are interlocked with the rest to form a cushion, an effective one since all parts came through FB. Chassis parts were in the bottom of the carton; the microphone was in a separate pack, as were the five circuit boards. The Heath method of subpackaging makes parts sorting an uncomplicated procedure; you can bet it would have been pure joy counting and sorting some 1,241 parts contained in the HW-2036 kit. Heath only packs the hardware you need to build and install each individual circuit board or assembly. Especially fragile parts (like the 2036's signal strength/relative power meter) are packed in styrofoam-lined boxes to insure safe delivery. If you're like me and like to peek ahead a little and see what all the parts look like, you'll also find the 2 final transistors in the power amplifier pack, which supply a minimum output of 10 Watts to the antenna.

The assembly manual is typically Heath — very clear and concise. Each part is clearly identified, and another great help is the scales Heath has printed on the bottom of each page whose steps require a measurement.

Heath does not stop its design work with the production of new gear. Instead, a constant updating process takes place, with owners kept abreast of what's happening. In the case of the 2036, four pages of corrections are sent along, with substitute parts included. The builder merely changes a few values in the assembly instructions, and tapes new pages over the existing ones — then you're all set to begin work.

During assembly, I did not use any special method for parts sorting. Since each board package was opened one at a time, the parts could all be laid out on the work surface. I grouped all the common value capacitors together, the same resistors, and so on (no reason for the traditional cookie tins or pie pans!).

The first step in assembly of the 2036 is the installation of scores of printed circuit board pins (PCB pins) on each lead extending from the wiring harness. This is quite tedious work, especially when the majority of the pins must then be wrapped in heat-shrinkable tubing. Once installed, however, the pins make for simple interconnection of the PC boards during final assembly and testing. Heath supplies a small alligator clip to hold the PCB pins upright, so you can place the wire right into the end of the pin, then apply heat and solder. I found it much easier and faster to make sure the wire to be inserted was tinned first, followed by heating the pin and melting a small amount of solder into it. Using that procedure, it takes a very small time interval to place each wire in a pin, apply a small amount of heat, and make a perfect connection.

By the time the first six hours of assembly time had passed, the chassis was complete and mounted in place, and the front panel meter, switches, and pots were installed. At about this point, with the rig taking shape, the hours of concentration began to pay off. The front face and control knobs complete the first lion's share of construction, and from there on out the work is less mechanical. It's time for the PC boards.

The first circuit board to deal with is the smallest, the voltage controlled oscillator (VCO) board. The VCO's job is to produce signal to the synthesizer for frequency selection. Construction of the VCO assembly is crucial because this stage must be stable enough to keep the synthesizer on frequency. For this reason, the board is installed in a shielded case on the chassis, and is the only board without IC sockets.

Soldering work on the circuit boards must be done carefully. Take your time, and save hours of troubleshooting problems later. After each board is complete, examine your work carefully for solder bridges, cold joints, etc. After a careful visual check of each board (preferably using Heath's X-ray views from the assembly manual), installation is accomplished with lock washers and nuts.

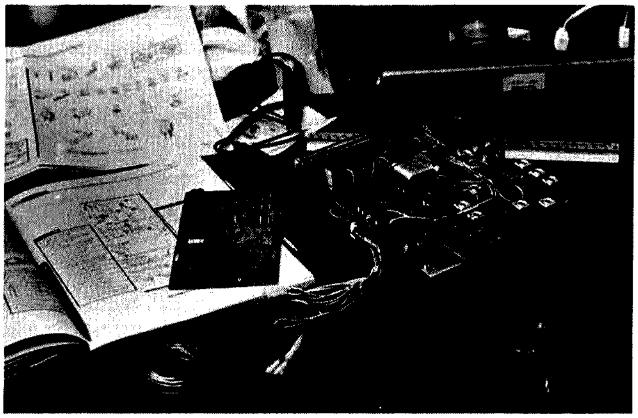
The next step is to plug all those beautiful PCB pins into the posts on each board. You'd never think you'd be glad to see another one of those pins after you finish soldering them all, but they really are fantastic. You should, however, be careful to route all wires from the harness in their correct positions, or you may find yourself taking apart half the radio to fix a minor mistake. Pay special attention to wires going around the speaker assembly and see to it they are routed straight back and *under* the VCO shield. This will make for easier hookup later between the synthesizer and receiver boards. Also be careful when installing the VCO board on its mounting posts. The six 1¼" wires that go to the coupling capacitors on the shield could very easily get pinched. Try to route them on a smooth path out from between the board and shield. One more point on the VCO board: Be sure the insulation of each lead is snug up to the board. Stray wires hanging around could short on the two-sided board.

see page 191

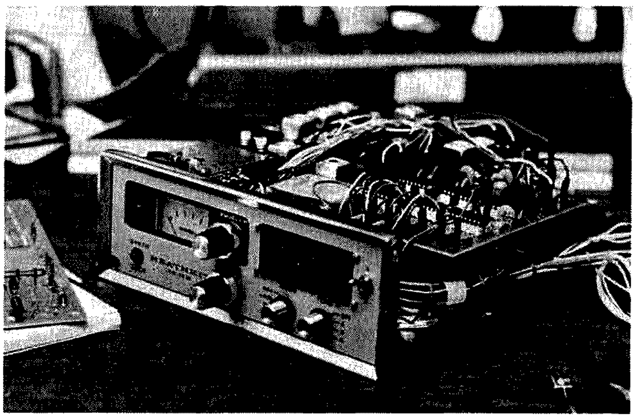
Space is limited in the rear portion of the 2036, where the power amplifier goes. The board is fastened to the back panel with screws, spacers, and the final transistors. Make sure you bend all the capacitors over towards the board when you install them, so when the time comes to put the whole unit together, you won't risk damaging them. Two heat sinks are mounted on the back panel after alignment, allowing for easy access to the PA during alignment.

Alignment requires only a VTVM and a receiver capable of copying WWV. I used a 1 Hz to 120 MHz frequency counter for maximum accuracy in setting the transmit and receiver offsets. All alignment cables, tools, and even a dummy load are included by Heath. The builder is instructed to build the dummy load out of two 100 Ohm 2 Watt resistors in parallel and a phone plug. (This assembly can be put aside after completing the kit to serve as a dummy load for future projects.)

The signal strength/relative power meter is used in alignment of the receiver, and also in peaking the transmitter and power amplifier boards. Later on, the transmitter board is used to provide a low level signal for peaking the receiver. Of course, if you owned a bench full of test equipment, alignment could be done with a signal generator, but Heath keeps the process pure and simple. The 13 pages of alignment took a total of 3 hours, making the total construction time 29 hours and 45 minutes from cracking



Past the halfway point in construction of the HW-2036. Note the Heath assembly manual and fold-outs.



Partial assembly of the HW-2036 from another view, with scores of PCB pins running off the wiring harness.

the box to making the first QSO.

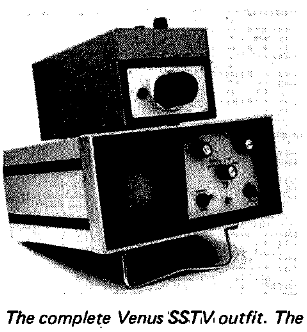
If there's one failing of the Heath 2036, it's the lack of dial lighting on the thumbwheel switches used for frequency selection. One solution would be to drill a mounting hole into the front panel, just over the switches. That may be less attractive than an outboard mount, to minimize damage to the radio, especially if the illumination solution is attempted after construction is complete. With the help of W1ZAW, we came up with an outboard solution requiring no drilling and no circuit modifications.

All you need is a one inch piece of polystyrene (color doesn't matter), a Sylvania type 12ES 12 V bulb, and some Eastman Kodak type 910 cement. If you want to use a 6 V bulb (Sylvania 6ES), we suggest a 47 Ohm ½ Watt resistor.

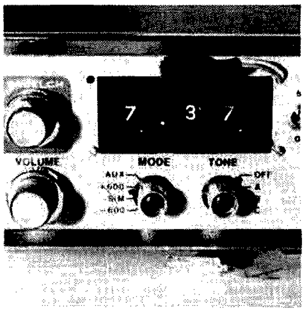
To install the dial light, remove the top and bottom covers per Heath's instructions. Then remove the upper right-hand mounting screw, washer, and bolt from the thumbwheel switch assembly. Using number 20 insulated wire, color keyed for B+ and ground, solder the leads onto the bulb as close to the base as possible. (Be careful to avoid shorts at this point.) Run the leads through the front panel (using the now empty switch assembly screw hole) and dress the wires across the top of the switch assembly case. Solder ground to the lugs on top of the VCO board case, and the B+ lead to the 12 V line running between the synthesizer lock and signal indicator LEDs. This completes the wiring.

To mount the dial light, first glue the polystyrene strip (centered) above the thumb switch assembly on the front panel. Be especially careful not to get any of the type 910 glue onto your fingers or hands – Eastman says surgery has been necessary in cases where people ended up gluing their fingers together! Next, glue the bulb (as shown in the photograph) onto the polystyrene, making sure that the bulb protrudes at least ½ inch beyond the front panel. Finally, tape (with electrical or mystic tape) over the top and front of the bulb to direct the light downwards towards the switches.

Heath did choose very bright markings for the calibrations on the thumbwheels, so it isn't necessary to get a great deal of light on them for illumination. Shoot for the least possible light necessary to prolong the life of the bulb. Another point to watch is that the bulb and its wiring leads are



The complete Venus SSTV outfit. The camera has a built-in slow scan bar generator; the monitor is available either as a kit or factory assembled.



Lighting mod, as described in the text, for the Heath HW-2036.

mounted far enough above the switches so as not to interfere with their operation.

Normally, Keene NH, being the valley it is, is not what you'd call an outstanding VHF location. But with the 2036 and a CushCraft Ringo Ranger antenna up 30 feet, I could work 04-64 in Waltham MA (just outside Boston) regularly. In my judgment, the receiver is quite hot, and certainly consistent with Heath's claim of .5 uV for 12 dB SINAD. A great addition to the rig is a sub-audible tone encoder which can be set up for three different tones for repeater access.

If you run across a problem with the synthesizer not locking when you bring the rig out into the cold car, try tweaking the synthesizer in a colder atmosphere. A fellow on the Maiden MA 19-79 machine suggested the above after his problems with the cold.

Three other stations running HW-2036s were contacted almost immediately after construction was finished. They all raved about the radio and had experienced no major problems in assembly. Performance of the HW-2036 over the last month and a half has been very consistent with what you'd expect on the basis of company specifications. And the fact that any problems down the road won't force me to send the rig back to the factory is a good feeling – since I built my rig, I'm not afraid to tear into it. How many of you can say that?

Paul Hebert WA1VJI
Keene NH

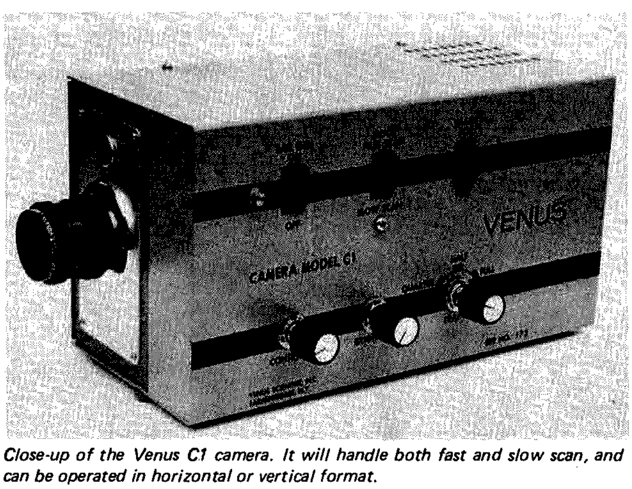
VENUS SCIENTIFIC INC. C1 CAMERA SLOW SCAN/ FAST SCAN AND SS2 SLOW SCAN TV MONITOR

Not being really involved with SSTV, I was hesitant to accept the assignment to test and review Venus Scientific's C1 Slow Scan/Fast Scan Camera and SS2 Slow Scan TV Monitor. In fact, up until that time, I was not very impressed with any of the slow scan systems I had seen.

I reluctantly carried the equipment home into the shack. I opened the boxes with all intentions of spending the remainder of the evening soldering wires and adjusting sync controls. As I opened the first carton, what appeared was a 4-3/4" x 10" x 5½" box with a lens on one end. It was the C1 Camera. Along the top were the slow scan controls (three knobs and three rocker switches). The knobs control the contrast, brightness, and framing. The rocker switches are for the bar generator, mode (fast or slow scan) selection, and positive/negative image. On the rear panel there was a six pin male Jones plug, a focus control, an output socket, a power switch, and an ac power cord. An accessory cable, video cable, and instruction manuals were included in the carton.

The other box contained the SS2 Slow Scan Monitor. The monitor measures 10-3/4" x 12" x 5". The front of the monitor, besides containing the screen, has five controls. These are for brightness, contrast, power off/receiver/tape/camera, accu sync/re-scan, and voice/video. The back panel contains sockets for inputs from a slow scan camera, a receiver, a tape deck, a microphone, and a telephone line. There are outputs for a tape deck, the transmitter microphone input, and 115 V ac. An accessory socket is also provided.

This brought me to the realization that I would not be in for a night of soldering. The accessory cable connects the 6 pin Jones plug on the camera to the accessory socket on the back of the monitor. I did this and plugged the units into my household current. I turned the monitor on first (as was specified in the instructions), and then the camera. I connected a cable from the rf output of the camera to the antenna terminals of my TV set, turned the set to channel 3 (this channel is preset at the factory, but any channel between 2 and 6 can be set), and pressed the button on the camera back which switches from video to rf output. Just like that, there was a blurry picture on the screen of the TV. I adjusted the focus and whammo! There was a fantastic picture. No soldering, no fooling with controls! It was a 15 minute process.



Close-up of the Venus C1 camera. It will handle both fast and slow scan, and can be operated in horizontal or vertical format.

The next step was slow scan, and this I "knew" would take some time. I rotated the camera 90 degrees, as is necessary when changing from fast to slow scan. This puts the slow scan controls on the top of the camera. I made sure the image was focused on fast scan, then I switched the rocker switch to slow scan. I rotated the frame control to full frame. Then came a very impressive procedure which is outlined in the instruction book. I set the mode switch on the monitor to "accu sync" and turned on the bar generator on the camera. I then rotated the contrast control on the camera fully clockwise and adjusted the brightness control so that the display on the monitor clipped equally on the top and bottom. I then adjusted the contrast control until there was little or no clipping. Then I turned the monitor back to operate, touched up the brightness and contrast on the monitor, and there it was! A perfectly adjusted clear slow scan picture forming right before my eyes. A five minute process from fast scan to slow scan!

I just couldn't believe it was that simple. Over the course of the evening, instead of soldering and syncing, I was having fun. I made tapes of various pictures and played them back. I let the kids put on their own TV show with the fast scan. I just couldn't wait for the weekend to try it out on 20 meters.

The weekend finally came and I was set. I had the TV equipment interfaced to my rig and was ready to go. First I just listened and copied signals. Perfect copy on clear signals I recorded and later reviewed. At last it was time for me to try my hand at sending pictures. I listened around 14.230 MHz until I picked up a station in Florida. After a brief explanation that this was my first SSTV QSO, I sent my first picture. The report was excellent and I was on my way. I spent the rest of the afternoon having fun again.

My one regret is that there is not very much ATV activity here in New Hampshire, but I am trying to stimulate some interest so I can use this camera on VHF.

In that one evening, my whole idea of amateur TV, be it slow or fast scan, changed. I learned you do not have to be a video technician to enjoy its rewards and, if you use the right equipment, the results are very impressive. It has made a believer out of me and I hope to enjoy many years at this facet of our hobby.

The Venus camera and monitor would be an excellent choice for anyone interested in amateur TV, be he a newcomer or old-timer. Maybe someday we'll have a QSO and you can copy my pix.

Venus C1 Slow Scan/Fast Scan

Camera $385; Venus SS2 Monitor Kit, $235; wired, $285. *Venus Scientific Inc., 399 Smith Street, Farmingdale NY 11735.*

Rich Force WB1ASL
Associate Editor

HUFCO DIGI-DIAL ADAPTOR

Hufco of Provo, Utah, has come up with a neat little device for hams who have a counter and would like to use it for transceiver direct frequency readout.

Known as the Digi-Dial Adaptor, this unit heterodynes the output from the transceiver variable frequency oscillator (VFO) with a variable crystal oscillator (VXO) frequency generated in the Digi-Dial Adaptor, to produce a 2.0 to 2.5 MHz frequency for the input of a digital frequency counter. The VFO must generate a frequency of 5.0 to 5.5 MHz. The actual readout of the frequency counter will depend upon the number of digital readouts available, but there must be enough to permit 2.000 to 2.500 MHz to appear, in order to be useful. The first digit (2) is ignored, and the reading 000 to 500 represents, directly in kHz, the frequency being received or transmitted for any amateur band, with some over-coverage. For instance, assuming the bandswitch was set for 14.0 MHz, the frequency will be understood as reading from 14.000 to 14.500, but will appear as 2.000 to 2.500.

The circuit of the Digi-Dial Adaptor accommodates either VFOs that compensate for upper and lower sideband shift (such as Heathkit), or those that do not.

Prior to purchasing the Digi-Dial Adaptor, I inquired of Hufco regarding whether or not the unit would operate with my particular transceiver — a Heathkit SB-101. A very prompt personal reply from Jim Huffman WA7SCB assured me that it would, and I placed an order. Within days I received a card telling me that shipment would be made in about a week, and sure enough, it arrived on schedule.

From the very start, I was pleased with the production of this kit. All parts, including the circuit board, were enclosed in one plastic pack, with the individual items of a similar nature grouped so that it was very easy to check.

The board is excellent — with a good commercial etch and outstanding plating characteristics, soldering is a breeze. Drilling is perfect, and the component side is screened for all component identities.

Important connection points are additionally identified on the etched side of the board. On the board I received, two transistors had the same board designation, but this created no problem because both transistors were of the same type.

Parts in the kit are of premium quality. Four similar encapsulated inductances are marked in microhenries in the standard color code, which makes any errors in the installation of these practically impossible.

The instructions accompanying the kit are very extensive and complete, considering the size of the kit. However, this is certainly not a detraction, because every one of the 16 pages is helpful, providing as it does, theory of operation, parts list, assembly instructions, tune-up, many diagrams, etc. One photograph, which has application only to anyone who is using the adaptor with one of Hufco's counters, has not reproduced well. The circuit diagram of the unit includes all information ever needed for servicing, such as exact normal voltages at every component operating point, all values, all designators, and all external connections.

A problem became apparent with my adaptor at turn-on time. Troubleshooting the unit using the excellent schematic voltage references quickly identified an FET as the culprit. It is entirely possible that this was zapped during handling (even though this device is diode-protected), as the humidity at the time was around 10% and static charges easily accumulated, which only emphasizes the need for care in handling these devices.

A note to Hufco brought an immediate replacement in the next mail. Following installation of the new FET, no further problems were encountered, and, after putting the VXO on frequency, installation to the VFO was simple. Installation for each transceiver make is a little different, but the manual clearly describes hook-up for all currently popular transceivers. Power supply circuitry is part of the Digi-Dial board assembly, so that the only external requirements are 6.3 volts ac. Five volts dc may be used directly if desired.

About a month after receiving the kit, I was pleasantly surprised to receive a postcard from Hufco hoping that I had the kit working and offering help if I had any problems. A nice gesture.

For those looking for a unit that will perform as stated, the Hufco Digi-Dial seems to be the answer from all points of view. Priced at $39.95 for the kit, and $49.95 assembled, shipping charges paid, it is available from *Hufco, P. O. Box 357, Provo, Utah 84601.*

Hufco's Digi-Dial Adaptor.

COMMUNICATIONS ELECTRONICS INTRODUCES THE BEARCAT 210

Communications Electronics has introduced its new 5 band, push-button, programmable, crystal-less super synthesized scanner. Named the Bearcat 210, this unique scanning instrument gives the user push-button access to more than 16,000 different frequencies including 2 meters and the entire 3/4 meter amateur band.

The Communications Electronics Bearcat 210 is literally packed with exclusive space age electronic advancements and features. Completely synthesized circuitry, including Bearcat custom designed integrated circuits, makes possible lower cost and higher reliability.

The user never needs to worry about buying crystals. The synthesizer circuitry permits one to enter or change any ten frequencies in a matter of seconds. The unit will then scan those frequencies at a rate of 20 channels per second. A large digital input and readout display allows the operator to *see* the frequencies he has selected, as well as the frequencies currently being broadcast. Rolling zeros on the large LED display, a Bearcat exclusive, also indicate channels being scanned.

The *search* feature on the Bearcat 210 is fantastic! With this feature, you can locate and identify the frequencies that are currently in use by reading the frequency directly from the seven segment LED readout. This makes this scanner ideal for discovering those "hidden" or nonpublished frequencies.

In addition to an automatic frequency search feature which allows the operator to listen to *selected* segments of the different frequency bands, there is a selectable two second scan delay that permits the listener to hear all the excitement and prevent missing transmissions when "calls" and "answers" are on the same frequency. A push-button lockout feature allows selective skipping of those channels not of current interest. Other features include 117 V ac or 13.8 V dc, a large front speaker with 2 Watts rms output, slope front for easy programming and vehicular use, patented track tuning, tone bypass, and many of the traditional features that have made Bearcat scanners the most sophisticated ones at Communications Electronics. The Bearcat 210 covers 32-50 MHz, 146-174 MHz, and 416-512 MHz, with a sensitivity of 0.6 uV for 12 dB SINAD on low and high bands.

The Communications Electronics Bearcat 210 is mail order priced at $319.95, and CE still offers their unique "guaranteed lowest price" sales policy. You can place a telephone order on their toll free USA 24 hour order line 800-521-4414 and charge it to a BankAmericard or Mastercharge. In Michigan and outside the USA dial 313-994-4441. To order by mail, or for a free catalog including a four page full color brochure describing the Bearcat 210 as well as CE's other electronic products, write: *Communications Electronics, P.O. Box 1002, Dept. RS-3, Ann Arbor, Michigan 48106 USA.*

The Bearcat 210 programmable scanner.

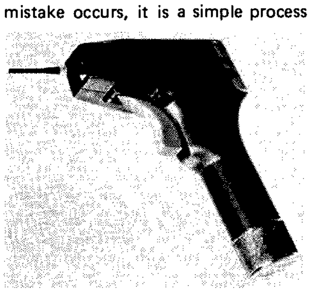
OK MACHINE AND TOOL CORPORATION'S HOBBY-WRAP TOOL

If you have ever built a microprocessor kit, or any other complex digital device, you know soldering is not the ideal way to make hundreds of interconnections. The technique of "wire-wrapping" allows easy circuit construction, and when the inevitable mistake occurs, it is a simple process



The OK Machine and Tool Corporation Hobby-Wrap Tool.

to disconnect and rewire the offending connection. A special wire-wrap tool is required to correctly and securely "attach" the wire to IC sockets. These tools range from simple hand-operated devices that are useful for very small jobs all the way to bulky ac-operated devices with the associated power cord.

The best approach to wire-wrapping is the Hobby-Wrap Tool, manufactured by the OK Machine and Tool Corporation. This wrapping tool is motor driven for ease of use, yet is battery operated, eliminating the trailing power cord. The device is powered by two size "C" cells, and weighs only 11 ounces. The wire bit accepts standard 30 AWG wire for .025 inch square DIP stakes. The bit produces the "modified" wrap, which wraps a two turn layer of insulation around the stake for complete mechanical security. I used the tool to wrap a CPU board and found it a pleasure to use. Each wrap was uniform, and the battery-powered motor allowed complete flexibility when maneuvering into tight corners on the board. The battery lasted for the entire session. The best feature of the rugged Hobby-Wrap Tool, however, is the price. The device is available for $34.95, which puts professional wire-wrapping within the means of every serious hobbyist. *OK Machine and Tool Corporation, 3455 Conner St., Bronx NY 10475.*

NEW HAMTRONICS CATALOG

A PA/preamp unit for 2 meter walkie-talkies, 6 new test probe kits, and a VHF FM receiver kit model are featured in the new Hamtronics catalog. The 24 page edition contains a wealth of gear, including UHF FM receiver and transmitter kits, scanner adapters, multichannel adapters, and a vast array of ac power supplies. To receive your copy, write Hamtronics, Inc., 182 Belmont Road, Rochester NY 14612. It's yours for an SASE.

SOLDERLESS, CABLE-MOUNTED FEMALE UHF SERIES CONNECTOR

A new "In-Line" SO-239 type connector for both OEM and field application use has been introduced by Gold Line, the nation's largest manufacturer of CB accessories.

A Gold Line spokesman said that the units are available for RG-58/U type cable in both bulk for OEM use and single packaged for the distributors' shelves. The No. 72 series connector eliminates the need for double female splice connectors (PL-258) when additional cable lengths are required. A unique crimping of the center conductor is featured with manual or production ferrules available along with production tools. The model 72-F designates a completely solderless, field-assemblable unit intended for sale through the Gold Line national distributor system. Gold Line designs and produces a complete line of accessories for the CB, ham and marine radio markets. *Gold Line Connector, Inc., P.O. Box 893, East Norwalk CT 06855, (203) 853-1211.*

BRAMMALL BARRELS

Various locking devices are available to prevent the ripping-off of your transceiver, stereo, etc. But as someone has said, "A lock only keeps out an honest man" — and this applies to any of these devices when confronted by a determined thief who has plenty of time.

Now there is a lock available which probably makes the rip-off about as tough as possible for any thief. Designed originally for CB transceivers, it may be used equally as well for any bracket-mounted amateur transceiver, stereo radio, or cartridge/cassette player.

Incidentally, most insurance companies will insure a mobile radio which is *locked* in, without applying the additional premium for "CB/8 track."

Several unique design features have been included in this rather simple locking device, known as the Brammall Barrels. As shown in the photograph, a tapered cylinder fits over the hole for each of two of the mounting screws, which are replaced. After tightening the screws, the barrel lock including key is inserted in each of the cylinders, and, once the key is removed, the lock barrels prevent access to the screws on each side of the mounting bracket.

The purpose of the tapered barrel is to prevent a thief from breaking off the barrels with a pipe — a frequent method of stealing a unit with non-tapered similar locks. The manufacturer claims a unique preventative to another act of thievery whereby the chief inserts a screwdriver in the key slot and works the barrel off. Because Brammall Barrels cylinders spin freely once installed, the barrels cannot be twisted off. Each key is individually keyed to the lock with which it is supplied, thus making the possibility of duplicate keys from the manufacturer almost non-existent.

At $9.95 a set, the Brammall Barrels provide about the least costly form of theft insurance available today. They are available in most CB, amateur, and hi-fi outlets. Manufactured by *Brammall, Inc., Box 208, Angola, Indiana 46703.*

1977 AMATEUR RADIO EQUIPMENT DIRECTORY

The most complete buyer's guide ever on amateur radio equipment has been published by Kengore Corporation. Over 130 pages and 70 different manufacturer/distributor listings are included, along with one element traditionally missing from product ads — list prices. Recent letters to the editor would indicate some frustration with the lack of prices in manufacturers' ads, and the '77 equipment directory is bound to go a long way towards plugging the information gap. Not only are prices included, but each product is well illustrated with a photograph and the most complete listing of specifications possible. Many of the pages will be familiar to readers of *73*, since the publisher used a large number of ads and manufacturers' brochures that have appeared in the various magazines. In all cases, Kengore has added the prices and, where necessary, additional information that may have been missing from the original. The *1977 Amateur Radio Equipment Directory* sells for $2.95 and will undoubtedly be in demand among hams and would-be hams, whether their interest is horse trading, buying, or just drooling over what gear they'd like to have. (The directory may not be too popular among wives, parents, or others concerned about amateurs spending money.) The directory is available from *Kengore Corp., W2TGH Editor/Publisher, 9 James Avenue, Kendall Park NJ 08824.*

O.K. TOOL'S SPEED-WRAP TOOL

The new G200/R3278 Speed-Wrap Tool is designed to produce solderless wire-wrapped connections by merely squeezing the trigger. The hardened steel working parts ensure long life and troublefree service. It is enclosed in Lexan (Trademark of General Electric Company) housing, enabling the tool to be light in weight, and is designed for production line and field service use in the electronic, telecommunications, and appliance industries. For 22-30 AWG.

Wire-wrapping provides a positive, uniform, "gas-tight" connection. *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.*

RF TRANSFORMER MATCHES VERTICAL ANTENNAS

Palomar Engineers has introduced a wideband rf transformer rated at 5 kW PEP (2 kW CW CCS) from 1-30 MHz. Taps are provided to match 50 Ohm coaxial cable to 32, 28, 22, 18, 12, 8, or 5 Ohm antennas. The transformer is unbalanced-to-unbalanced for use with short vertical and whip antennas.

Quarter wave antennas or short verticals that have been resonated with loading coils can be matched to 50 Ohm coaxial cable by selecting the proper tap on the rf transformer. In many cases, the transformer can be used instead of an antenna tuner. It is much smaller than a tuner of equivalent power handling capability, is less expensive, and is more efficient. It has particular application to phased vertical directional array.

The transformer is wound with teflon insulated wire on an rf ferrite toroid core, has UHF (SO-239) connectors, and is epoxy encapsulated in a white PVC case so that it can be used in any climate. Loss through the transformer is less than 0.1 dB. Size is 3½" diameter and 2½" high. Price is $42.50 postpaid in U.S. and Canada. For additional information, write to *Palomar Engineers, P.O. Box 455, Escondido CA 92025.*

Ham Help

This is a plea on behalf of blind hams, at least in this area. I teach ham radio at the local Braille Institute, and the blind hams I know need an audio meter for tuning transmitters. Despite about a dozen contacts on the air with hams who know just what is needed, I have yet to receive further information.

Even though I feel I have little time for building projects, the one article I have been able to find in ham magazines contained junk box parts that no electronic supplier could identify or provide a replacement for. A commercial source is the most desirable; however, a simple schematic composed of obtainable parts certainly would be acceptable.

Any help will be greatly appreciated.

Searle L. Bennett
2656 Riverside Drive
Costa Mesa CA 92627

You have recently published a number of circuits for programming the number 8223 PROM, manufactured by Signetics. Unfortunately, Signetics has discontinued the 8223 and replaced it with the 82S23. If an effort is made to program the 82S23, using the circuits designed for the 8223, nothing will happen. The links just won't blow out.

The *Signetics Bi-Polar Memory Book* gives a schematic for programming the 82S23, but it is an extremely complicated pulse generator, using all kinds of hard-to-get ICs.

I have experimented, and I have found the simple circuit enclosed to be effective in programming the 82S23. The same circuit — which is based on a design put out by Southwest Technical with some of their kits — can also be used to program the DM8577 and 74188 PROMs. When programming DM8577 PROMs, the circuit will change logic ones to zeroes. When programming 82S23s, the circuit will change zeroes to ones.

There is nothing special about the power supplies. The 18 volts can be derived from a variable bench supply or from three lantern batteries connected in series.

To use the circuit, you set the address switches to the word to be programmed. You then throw SI to the program position and set S3 to the bit to be programmed. Momentarily (less then ½ second) push S2. Then return SI to the "read" position and observe the LED to verify that the bit has been programmed to a one or a zero, as the case may be.

Because this is not a factory-recommended circuit for the 82S23, I can't guarantee that it won't harm the PROM. I can only say that I've tried it on 82S23s and DM8577s and have experienced no difficulties. Nevertheless, users should work slowly to avoid excessive heat buildup, and push S2 only briefly.

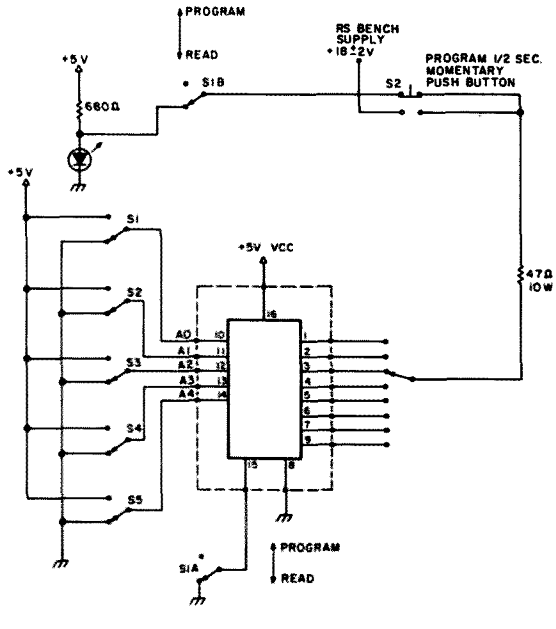
Frederick MO



Do you know where I can obtain conversion information for the R-15 receiver?

Robert Eckard K3PFU
RFD 3 Box 162
Cogan Station PA 17728

I have run into a problem. I now have the Heath SB-301, SB-303, and the Heath SB-401 transmitter. What I would like to do is to use either the SB-303 receiver and the SB-401 transmitter together (transceive) on a Navy MARS frequency, or the Heath SB-301 receiver with the Heath SB-401 transmitter (transceive). As it stands now, the Heath equipment will only go as high as 4.00 MHz. The Navy MARS frequency on which I wish to operate is 4.045 MHz, so I need about 50 kHz outside of the 80 meter ham radio band. What I would like to know is If there have been any articles on using the SB-303 and SB-401 or the SB-301 and SB-401 on Navy MARS frequencies (outside of the amateur bands). If not, can you please give me some idea of how to go about changing the equipment to operate outside of the 80 meter amateur radio bands?

Everett C. Bollin WA3DVO
2543 Perring Manor Road
Baltimore MD 21234

First of all, I want to let you know I think your magazine is great. Just can't wait until the first issue of *Kilobaud* arrives. I already take *Byte*, so with the two magazines, plus the I/O articles in *73*, I should be able to digest enough info on computers. I'm still in the studying phase of computers; my Navy salary won't allow me to purchase one. I'll solve that problem about a year from now.

Also, I want to thank WA9VFG for his article in the Holiday issue. I do a lot of designing using ICs, and his method has really saved me some headaches on my latest project. Wish I had known of It earlier. (While on the subject of ICs, if anyone in the Jacksonville area needs help with digital logic, especially TTL, get in touch with me.)

I'm not a ham yet. I'm working on code now. Will attempt to get my General license in April when the next exams are given in Jacksonville. I already have my first class phone ticket, so I'm not anticipating any problems with the theory section.

Now for my appeal for help. I would like to correspond with anyone who is interested in the 1750 meter band (160-190 kHz). I'm really needing some antenna ideas. The FCC rules and regs on this band are few. Anyone wanting to know them, send me a SASE and I'll be happy to reply. I don't expect to be able to establish a reliable net on this band, but the experimentation should be fun. Any pioneer spirits left out there?

Calibration Lab
U.S. Naval Station
Mayport FL 32228

I would like to get in touch with other amateurs using MTTY (Morse teletype decoders and keyboards) for possible net activity. Thank you.

Mike Stone WBØQCD
1110 East 4th St.
Durant IA 52747

Please inform the writer just how he can learn the Morse code! I have purchased records, tapes, and that cassette that the ARRL puts out with no results. I understand that a 9 year old can learn the code in a couple of weeks, but I'm 60 years old and have been at this for the last four months. I know the code, but I just can't receive it. I've signed up for a radio operating course at one of the colleges here in Milwaukee.

I've never had trouble with the different languages I've learned, so I'm beginning to think there is a gimmick or something ... Any information you may give me would be appreciated. I'm a subscriber to your mag and enjoy it very much!

Robert C. Norton
3162 So. Hanson Ave.
Milwaukee WI 53207

Try the 73 code courses, Bob. Thousands of delirious hams will attest to their value. — Ed.

I need information on the SSR-4 receiver that covers the 50-200 MHz range.

F.G. Senker K4OKD
436 Wallace Drive
Charleston SC 29412

This is the former RAE5/LU2AX, about to make a comeback as a W6 or K6. Coming close to my 74th birthday, the one who was "bitten" by the radio bug back in 1922 must go back to "pound the brass" (even if now the "brass" is a Ten-Tec RK-20A).

I am about to start trying for my American license. So I am thinking definitely in terms of equipment. To begin with I have gotten a Hallicrafters SR-150: yes, one of those "orphans." In reception it is working beautifully on the three indoor half-wave dipoles that I have set in the camera-room of "PHOTOG," my "studio" here in San Jose. BUT ... I haven't been able to secure a copy of the instruction manual for that transceiver.

I wonder if *73* can guide me to obtain one, either original or a photostatic copy. I am a bit lazy to start tracing each and every circuit and prefer to buy a manual.

By the way, here is an idea for a possible addition to your "line" of tapes for radio amateurs: How about a two-tone short one for tuning SSB transmitters?

An "old dog" in this matter of radio publications (I was first Technical Editor for Argentina's "REVISTA TELEGRAFICA"), I most certainly do appreciate your efforts to make *73* one of the best of its kind in the world. It is a real pleasure to see the work of a real "pro" and this last "Holiday 1976" edition is *TOPS*.

May 1977 be good to you and to your magazine. You most truly deserve the reputation already attained in "hamdom"!

Segundo P.I. Acuna
142 Graham Ave. #5
San Jose CA 95110

PS. I hope that your 14 and 21 wpm tapes will "unrust" my code to take me up to an "Extra" sometime soon.

I want some Ham Help on code. I would like to get with some lady, man, or boy who wants practice on code. I have been off the air 26 years — had a Novice, then a Technician license for over 20 years. I had a heart attack a few years ago and the license lapsed. Then in 1976, on April 6, I got another Novice license. Up to date, I have had one contact on 15m —

nobody answers my calls, and I know that my code is no worse than others that I hear call. I am 84 years old. I call every day, but no luck so far. I have been using a vertical antenna, but I am going to a long single wire antenna to see if that will make a difference. I think most hams are on the snobbish side, the way they have acted toward me. If I could get a contact further away from here, it would suit me fine. I'm hoping that you could recommend some ham who is having the same trouble as I have been having. Thanks for the trouble that I am making you. I will say that you have a great magazine.

Glenn N. Crawford WBØSLV
207 5 Ave. N.
Humboldt IA 50548

Last year about this time I bought the *Slow Scan Television Handbook* from the British ATV club. I decided to build the W7ABW/Ø plumbicon camera. After a great deal of trouble getting components and making the focus and scan coils, I did manage to make up all the circuits, make the chassis, and put it all together. However, the camera doesn't work.

I wonder if there are any mistakes in the schematics in the values of the components. As I do not have a thorough grounding in electronics, I wouldn't be able to spot any mistakes. It would also help greatly if I could obtain photos of oscilloscope traces for the alignment procedure, especially 50 MHz.

I would also like to know if the transistors are critical. I made the following substitutions: 2N718 for 2N1711, 2N722 for 2N2907, 2N3117 for 2N930, and 2N697 for 2N1711.

Any help that you could give me in getting this camera to work correctly would be greatly appreciated.

Paul Kaminski GM3PIB
5 Tytler St.
Forres, Murrayshire
England IV 36 ØEL

I've got a problem. I just purchased a 10-80m vertical antenna and I just don't have the room for all the radials needed to make the antenna resonate properly. I have to fit the antenna and all 10 radials (2 for each band) on a 28' x 52' roof.

I can't use any part of my backyard because it is divided up by three sets of overhead power lines and three telephone lines. The yard is only 30' x 30' anyway. My question is this: Can the radials be shortened physically somehow and still be electrically correct? The 80 and 40m radials are the real problems.

I think there are quite a few other city dweller hams who face the same problem I do.

Any help or suggestions from you or your readers would be appreciated by all of us. Thank you.

Ken Gustafson WB9ZPN
5149 W. State Rd.
Burbank IL 60459

I have, for a long while, been trying to get hold of a copy of your article concerning coaxial dipoles, which you published in June, '73, in *73 Magazine*. I have been unsuccessful thus far. I am therefore hereby trying to get it "straight" from the horse's mouth." I intended to build a 40m coaxial dipole and did try one, but I guess the calculations are incorrect, so I would be much obliged if you will help me out.

As far as W2DU's rude comment and article – forget it. I read it and since it is a whole lot of theorizing, I am yet to believe it until proved. Your idea that it works has been proved and therefore bears much merit.

Thanking you and looking forward to your reply.

Dennis P. Sladen VE3DPS

Sterling IL 61081

Review

AN INTRODUCTION TO MICROCOMPUTERS
Volume II – Some Real Products
by Adam Osborne
and Associates $12.50

This is the second, and by far the largest (865 pages), of Mr. Osborne's four volumes on microcomputers. The first volume dealt with the basic concepts of computing in general and microcomputers in particular. The remaining two volumes are concerned with the application of two specific devices, the 8080 and the 6800, to system logic design.

Each chapter of this volume analyzes one of the currently available microprocessor/microcomputer devices. Virtually all the most popular microcomputers are covered and every type of architecture is discussed. There are 4-bit, 8-bit, and 16-bit machines, chip sets, single chip computers, and chip-slice devices. The 8080A, MC6800, Z80, and MCS6500 are dealt with in the greatest detail, but there is still a wealth of information presented for other systems. Many of the chapters are 60 to 80 pages long and the chapter on the 8080A, which is 176 pages long, would itself make a fair-sized book.

Like all of Mr. Osborne's books, this one is noteworthy for the thoroughness of the presentation and the immense amount of detail. The treatment of the 8080A is especially remarkable. The internal workings of the 8080A and of all the various accessory devices are explored down to the last trailing edge of the last waveform. Some of the information presented is simply a reprint of manufacturers' published literature, but much is original. The total result is a truly comprehensive analysis of 8080A microcomputer hardware and its workings.

Although the treatment of the 8080A is the most extensive, it differs from the other chapters only in degree. A typical discussion covers everything from the pin assignments on the chip to the intricacies of the timing for complex control tasks and data transfers. An instruction list is, of course, provided for each device with a symbolic description of the operation executed by each instruction. Insofar as is possible, this book tells everything about how a machine performs a given operation and the status of all lines, registers, and devices before, during, and after the operation.

However, this is essentially a hardware book and, as such, is not of equal value to every reader. For the professional digital engineer, whether his interest is his personal hobby or his on-the-job assignments, this should be an invaluable reference. For the computer hobbyist who is not a professional, the value of the book is less clear cut.

Mr. Osborne's preceding book, Volume I of the set, was a beginner's book, which assumed that the reader had little or no knowledge of digital technology. The presentation began with the basics of computers in general and worked up to the consideration of microcomputers in particular. Volume II is not really a continuation of Volume I except, perhaps, for the professional engineer looking to master microcomputers for his job. It is a reference book rather than a tutorial text, and it is a reference book for use on hardware design projects.

Many hobbyists are essentially programmers. Their basic machine was an assembled and operational computer when they obtained it. Their hardware involvement is the bare minimum necessary to expand their system with a new device or kit and they have no desire to expand that interest. They want to *use* the machine as it stands. In this case, there is little value to them in the detailed analysis of internal logic and timing.

The final decision naturally rests with the individual. Each reader knows the extent to which he is involved with, or wishes to be involved with, his microcomputer hardware. If there is any considerable involvement and if that hardware is one of the systems treated in this book, then Mr. Osborne's book should prove to be a valuable and frequently used reference. *Adam Osborne and Associates, P.O. Box 2036, Berkeley CA 94702.*

MOS AND SPECIAL-PURPOSE BIPOLAR INTEGRATED CIRCUITS AND RF POWER TRANSISTOR CIRCUIT DESIGN
Texas Instruments
Electronics Series,
Published by
McGraw-Hill Book Company,
$16.50

Designed a memory system for your micro lately? If so, you are aware of the timing problems, chip selection, and interfacing involved in such a project. Next time, refer to "MOS and Special-Purpose Bipolar Integrated Circuits and RF Power Transistor Circuit Design," by the Texas Instruments staff. This reference provides design information, examples, and applications using bipolar and MOS memory chips, as well as details relating to the interfacing of memory to the outside world, namely, your computer. Special purpose chips, such as keyboard character generators, are also discussed. The section on rf power may not interest the average home computer experimenter, but the book is nevertheless a useful acquisition.

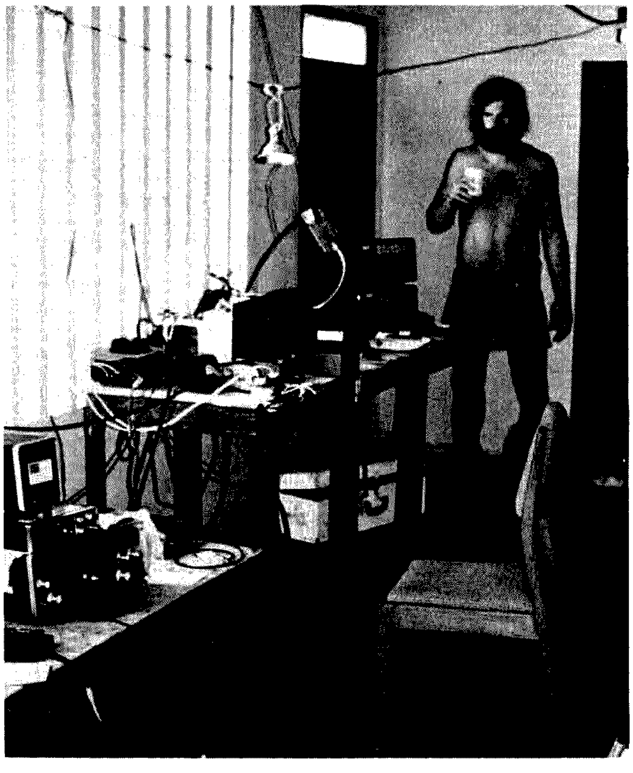
Shoot the Moon!

- - Pack Rat power

Walt Bohlman K3BPP
101 East Street
Doylestown PA 18901



The possibility of going to South America really seemed like a wild dream when toying with the idea in December, 1975. This is about the time this dream turned into a reality. With that reality came a long list of technical problems to solve. This article will describe how most of these problems were solved.

Having had W3CCX/3, the Pack Rat moonbounce station, in operation for about a year, the main technical group (W3HQT, W3HMU, and K3BPP) had a good feel of what a successful 432 moonbounce station required. These requirements are as follows:

Antenna: 26 dBi gain minimum, field repairable, easy to construct, sturdy, easy to rotate (azimuth, elevation, polarization).

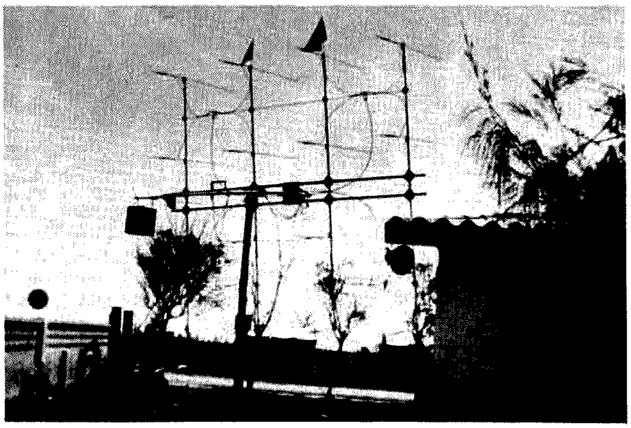
Transmitter: Straightforward design, 1 kW output without straining, stable, rugged.

Receiver: Spares, .5 kHz B.W., 1.3 dB noise figure at antenna, rf filter.

Antenna

After considering many possible approaches, the simplest and most conservative design was used. The antenna consisted of 16 K2RIW yagis fed in phase through adapter power dividers. At the TR relay (Transco-Y), the power divided equally into 4 50Ω outputs. The 4 ports each fed 10' lengths of ½" foam hard line, each of which terminated in a 4 way adapter power divider, each of which fed 4 yagis. Each yagi had an 8' length of RG214 running from its ½λ UT141 balun transformer to the power divider.

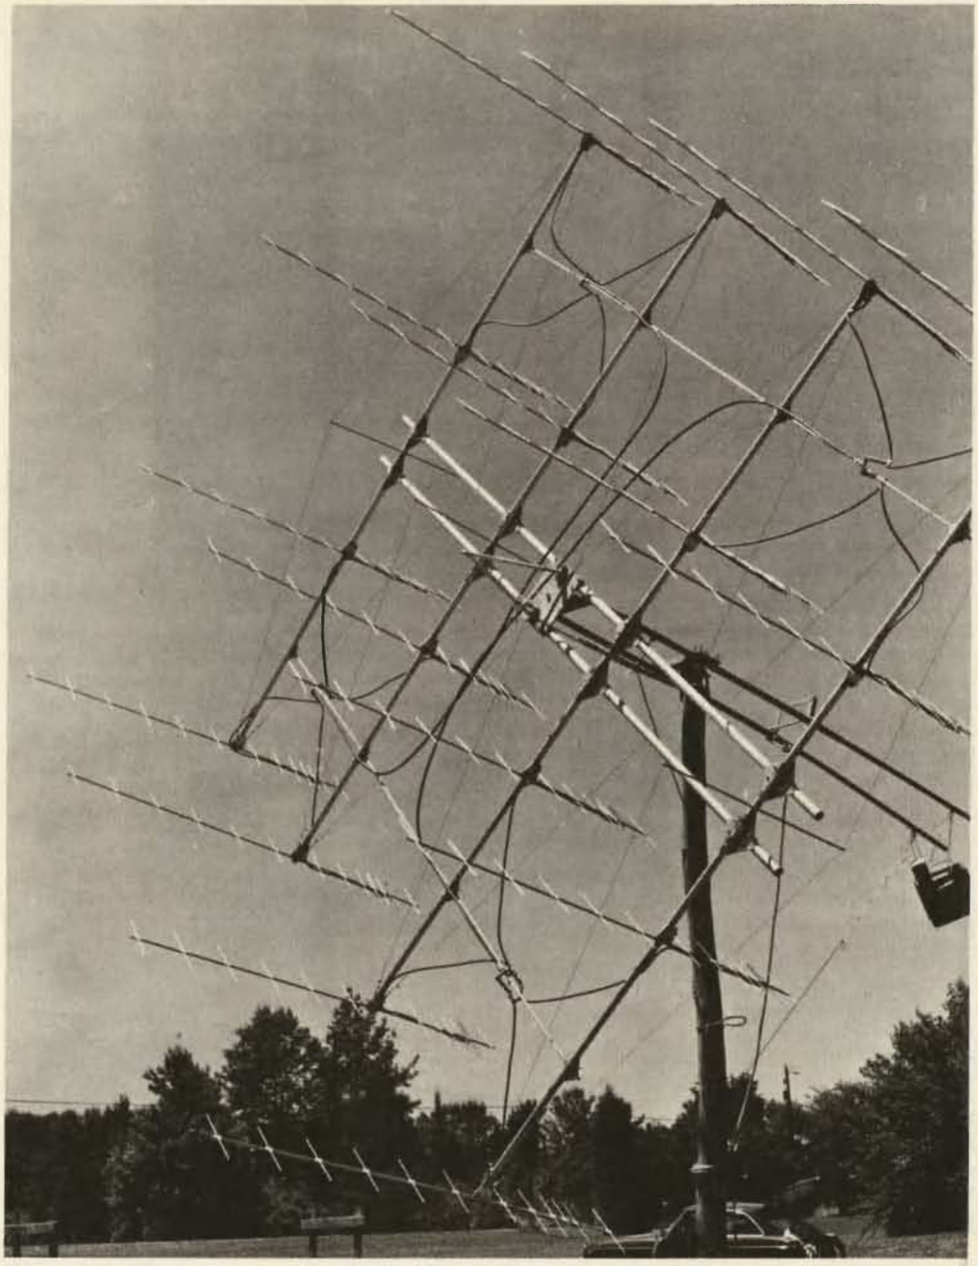
Each antenna boom split in the middle, allowing it to be packed in a small space. The 16 yagis were mounted on a double H frame made of



On location.

lengths no longer than 6'. The very careful design of this frame by W3HMU and W3HQT performed and packed quite well. The antenna spacing was optimized by K3BPP by the use of heuristic reasoning and a computer program to print out the resultant pattern. The ideal spacing worked out to 5' between antennas, thus giving a 15' x 15' array with a theoretical gain of about 29 dBi. Side by side comparison with the 20' dish gives ≈ 2 dB improvement over the dish, putting the realization gain in the proper area.

The mount was mainly the result of the cleverness of W3HQT. Very shortly into the program it was decided the polarization rotation was absolutely necessary. This was accomplished by a bearing plate extended 4' from the azimuth elevation mount. Also, since the moon would be quite high, the antenna had to point straight up (a favored position of dish owners), aligning the axis of the mounting pole with the antenna axis. This complete operation was accomplished with parallel water pipes that straddled the mounting pole in the straight up position. So, in total, the parallel pipes had the polarization bearing at one end, mount back 1/3, and a counterbalance (one of the shipping boxes) at the other end. Though a little difficult to pick the best yagi to use for boresight, the mount and antenna worked just great.



Testing in the U.S. Photo by Richard Boyle K3IGX.

Transmitter

The requirement was set for 1 kW output with no strain. This 1 kW starts to decrease rapidly when things are not just right (line voltage, exciter tuning, weak tubes, etc.). Upon evaluation of a portable transmitter generously loaned by K2UYH, it was decided to construct a new model around an 8938 grounded grid triode. This tube had performed very nicely at W3CCX/3. Having invested many hours trying to optimize the link coupled ¼ wave box cavity of the W3CCX amplifier, a new design was considered. The design was patterned after the successful K2RIW stripline kW. The amplifier was constructed and tested by W3HMU in approximately one month and worked superbly. The design consists of a ½λ triplate line with the tube at one end and a flapper tuning capacitor at the other end. Output coupling is also done with a flapper tuning capacitor at the tuning end of the line. The cathode line is quite similar in construction to the plate line. The amplifier puts out about 1200 Watts with 50 Watts of drive. The power supply is about the size and weight of a DX100. The exciter, also similar in size and weight to the power supply, consists of a conventional 220 MHz 10 Watt 6360 rig with a 4 x 150 doubler to 432. The doubler drives a conventional cylindrical coaxial cavity 4 x 250 amplifier which can put out up to 120 Watts. The exciter was designed so that the 4 x 250 amplifier could be used separately to amplify the Echo 70 for OSCAR 7 use. The exciter was self-contained with power supplies.

Receiver

Though only 40' of ½" foam hard line was used for the feedline, it was still necessary to mount the first preamp at the TR relay on the antenna. The main preamp consisted of an FMT4575 with about 1.3 dB noise fig-

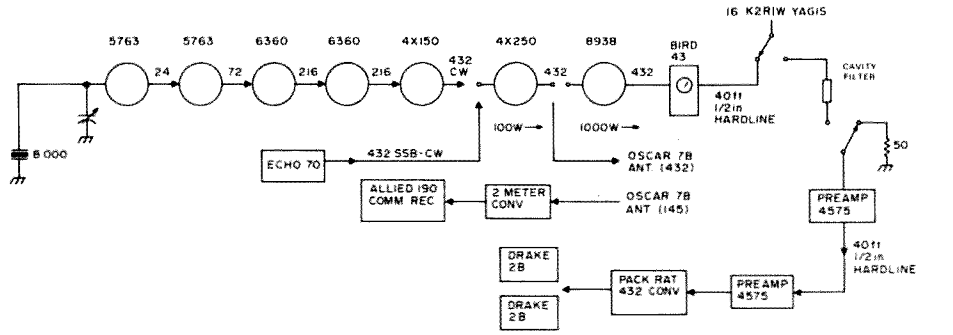


Fig. 1. Pack Rat EME OSCAR portable station, HK1TL.

ure. Between the antenna relay and the preamp, a 3" dia. λ/4 cavity filter was used. The required low loss of the filter necessitates making this a separate item and not a part of the converter.

At the end of the hard line, a 2 dB noise figure preamp was placed to override the loss of the connecting hard line. A Pack Rat converter was used into one of 2 Drake 2B receivers. One of the 2Bs was linearized and used in conjunction with a VOM for sun noise measurements. An audio line from the receiver ran directly to a cassette tape recorder for recording the history-making event. ■

Frustrating the Thieves

-- removable mobile mount

Stephen Wimmer WB0GGT
RFD 1
Lincoln NE 68502

Looking for a really easy way to mount my HR-2A in the car, I hit upon using slide mounts that are normally used for stereo tape players. For me this turned out to be a very good idea, as I am in the Navy and not at home that often. During tours in the Philippines and Italy, this setup has really worked. While I was away, my parents used my car, and since neither is licensed there was no reason to leave the rig in the car. Having had a shortwave converter in the car before I acquired the rig, I decided to make them interchangeable. That way my parents could use the SW converter when I was away.

To put the mount on my HR-2A, I had to remove the speaker. At first I used a speaker box mounted on the hump behind the gear shift lever. I doubled the hot lead and the ground lead to ensure that the rig was getting enough power. The antenna connection was left as a PL-259 since I had to use two of the connectors for the speaker leads. Later I purchased a cassette/radio, placed it in the hole for the old radio, and used the radio speaker in the dash for the rig. Ensuring that the tape player still worked, I moved it to my father's pickup. Since I was going to be driving for him for a while, I put a mount on the tape player and bought a gutter clip mount for an antenna. The mount in the truck is covered by a blank slide when not in use.

Now when I get home, all I have to do is dig the mike out of the attic, slide the rig in the car, and I'm ready to go. ■

The HR-2A in the car.

Automatic Autopatch Release

-- safer mobile operation for the troops

There's no denying the value of an autopatch on a reliable repeater. Whether it's for the "little" calls or the more important emergency calls, the autopatch is fun to operate.

All autopatches have a defined attach and release procedure. Some of them have a straightforward "easy" attach and release while others may have relatively complex access codes designed to limit use of the autopatch to "qualified" persons. The attach and release can be made as complex as desired. Generally, the release procedure is somewhat simple. If you want to streamline the use of your autopatch, you can make the release fully automatic.

To automate the release, a simple circuit is added that will generate a "disconnect" signal for the patch control logic when the called party hangs up (signaling the end of the telephone call). The circuit is based upon a fairly consistent characteristic of the phone line's polarity. The voltage across the phone line is typically 48 V when the handset is "on hook." When the handset is removed, the voltage drops to around 6 V. When the called party answers, the 6 V reverses polarity for the duration of the call. When the called party hangs up, the polarity returns to the pre-answered condition. This pattern of voltages and polarity transitions can be used to generate a patch release signal. The various levels and polarity conditions are summarized in Fig. 1.

The circuit shown in Fig. 2 is used to provide a contact closure when the called party has answered. This contact closure is then used to provide a path for charging a capacitor that in turn generates a negative pulse when the called party hangs up. Notice that there are two power supplies – a dedicated "floating" power supply for the polarity detector and the +12 V power supply for the system. The separate supply for the detector is an absolute necessity to avoid grounding one side of the phone line! A capacitor is connected across the relay coil to delay the relay pulses that may occur during the answering process. You may need to experiment with the capacitor's value to accommodate local conditions or a different relay than the one used in Fig. 2.

The output stage is simply a transistor switch that is biased on (output = .5 V). The capacitor is charged via the 1000 Ohm resistor during the answered period and then generates a short negative pulse on the base of the transistor when the called party hangs up. The negative pulse momentarily turns off the transistor causing a momentary positive pulse at the output. This pulse can be used to turn off the autopatch by simulating the normal manual turnoff character, pulse, signal, etc.

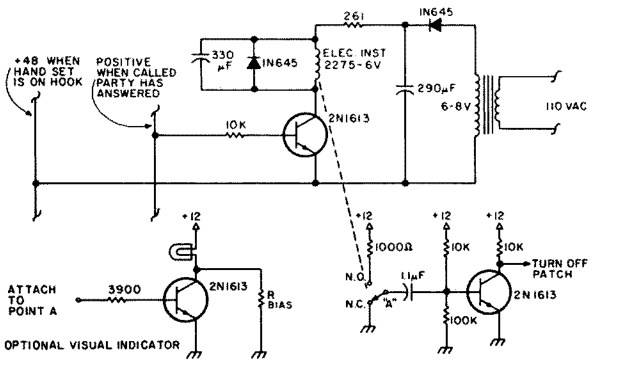

Fig. 2.

The optional visual indicator is simply a lamp driver that can be used to light a panel lamp when the called party has answered. If the repeater is already equipped with a group of status lamps, this additional lamp may be added to provide a little more operational and diagnostic information. Select the bias resistor so that the lamp filament is slightly lighted when the input to the base (Point "A") is grounded. Keeping the lamp warm will prolong the lamp's life and protect the transistor from current surges through the lamp's filament.

The polarity detector should be attached to the phone line on the "repeater side" of the relay that connects the phone line to the patch. This will eliminate any improper interaction with the phone line when the patch is not in use. Fig. 3 shows the appropriate interface. Check the phone line polarity with a voltmeter and attach the detector as illustrated in Fig. 2.

Why not add this little circuit to your autopatch? It makes using the patch a lot more convenient and saves having to reach for and dial a release command at the end of the call. The less you dial while driving, the safer you will be! ■

Bill Higgins WA2RXQ
430 Ocean Terrace
Staten Island NY 10301

Emergency 911 System

- - help for NYC

It was December 27, 1976, and Christmas gifts were still in sight in the Higgins' living room as Mike WB2EIL and Bill WA2RXQ were hurriedly rewinding a video recording of the evening news. NBC had just aired a three minute and 19 second special entitled "Helping Hams," when over the monitor of WR2ADP came WA2UTV, "Is there any control station on frequency?"

Almost before I could reply, WA2YYZ came on frequency followed by WA2JSJ, KTUAT, WA2VBJ, WA2ECI, WA2FUL, W2DME, WA2KHN, WA2HYT, and a continuous parade of well-wishers. Mike remarked that he had not heard the machine this active since 1975 when we loaned the station to the New York City Police Department for three days, following a five alarm fire in a main switching center of the New York Telephone Company. The station call then was WR2ABK, but it was the same group that was operating WR2ADP now. We reflected on how it all began and how grateful we were to the production crews at NBC, particularly to Stephanie Stern, who had worked so hard to produce the special news documentary about amateur radio.

News Center 4 began the show with Mary Merendini WA2CSM driving down a country road and talking to her harmonic, Lisa, about her day in school, when Lisa, dramatizing, remarked that she saw a burglar breaking into Mr. Jones's home. Mary, determining that the Joneses were away on vacation, proceeded to pull off the road and produce a Wilson HT with TT pad and, as the camera zoomed in over her shoulder, punched the digits 911. In response, a voice returned, "Police Department, where is the emergency?" Mary proceeded to report a burglary in progress. From there, the cameras took us to the repeater site and focused on the repeater cabinet and control circuit that Jim WA2ECP had designed and built. The cameras then took us to police headquarters where calls for emergencies are processed.

I got my chance before the camera and explained that the project implementation was delayed for more than 15 months due primarily to objections and conditions set down by the police department. I explained that it was the desire of the Radio Amateurs Repeater Association of Staten Island to assist the public and government in times of emergency, that while landslides and earthquakes get the most publicity, there are many such catastrophes in individual lives each day on a local level. Assisting with one of them is equally as important as giving aid to a foreign country.

The program ended by showing the awards the repeater group had received in the past: a letter from the FCC, an ARRL Public Service award, and a certificate of appreciation from the New York Police Department. A file film depicting the work we had done during the 1975 telephone company fire was also shown.

Due to the time limitations of television and, I suppose, the desire not to get technical with the viewing public, it was not possible to get into the why and how of our 911 system on television. However, for those of you who live in or visit New York City, here is how it works. The repeater is capable of autopatch and reverse autopatch but, as you already know, the prefix codes to activate dial tone are reserved for active members' use. It seemed to me that to have more than $2,500 worth of equipment idle, when someone had an emergency but could not raise an operator with the autopatch codes, was not good business. My first approach was to request permission from the police department to install amateur equipment at headquarters on 147.911 MHz. The equipment I suggested could be manned by police officers who hold ham tickets. The idea was turned down about four months after my first letter was sent. The police requested that all calls for emergency aid be directed through their 911 telephone system.

It seemed to me that the police did not care or want to cooperate. Some months later, while cleaning up some paperwork, I came upon that same letter. This time the words "directed through their 911 system" had a new meaning for me. I called Jim Passione WA2ECP who had built most of our control circuitry and asked him if he could modify the circuit so that unknown hams and transients could access the 911 police emergency number without knowing the dial tone access code.

The system we came up with is so simple that I am almost embarrassed to tell you how long it took to devise; anyway, here goes. A station comes on frequency (147.915) and signals 911 on a TT pad (no need to bring up dial tone). The decoder receives it and closes a relay which energizes an eight track tape recorder. Track A reports back to the caller, "Please stand by. Your call for emergency assistance is being automatically processed." Track B, simultaneously, is redialing the New York City Police emergency number 911 on an open telephone line and informing the police to stand by: "A call for emergency assistance is being automatically relayed via amateur radio station WR2ADP." Approximately 15 seconds down the line, the caller and the police are patched together. They are permitted 100 seconds of conversation and then are

automatically disconnected. There is a 30 second warning prior to disconnection which states that, "If more time is required, signal 911 again."

The repeater has been programmed to rebroadcast the US weather in order that interested parties may test their equipment: *41 activates weather and *47 disconnects. This function should discourage anonymous operators from embarrassing the amateur fraternity by falsely signaling 911 without reporting a bona fide emergency.

The police department requests that all callers, except those located in Staten Island, state the borough from which they are calling. Since the repeater is using a Staten Island trunk, all calls processed through the repeater appear on the Staten Island dispatcher's desk. They can be routed to other boroughs through the police computer switching system if they are properly identified.

Bill Higgins WA2RXQ, trustee of WR2ADP, demonstrates the "emergency autodial" to officer Andy Merendini WB2EIR. Andy now carries two HTs when on duty.

All hams are welcome and are invited to use the 911 feature in the event they encounter a situation that they believe requires police attention. I sincerely hope that calls for minor disturbances are avoided in order that the network not be overloaded both at the repeater and at an already overworked communications bureau. ■

The Downspout Vertical

-- a great 15m antenna for soda pop drinkers

Just imagine going from 21.000 to 21.450 and not having to touch the loading controls, after an initial tune-up on about 21.220! I built this one in the middle 50's, right after I received my General Class, so most of this is from memory. My reference was an article in a 1954 *QST*, "Beer Can Vertical," which was for 40 meters.

Description

I used 11 feet of rain gutter downspouting for the vertical element. Since downspouts don't come in such odd lengths, I had to use an extra piece of sheet metal wrapped around the top section to make up the difference. This was attached with sheet metal screws.

The vertical element was insulated from ground by a quart soda pop bottle. This bottle was first placed about halfway into the ground to stabilize it.

The vertical was guyed from the top with nonmetallic clothesline. At the base I used a 6 foot ground rod, and the transmission line was a long length of RG-58. I realize now that two improvements would be: several 12 foot radials and feeding the whole thing with RG-8.

Operation

My rig was a Johnson Adventurer (50 Watts input to an 807) with a wi-i-i-de range pi-network output tank (no tuner needed). This rig loaded up just fine to this vertical. I don't know what the swr was, because I didn't have an swr bridge. In fact, I don't think *anyone* did in those days, except the ARRL's laboratory! With today's "modern" 50 Ohm output transmitters, you probably will have to resort to feedline trimming or use an unbalanced tuner to get a match.

I was able to work "all over" Europe and Africa and into Asia, and I have QSLs to prove it! ■

RTTY? What's That?

- - how to get started with teletype

After doing some years of customary operating, I thought it would be fun to operate with a teleprinter – encouraged by another amateur donating a teleprinter and a lot of advice. Thinking that it would be fun to get involved with something new, I accepted; since then I have learned a lot of good information about how machines operate, how to fix them and the like.

There is a lot of information available about different printer models and basic information on how they work, along with basic operating techniques. Rather than repeat or summarize that information, this article will give a couple practical ideas to the person wanting to get started.

You really only need two things to get started – a printer and a converter (the converter both receives and generates the teleprinter tones). Rather than fussing with one of these "beginner" units, which are really not very satisfactory in operation, I thought I would start the right way the first time. There really is not a great deal of general information readily available, so one must pretty much rely on advice from others. Looking at prices and specifications, I elected to purchase the Hal ST-6 kit. There are several converters available in several price ranges; this one appeared to have the most features at the best price.

The Hal organization is excellent at getting materials out in a hurry. I received an immediate confirmation of my order with the sad information that there would be a slight delay on shipment (it developed that they were out of the power transformer). The merchandise arrived before the expected delivery day by UPS. They were nice enough to send the instruction book right away so I could get acquainted with what to do. It took about a week to put it together – the instruction book was most complete and quite necessary since the circuit boards are not marked, making it necessary to study the pictures and the diagrams to get the components in the proper holes.

Of course, when I got the unit complete it didn't work. (This problem is not confined to Hal – I have had many projects not working the first time around.) After considerable strain and a couple visits to a friend's test bench, it developed that the +12 and -12 voltages were not exactly the same + and -, and one critical place was not balancing. A paralleled resistor got the voltage to balance and everything worked fine.

One must have access to a frequency counter in assembling the Hal unit (or get it already built) since it is necessary to adjust the audio oscillator to the proper frequencies for RTTY operation and necessary to prune the tuned circuits in the receive section to get right on frequency. This takes the better part of an afternoon checking the resonance of the tuned circuits and pulling off turns from the toroids or changing capacitors to get the exact resonant frequency. It's quite necessary to have a little pile of small-value high-precision capacitors in order to get the resonance within 3 Hz of the specified frequencies. The Hal people could make some improvements in their unit by providing support for the circuit boards (they're held in by the edge connectors only) and by supplying several colors of wire instead of the generous supply of one color. It took one day to do the interior interconnecting wiring between the switches and edge connectors; I used different colors, which makes it much easier when tracing and troubleshooting.

Modifying the Heathkit SB-401 transmitter was simple. To transceive on RTTY, two contacts are jumpered to permit the unit to transmit on the RTTY position. The crystals and filter in the equipment, although ideal for 850 Hz shift, work out quite well on the almost universally used 170 Hz shift. With careful work on the carrier suppression, satisfactory operation is easily achieved by feeding the AFSK tones in the microphone jack with resultant FSK (F2) output. There is no problem using a VHF unit since AFSK is used; the signal goes in the mike jack and comes out the speaker connection.

The areas of RTTY concentration are easily found on the bands. Most operation uses 60 wpm operation and 170 Hz shift, although some 850 Hz shift is still occasionally found. A RTTY QSO is little different than an SSB QSO – the same general type of conversation takes place: name, location, equipment listing, weather report, etc. One must remember that it takes longer to say the same thing when typing, so watch that 10 minute timer. Also watch the plate ammeter since you are using a 100% duty cycle – don't exceed the plate dissipation rating of your finals. On VHF, the same information is exchanged that is heard on voice repeaters: "just testing out my new rig" along with a lot of highly technical talk of interest primarily to RTTY and computer specialists. There are RTTY repeaters that have the customary weekly net and check-in. One in this area is complete with swap shop and ARRL bulletins.

With a change of gears, one can use a communications receiver and eavesdrop on commercial transmissions (remember the FCC's secrecy rule), although much of this traffic is ASCII or encrypted.

There is a lot of press activity in Spanish at 67 wpm. Of course it helps to be able to read Spanish . . .

It also helps to be able to type for those intending to engage in 2 way teleprinter contacts. It's surprising that some teleprinter operators are rather poor typists.

At the moment my teleprinter operation is quite small-time in comparison with what many others have. Just a printer (with keyboard) and a converter. Later, when funds permit, I hope to include some tape equipment (puncher and reader) and get set up with a UART to improve the performance. Right now everything is still quite simple and satisfactory. It might be mentioned that the more sophisticated the operation, the more there is to go wrong and the more adjustments there will be.

It's a good idea to start simple and build up the more elaborate installation as your interest and funds permit. At the same time, put in good equipment that will work well, which will, in the long run, reduce your total cash outlay. Don't get a bunch of junk that will take two hours' maintenance to one hour's operating. Don't expend heavy amounts of cash on equipment that is 50 years old and getting obsolete. There is fairly good used equipment generally available; make sure it is working if you are not sure how to do the internal maintenance (or have a friend who knows how). Before starting, check the FCC rules on teleprinter operation which in general is restricted, on the low bands, to the CW portion; identification is done by CW but by your call only (you can use the letters key for dots and the blank for dashes).

You can make new friends and have a lot of fun on the teleprinter, as well as learn a lot of operating and technical savvy. ■

Do-It-Yourself Photosensitizing

-- practical PCs

Most of the contemporary articles on printed circuit fabrication begin with photosensitized board and take the reader through the various steps of exposure, development, plating, etc. One or two of the articles explain that a spray sensitizer is available, leaving the reader to assume one simply sprays clean board and is then ready to begin fabrication. This is not true. In fact, I found the most difficult part of the whole process was just coating the plain PC board, such that the resist was not floating in streamers in the developer like octopus or squid tentacles. If you've never seen this, you simply cannot sense how frustrating it is. And presensitized board usually costs several times as much as plain board.

After several frustrating times, it became obvious that I was getting the board too clean and too smooth with steel wool and scouring powder ... so clean and smooth that the paint (lacquer base resist) could not stick. A new procedure was devised and success has been mine, unfailingly, since then. I share this with you:

1. Forget the scouring powder and steel wool. Switch to #400 wet-or-dry emery paper. Work in the sink with running water and rub the board in straight, parallel strokes until you have a satin finish on the copper. Keep everything wet to prevent deep scratches. This microscopically rough surface is just what is needed for good bonding of the resist.
2. Dry the boards thoroughly.
3. Immerse them next in clean lacquer thinner. A quart purchased for this cleaning purpose can be split, with half used to remove the resist after etching ... separate containers are a must.
4. Remove the boards from the thinner, point down so they drain well.
5. Place the boards on newspaper, copper side up and dry with warm air from a hair dryer . . . ten or fifteen minutes will ensure complete removal of moisture and a slight warming of the boards.
6. Spray the boards. I do it horizontally, although the instructions on the resist say to do it vertically. I use my son's darkroom, but a yellow bug bulb over the workbench at night will do. After the spray, turn the hair dryer back on and blow warm air on the boards for another fifteen minutes, then let the whole mess dry overnight in the dark. Store in a box or wrap each board in black paper.

That's it . . . from here on, I proceed as usual. I use an ultraviolet bulb about a foot off the surface of the negative. Too much closer than this and the thickness of the negative and parallax will produce non-sharp images on the copper — the light rays will actually shine under each line on the negative and ruin your copy.

Oh yes, I use the General Cement photoresist and developer. Their numbers are 22-231 (resist spray) and 22-234 (developer). No more tentacles. ■

Making Your Own PC Boards

- - part II

Charles F. Smith
c/o 73 Magazine

This is the second and concluding part of this article. Last month, you may recall, we discussed all the "paperwork" involved in making a printed circuit board. We concluded with a finished 4 digit clock on a single-sided board. This month we will cover double-sided and multi-layer boards, as well as the manufacturing process.

To begin with, a definition of double-sided and multi-layer is appropriate. Last month a double-sided board was described as a circuit board with printed wiring on both sides. Components are placed on the side with the least amount of wiring. A multi-layer board is a board with many very thin boards laminated together. The multi-layer board described in these pages is not quite as complex as this, but works as well.

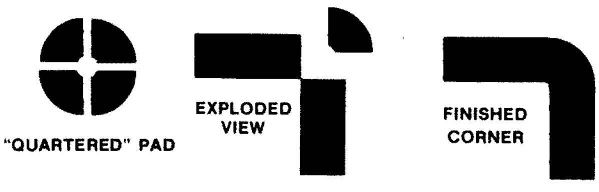

Fig. 2. Rounding the corners using cut pads.

Layout Design

Perhaps the easiest way to lay out a double-sided circuit board is to make it similar to the single-sided board. Use different colored pencils for each side (or layer, for multi-layer). Some people prefer doing each side on a separate piece of graph or tracing paper. Others use one piece of graph paper for everything. The use of two colors on one piece of graph paper will keep the two sides separate, and assure no errors caused by an overabundance of papers to keep track of.

When laying out a double-sided circuit board, it is best to keep a conductor on one side of the board. To elaborate, do not run a conductor to a component lead and then change sides. Shying away from doing this will prevent depending on side to side connections for circuit continuity.

Everything else about a double-sided board layout is basically the same as for a single-sided board.

Artwork Design (Methods)

For taping the artwork for a double-sided board, there are several different methods. The most obvious is to make separate artwork for each side. Another common method uses one sheet only containing pads and other

markings common to both sides. Use separate pieces of clear mylar for the top and bottom sides of the board. On these, place only the conductors for each side and registration marks. When a negative is made, each side or layer is placed separately above the dots. This "set" is shot together, coming out with a combination of the two. This is probably one of the best methods. Side to side registration is going to be excellent, with very little error.

A similar method is to have a print or film positive made of the pads only (one print for each side/layer), and tape directly over the photographic paper or film.

Fig. 1 shows a schematic diagram and board artwork of a power supply you may want to build. This circuit will be used here for explanation purposes.

You will notice that although the conductors are all straight and even like last month's clock, the corners have been rounded. This was done by "quartering" a donut pad twice the size of the tape used. In this case I used a ½" pad with ¼" conductors. Fig. 2 details this process.

A method worth noting was used for the top side of this board, being used as both a heat sink and a ground plane. When the artwork for the bottom side was finished, I placed another piece of mylar over it. At points where no connections between sides were to be made, I placed pads as large or larger than those on the bottom. You can see that this is exactly the opposite of what we want. Using this "overlay," I made a contact print. This gave me artwork on photographic paper for the second side. Fig. 3 should make this clear.

By the way, if you ever have to lay out a ground plane without recesses, and do not wish to use a lot of tape, use red paper. It should be a good grade of paper and be pure red. Rubylith is also a material that can be used. It is manufactured for this purpose. A good drafting supply store should have some. Black paper can also be used with good results. Because of the properties of film, sometimes red appears as a better black than black does. Strange, but true.

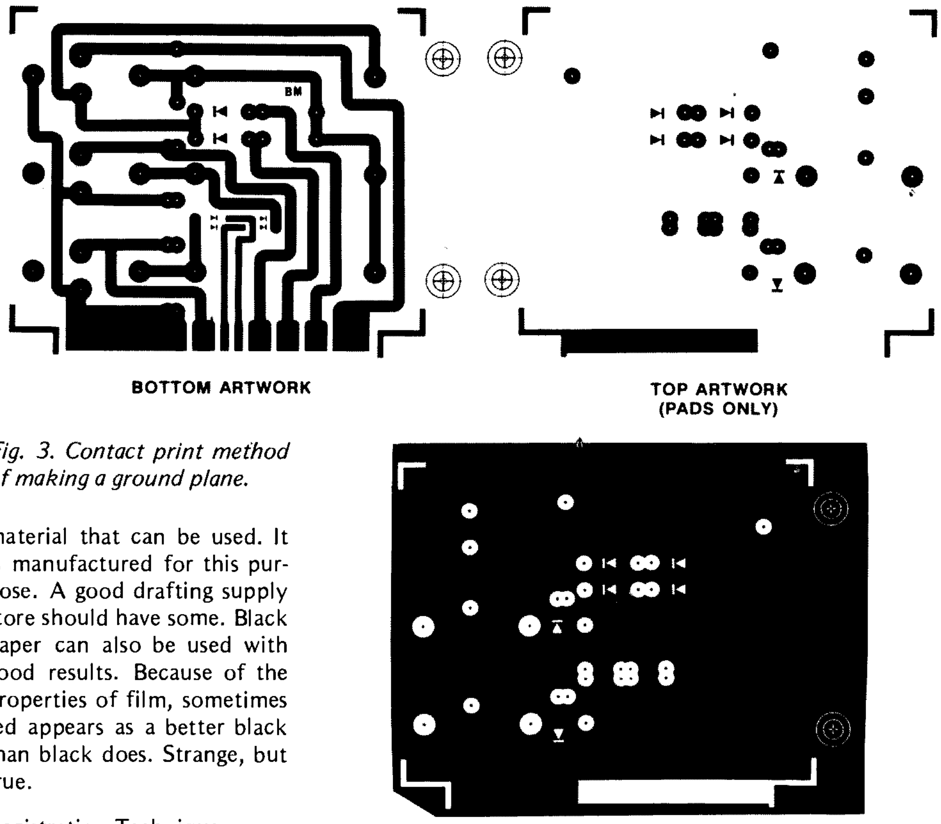

Fig. 3. Contact print method of making a ground plane.

Registration Techniques

There are many registration techniques available. Some are easier than others, but all work well. For the artwork, special preprinted "stick-ons" are available. Fig. 4 illustrates some of these, which are placed on each piece of artwork at three corners. When all layers are laid above each other, these marks should be superimposed to appear as one mark.

Pin registration is a method the graphic arts industry has been using for a long time with great success. This method involves punching a pair of holes in each piece of artwork and using small pins (usually ¼" in diameter) to hold the pieces in register. Fig. 5 shows these two methods of registration.

A relatively new method of registration for double-sided boards has been introduced by Bishop Graphics, Inc. They call it their "Red and Blue System." Instead of using black tape and pads, they suggest using red and blue. Pads and other marks that go on both sides of the board are laid down using black pads and "stick-ons." Conductors for the first side are laid down using red tape. On the same artwork, blue tape is used for conductors on the second side. This method uses only one piece of mylar, and one set of pads. This means that you have only one piece of artwork to keep track of.

When making a negative using the "Red and Blue System," special film (Panchromatic) and filters are used. A red filter is used to drop the red images and hold the blue. A blue filter is used to keep the red and drop the blue. Since there is no filter available to drop the black, mainly because you cannot, such images on the artwork are picked up on both negatives.

This method assures perfect registration every time, as well as the above mentioned benefits.

Manufacturing

Now that you have negatives for the circuit board you want to make, you are ready to do some home manufacturing. You are going to need some blank circuit boards and several types of chemicals. Each of these will be discussed separately.

The type of circuit board you use will depend upon the type of project involved, and

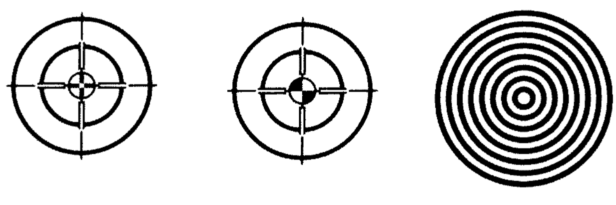

Fig. 4. Typical "stick-ons" used for registering artwork. The concentric circles are used on multi-layer board artwork.

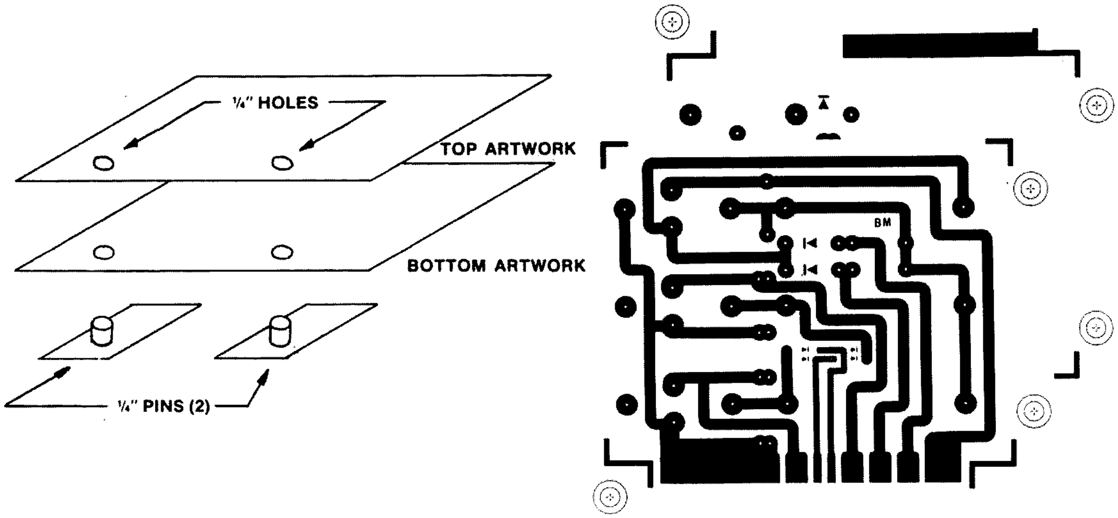

Fig. 5. Methods of artwork registration.

your choice of supply. Obviously, if one type of board is unavailable, you will have to use what is available.

The most popular types of circuit boards are glass epoxy and paper phenolic. Glass epoxy is a good board for everything, but especially for high frequency circuits and critical applications. Its leakage resistance is very high and its stability is good. It is also able to withstand harsh environmental conditions reasonably well. Paper phenolic is satisfactory for most applications, but G-10 glass epoxy is usually better.

Circuit boards come with many different "properties." Thicknesses range from 1/32" to 1/4" and beyond. Most common is 1/16". The copperclad comes in 1 oz., 2 oz., and 3 oz. thicknesses. Here, 2 oz. is most favored.

The Resist

The resist is a chemical placed on the board in places you want a copper pattern. During etching, it resists the acid and protects the foil pattern beneath it.

Resist is available in many forms. Almost any substance that can withstand heat and the etchant may be used. For the purposes of this article we will be using General Cement's "Etch Resist Sensitizer" (cat. nos. 22-230 and 22-233). This is similar to Kodak's KPR photo resist and comes in an aerosol can. KPR can be used with the same results.

The developer for this type of photo resist is either GC's "Developing Solution" (no. 22-234) or Kodak's "Photo Resist Developer."

The Etchant

After the board has been "printed," it must be etched. Etching removes all unwanted copper, leaving only the foil pattern. Different types of etchant include ferric chloride, ammonium persulfate, and cupric chloride. Ferric chloride ($FeCl_3$), available in both powdered and liquid form, will be used here. Radio Shack stocks one pint bottles of pre-mixed ferric chloride (stock no. 276-1535).

Cleaning the Board

Cut a piece of circuit board slightly larger than your finished board will be. Before you make the board, you are going to have to clean it. Unless you have commercial chemical degreasing facilities handy, you are going to have to clean it by hand. I have found two out of many methods to be very good when it is necessary to do this.

Washing a circuit board with dishwashing soap is done like this: Using warm water and a pad of Scotchbrite, lightly scrub the board to remove oils, oxides, and other unwanted residues. Rinse with water. If the board is clean, the water will not stick to the copper. Be careful, though, as water will not stick to an oily board either. Unfortunately, neither will the resist. Do not dry the wet board with a towel or cloth. Let it dry naturally to prevent any oils or foreign matters from sticking to it.

The other method is a little easier. Use fine steel wool and clean the board with this. Be careful not to touch the clean areas of the board with your fingers. As clean and dry as they may seem, your fingers will deposit oil onto the board. This will cause oxidization and prevent the resist from adhering properly.

Resist Application

When the board is completely dry, it is ready to be sprayed with photo resist. Lean the board against a wall with the foil side facing toward you.

Shake up the can of resist to mix the chemicals well. Apply a thin layer to the board by holding the can about ten inches away and spraying horizontally from the bottom to the top of the board. Best results will be obtained by spraying a continuous spray without removing pressure from the nozzle until you are finished.

To sensitize a double-sided board, spray the first side as before. Handling only by the edges, turn the board around and lean it with the coated side facing the wall. Spray the second side and let the board dry in a vertical position.

After the board has been completely coated with an even layer of resist, set it down so it is lying flat. It normally takes at least an hour for resist to dry, but the process may be sped up by

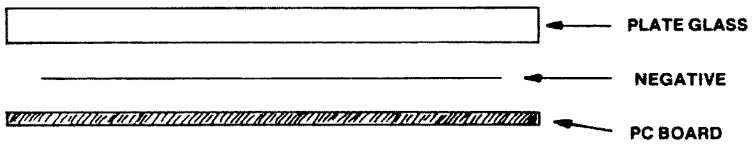

Fig. 6. Simple method of exposing the sensitized board.

Curing Mobile Noise Miseries

- - particularly on 80 and 160

My car had been away for some time for repair after an accident. When I got it back, I was not surprised to find the suppression was much poorer than it had been before.

I began checking everything: the ignition leads, the distributor suppression, the bonding of the exhaust pipe, etc., and could find no fault.

Then a curious thing happened. I had an 80 meter QSO and complained about a whine which was causing considerable QRM all over the 80 meter band on reception. I could not understand this, drove home and checked the 80 meter band for the whine on the fixed station. No unusual QRM was heard on the fixed station receiver. I had parked the car under the fixed station antenna and went back to the car and switched on the mobile rig. There was the whine all over the 80 meter band again. I ran back to the fixed station. Now I could hear the whine on the fixed station receiver also. After listening for a time, I went to the car and switched off to save the battery and decided to monitor from the fixed station. But, on returning to the fixed station, the whine was gone!

Could it be that the mobile was generating this whine itself even on receive? I switched it on again, and the whine appeared on both fixed and mobile stations.

After repeating this a few times, I was satisfied that the mobile station was definitely generating the whine, which was picked up not only by its own receiver, but radiating enough to be picked up on the fixed station if the two were close enough.

I was really confused, as the whine was not a constant note but seemed to fluctuate rhythmically — somewhat like a jammer.

I rang up a good friend of mine, G8KW (of K W Electronics), who is very knowledgeable and has much experience. He had experienced this phenomenon, but only on 80 and 160 meters.

He suggested that the whine came from the transistor oscillators in the power supply. But why did it fluctuate rhythmically? He suggested it was beating with some other oscillator in the transceiver which caused the fluctuation.

He suggested that either the antenna was not resonant at the operating frequency or else I had a bad connection on the outer braid of the coaxial cable.

I doubted whether it could be the non-resonant antenna, as I had most carefully resonated it and had had good reports when I was transmitting from the mobile on 80 meters. It was only on receive that the trouble arose.

So I took my ohmmeter, which is calibrated down to 1/10 Ohm and on which I can easily interpolate to 1/20 Ohm, and began testing: chassis of the rig to rear bumper, 0.15 Ohm; chassis of rig to engine, 0.15 Ohm; chassis of rig to headlamps, 0.2 Ohm; and so on. Nowhere was the resistance over 0.25 Ohms. Then I broke the connection of the coax from the rig to the antenna base. The center conductor showed a resistance 0.1 Ohm. I reconnected the coax at the rig, but left the coax disconnected at the antenna base, and tested from the outer of the coax cable at the antenna base end to the chassis of the rig – 3 Ohms!

Note that the beautifully low resistance of 0.15 or 0.2 Ohms from the chassis of the rig to the car was through the car, due to good bonding, and that explained the strong signal on transmission. It was not until I had disconnected the coaxial feed line that I found the high resistance.

I discussed this with my friend and we were at first inclined to believe that since it was a big car and a fairly long coaxial feed line, this might be possible. It was hard to believe that the outer braid of the coaxial cable could have a higher resistance than the inner conductor.

So the tests went on . . .

The coaxial cable was broken at various points to insert an swr bridge near the rig and also to insert a loading inductance near the antenna for fine adjustment on 80 meters. These are joined by standard coax connectors.

We found slightly corroded connectors here and there and reduced the resistance from 3 to 2½ Ohms. But the 2½ Ohms resolutely remained.

Then we found one more connector we had overlooked. That really was corroded badly, and the outer conductor was badly corroded too.

We cut out the bad parts, made up brand new connectors, and the resistance – end to end – was 0.15 Ohms including all the connectors.

Now we tested again. The suppression now was superb – as good as it had ever been. The whine on 80 meters was gone.

One cannot overemphasize the vital importance of really low resistances everywhere on a mobile installation. For suppression purposes the feed line, both outer and inner, *must* be really good and very low resistance. For a good radiated signal the car must be really well bonded, and this helps suppression also.

A really low resistance on all leads in the car is vital, and a means of measuring low resistance – by that I mean down to 1/10 Ohm – is essential. ■

Dr. Atenogenes Blanco Malabet HK1BYM
Apartedo Aereo 15-020
Barranquilla, Colombia

More on HKITL

- - Colombian views

It has been about a year since the Mount Airy VHF Radio Club (the Pack Rats) started planning for the Colombian moonbounce expedition, HK1TL. I was recently reviewing all of the articles written about this successful 432 MHz moonbounce project in South America, when it occurred to me that something was lacking. With all the publicity afforded this project by the radio press, and with the technical and descriptive articles which have been published, still missing was a description of what this project meant to our Colombian hosts. We Pack Rats knew how they felt, but it would not be proper for us to tell their story. So, I asked Dr. Atenogenes Blanco HKIBYM, the project's Colombian coordinator, to write of his impressions. The following article is the result. I think that Ate has conveyed in his article all the emotion that exists. – Elliott T. Weisman K3JJZ.

My first encounter with the South American moonbounce project occurred when I received a letter from Sam Martinez WB3AFY/HK1CWB, a fellow Colombian who now lives in the States at Baltimore, Maryland. Sam informed me about the Mount Airy VHF Radio Club's DXpedition plans and asked if I could coordinate the Colombian end of the project. I didn't know the first thing about moonbounce, but here was a request from a fellow Colombian which had the potential of providing international recognition for my city and country. I had no doubt that my answer would be in the affirmative, since I was told that the planned operation would be the first of its kind on the continent of South America and the request came from a fellow ham and Colombian. However, I did have doubts about the capabilities of the Mount Airy VHF Radio Club (the Pack Rats) and the probability of success of such an ambitious project. It was sure to be a very difficult – if not a crazy – undertaking.

I soon saw that my contribution would be in translating what the North Americans wanted to do into the Colombian way of doing things. Every country's customs and governmental procedures are different, and such an unusual project would no doubt create special problems in licensing, customs, immigration, and so forth. So I responded to Sam that I would do whatever they asked of me to the best of my ability. Here I was discussing a difficult project with a group more than 1000 miles away who were either very capable or very crazy. I really didn't know, but it made no difference – we were going to be a part of the project.

A special meeting of our AREA 2 radio club was held by the president, Juan Navarro HK1JJ. The word "AREA" stands for Association Radio Experimentadores Afficianados, and the 2 for 2 meters (the band in which we are primarily interested). We are a group of a dozen or so hams from the Barranquilla, Colombia, area who like to build and operate 2 meter repeaters and mobile and base stations. Our ambition was to one day combine forces with the Defensa Civil Columbiana (you should say Civil Defense), in order to provide a communications system which could be used in times of emergency. The AREA 2 radio club was responsive to the moonbounce project and volunteered to serve as the sponsoring organization. You see, a DXpedition to Colombia requires both local sponsorship and participation in order to be licensed and approved by the Ministerio de Communicaciones (Colombia FCC).

The problem areas identified for action at that first meeting included licensing, customs, transportation of both people and equipment, and the location for the moonbounce station and lodgings for our expected guests. The most difficult problem would be the customs arrangements.

We began our preparations in February, 1976, for the August operation. I informed Elliott Weisman K3JJZ, the Pack Rat moonbounce project leader, of what documents were necessary for the license and customs. They wrote a beautiful letter to the Ministerio, but when I checked with the head office in Bogota, I found that it had not been received in the correct department. So I flew to Bogota to meet directly with the Ministerio of Communications. Here I was lucky. The counselor to the minister is a young lady lawyer who graduated from the same university at which I studied dentistry. I showed her our official request and some background information reprinted from *73 Magazine* and the Philadelphia *Bulletin*. She issued our special call letters, HKITL, for Tierra-

Luna (earth-moon in English), and gave me an official letter to present to the customs officials. Many letters and documents were necessary for customs in order to bring in such a large amount of complicated radio equipment without having to pay duty. After a mountain of correspondence with the Colombian customs, I was at last beginning to believe that this problem was solved.

The site for the expedition station was selected to be a family beach house on the Caribbean coast about 18 miles from Barranquilla, with a horizon-to-horizon view of the August moon. This is in an isolated area serviced by an experimental power station. I visited the superintendent of the station, a relative, who assured me that there would be adequate electrical power and no problems. I also located some emergency generators for backup. Various ladders, poles and other equipment were located and readied.

Transportation in our country is mostly by bus. Few people own private automobiles, because the cost of even a Renault 6 is about 10,000 American dollars. The AREA 2 members volunteered to drive their cars for our guests' transportation. In addition, I made contact with the chief of the Defensa Civil in our area – which proved to be to our future mutual benefit. He would provide civil defense trucks and civil defense guards for the expedition.

The AREA 2 group was hard at work on our new 2 meter repeater, which we hoped to have ready in time for the expedition. We needed some special parts to complete this project. Our new friends, the Pack Rats, were able to obtain them from VHF Engineering and send them to us. This new repeater is located at 11,000 feet above sea level on a shoulder of Cristobal De Colon Mountain in the Sierra Nevada, about 80 miles from Barranquilla. It operates under an AREA 2 club callsign, HK1EE, on the frequencies 16-76. It covers several thousand square miles from this high location. We used this repeater extensively for liaison during the moonbounce project.

A few days before our guests were to arrive, a problem with their airline tickets came up. Sam's XYL, Rosalba, had arrived in advance with a check to purchase their tickets from Aerocondor Airlines; however, the prices had gone up and the check was thus too small. The group was coming from Philadelphia to Miami on Eastern Airlines, connecting with an Aerocondor flight to Barranquilla. Both airfares had increased. Aerocondor agreed to keep their price as originally quoted. Sheila HK1CWD underwrote the extra cost until the group could arrive and reimburse her. Another problem solved.

Our Pack Rat guests arrived early on the morning of July 26, 1976. There were 9 of them: Elliott K3JJZ and his wife, Lorraine Bolmar WB3AOP/HK1AMW, Sam WB3AFY, Tony W3HMU and his wife Jan, Walt K3BPP, Bill W3HQT, and Danny WA3NFV – along with 1370 pounds of equipment. Even with all the preparations and documents, it still took us two hours to clear the equipment through customs. That doesn't seem too bad, however, when you consider that it usually takes 15 days. We loaded our guests and their equipment into several cars and small trucks. The first stop was for several press conferences. Our guests were prevented from wilting under the hot Colombian sun by several bottles each of our good local beer. Finally, late in the afternoon, we arrived at the beach house QTH.

I must tell you of my impressions of these Pack Rats. These people should be millionaires back in the States, if they work as hard at their occupations as they do at moonbounce. It was very rare when they got more than three hours of sleep a night. If they weren't working radio contacts, they were either repairing something or making preparations for the next day's operation. They were always smiling (except when the power went out) and, even more important, they were always willing to take time to explain, to teach, or to make friends.

The site was not a Shangri-La, but Rosalba did a great job of making it home for our visitors. The AREA 2 gang contributed daily goodies of beer, soda, rum, and homemade cakes. In addition, there is this enormous ocean out front to help moderate the August heat and also provide diversion during power outages. These power problems developed because of the strong afternoon breezes which kept knocking out the electricity. The moonbounce crew located the troublespot. I had three generators which were either too small or too poorly regulated to be of value. The Defensa Civil finally came up with one which would do the job, but by then the problem was cured. However, now we knew where to get one for emergency radio operations. I kept our friends calm by telling them a "proverb" I made up, "The disappointment of a power failure is best soothed by a swim in the ocean." It worked.

We found a combination of English and Spanish and "ham" to work very well. The universal language of amateur radio was equal to all occasions. The success of the expedition has been reported elsewhere. In all, fifteen moonbounce contacts were made with eight countries and 70 QSOs on Oscar 7B were made with five countries. We celebrated at a banquet hosted by the AREA 2 radio club, where we presented our Pack Rat friends with a plaque commemorating the first South American moonbounce contacts. We also elected the Mount Airy VHF Radio Club a brother organization. Afterwards, we found out during an all-night soiree that our North American friends were fully equal to the challenge of a Colombian fiesta.

The benefits of our joint efforts have gone well beyond the moonbounce project. The amateurs and the Defensa Civil have become closer, and are now working on a system of cooperation for times of emergency, when we will provide radio communications through a system of repeaters covering the whole north coast of Colombia. With the AREA 2 club, the radio club of Atlantico, and the Cartegena radio club, HK1BAR and HK1AAH are also working on Oscar systems. Maybe someday soon we will QSO with our friends via the satellite.

A dividend of our project came recently and unexpectedly. A very sick Colombian lady needed a medicine manufactured by the drug company where K3JJZ works. I spoke to Elliott via 20 meters, and he made arrangements for the drug to be flown to Colombia in time to save this lady and her unborn child. This was made possible by the friendship resulting from the project.

Finally, as I wrote this, I flipped through my file of correspondence, looked through the photographs we took, and re-read the newspaper articles that were written. I felt again the excitement of those golden moments we shared together and the warm glow of the friendships we made. The only thing I can say is, "Come back, Pack Rats, we have a Mars bounce waiting for us!" ■

I/O EDITORIAL

KILOBAUD VS 73

One of the tougher decisions to live with was the one whereby we would not print the same articles in both *73* and *Kilobaud*. Every now and then an article comes in that is a natural for *both* magazines and I have to decide where it will go . . . knowing that I am really shortchanging the readers of the other magazine when I make the decision.

For instance, take a beautifully detailed article on keyboards which thoroughly covers every kind of keyboard that you might run into . . . the debouncing circuits . . . gating circuits . . . coding vagaries. Obviously the computer nuts have to have that data . . . and so do you. It's going in *Kilobaud*, so it comes down to this . . . either you subscribe to both magazines (a move I endorse), you write to me and convince me that some articles should be in both magazines . . . or you just make do without some of the cream.

What do you think?

HOW'S KILOBAUD DOING?

The response has been most gratifying. Apparently there was a gigantic need for a magazine for beginning computer people . . . people who know as little as I do about them. I've made sure that the articles are simple enough so that I'm able to understand them – and this has hit the jackpot.

Kilobaud, like *73*, is *packed* with interesting articles. I'm getting a lot of the same comments on it that I do on *73* . . . particularly that while the readers do get other magazines, it only takes them a short while to read the others and it takes days to read *Kilobaud* because there is so much of interest in it.

The first print run of 25,000 copies of the first issue of *Kilobaud* sold out and we're printing up some more to try to keep up with the demand. If we can keep up the momentum, *Kilobaud* will be the largest circulation magazine in the hobby computer field by its fifth issue . . . all the result of our publishing a massive amount of fantastic and easy-to-understand articles.

News? We need input, and one of the best sources is the club newsletter. Got one? We reiterate our longstanding offer of a free subscription to 73 *or* Kilobaud *in exchange for a spot on your ham or computer club newsletter mailing list. Deal?*

HAMS VS COMPUTERS

Computer exhibits at hamfests and conventions continue to be the most mobbed, as more and more hams discover that a microprocessor is just a newfangled IC with which they are going to have to get familiar. The longer you put off getting into this fascinating part of modern electronics, the more alienated you may find yourself. Try to remember, if you're old enough, how a sizable group of hams tried to ignore solid state, complete with *QST* as their flagship.

The fact that there are about 50,000 people into hobby computing should be an inkling that it is fun. You don't gather up that many fish in a two year period without awfully attractive bait.

One interesting part of this is that while it doesn't hurt to understand how computers work to play with them, it is by no means mandatory. You'll find that only a small percentage of the hobbyists know as much about their systems as you think they do. This is one of the reasons that *Kilobaud* has been such a hit . . . it doesn't assume a lot of knowledge on the part of the reader.

It's quite possible to either buy an assembled computerette or put together a kit and have a ball with it without ever knowing how the blamed thing works. The "appliance operator" rides again. I tend to think in terms of "black box" users . . . and I think that this is going to be the direction of the major growth in microcomputers.

More and more we will be seeing interfaces between these computers and ham gear . . . with television sets . . . with the new video games . . . and all we'll have to be able to do is load programs and have fun. I think most of us will get accustomed to writing our own programs for special jobs we want to do . . . and get so we can read a program in BASIC just as we do a schematic diagram. Kids under ten years old can do it.

Be sure to get to Atlanta in June (18-19) and check out the computer exhibits . . . there will be a lot of them. Those of you who can get to Seattle will have a choice bunch of computer exhibits to see also . . . last weekend in July. I'll be at both . . . be talking on the programs . . . and answer as many questions as I can.

ATLANTA JUNE 18-19

This is the biggest convention in the country outside of Dayton . . . and will be dragging 'em in from all over the South. Chaz Cone (of Navassa Island fame) is the fearless leader on this one and he's rounded up some nice prizes for those who still think there is a free lunch. The biggy is a KDK-144 synthesized rig, a Larsen antenna and a new car to go with the combo . . . talk about thinking *big!*

That's the good part . . . but then nothing is ever perfect, so the fact that I'll be speaking every now and then needn't be held against the effort. If there is any interest, I'll give some details and answer questions on how to get your own business started in your spare time making ham gear (how to become rich). If everyone is so used to being poor . . . or is rich already . . . then I'll give some inspiring words on the WARC debacle . . . a message of cheer to ARRL fanatics . . . how to write articles for *73* and get famous . . . or stuff like that.

It is high time to pencil in that weekend for some fun . . . and Atlanta is a ball! Between Underground Atlanta (I wouldn't miss it!), Stone Mountain (ditto), Aunt Fanny's (wow, what food!), there is so much to do and see around Atlanta that it is worth the trip without any convention.

The convention will have some of the top speaking talent . . . great prizes . . . possibly more exhibits than Dayton . . . including the latest in ham-oriented computer stuff . . . and the friendliest bunch of hams you'll run into anywhere.

HELP!

A glance at any issue of *Kilobaud* will indicate an amazing number of companies providing microcomputer kits, peripherals, and software. The *KB* laboratory is obtaining as much of this hardware as possible, for evaluation purposes as well as for production of software cassettes that you will be seeing at your favorite computer emporium. We have reached the point where our computer specialists could spend their entire day building, testing, and debugging micro systems. Of course, this is not the best situation when there is so much else to do, like getting a chance to do some skiing or snowmobiling every once in awhile. We are looking for a digital technician to help with our microprocessor overload. This individual must be up on digital construction techniques, and familiar with TTL and CMOS. Practical experience with microprocessors is a must considering the nature of the job! Also, feel free to include in your resumé any experience you may have had in interfacing peripherals, such as floppy disks, terminals, or cassettes, to a microprocessor system. The *KB* laboratory has the scopes and test equipment you will need to get our microprocessors going. (Software knowledge sure would help, since hardware expertise gets you exactly half-way in the computer business!) Give it some thought. If you are interested in coming to New Hampshire (no gas shortage here), let us know, addressing the above points as completely as possible. Sell yourself. We plan on reading more than one resumé, so please – no hand-written jobs. After reading every sort of scrawl that gets sent to *KB* for six hours, imagine what sort of reception your hand-written resumé will receive at 4 pm. Please mark your envelope with a bold "RESUME," as our mail sorters also put in a full day's work . . .

An Intelligent RTTY Station

- - the ST-6 TU and 8080 micro

Louis I. Hutton K7YZZ
12235 SE 62nd St.
Bellevue WA 98006

One of the difficulties encountered when using microcomputers is the problem of finding out exactly

The K7YZZ computerized station.

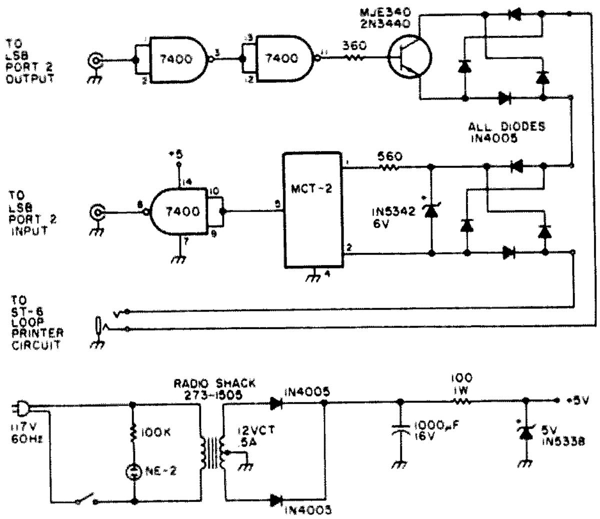

Fig. 1. The RTTY interface unit schematic diagram.

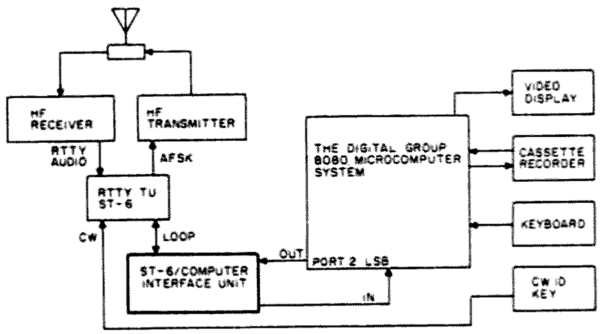

Fig. 2. System block diagram illustrating how adapter is used to interface the ST-6 to computer.

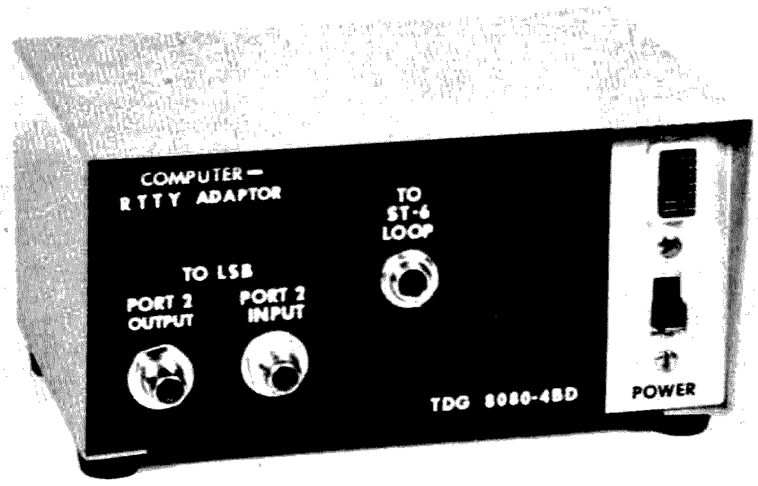
how to use the machine for something other than playing games and doing simple math problems. Since I built my machine[1] with the idea of using it in my ham shack, I decided that after several months of playing and writing games, I would move it from the living room down to the ham shack and see what could be done to get the thing to talk to my transmitter and listen to my receiver on RTTY and CW. This article will describe my efforts in connecting it to my ST-6 RTTY TU and programming the computer to act as a "Model 28 KSR."

I ordered a copy of the HAM-1 audio cassette program for the 8080 system from The Digital Group Software Systems[2], and when it arrived a few days later, I studied the written material that came with the tape recording. The HAM-1 cassette enables the operator to program the computer for operation in two modes, one as a TTY keyboard and video terminal (TTY-TVT), and the other as a CW keyboard with message storage buffers and a CW reader with the characters appearing on the video display (CW-TVT).

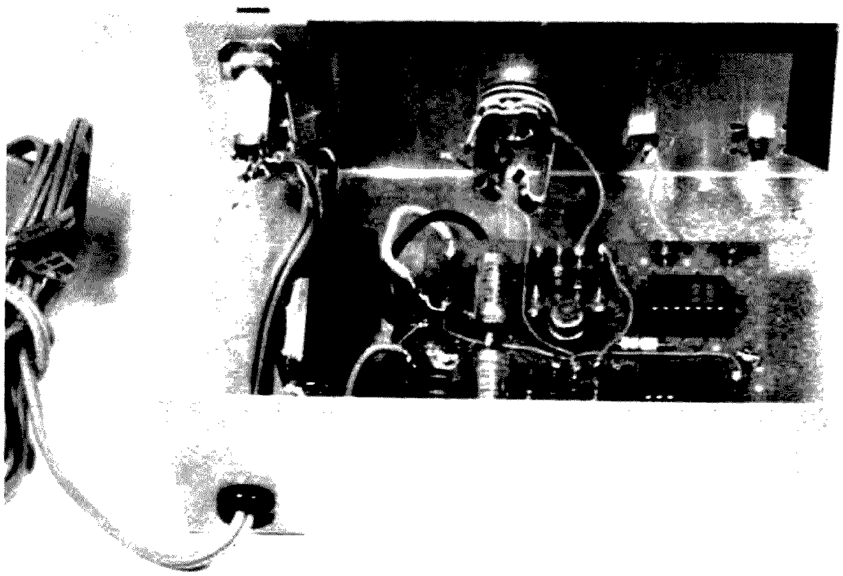
In the instructions, I also found information on how to modify the HAM-1 program to connect the output of the TTY data to port 2 or 3 input and output terminals. I modified the program on my machine to use the least significant bit terminal of port 2 and made a new copy of the program using the "Cassette Write" function. I plan to use the port 3 terminals for a CW system. TTY output signals appearing at these selected ports are in a Baudot coded, serial bit stream, at TTL logic levels. That is, a MARK as plus 5 volts and a SPACE as 0 volts. TTY speeds may be selected from keyboard commands for 60, 66, or 100 wpm. Once the program had been modified as suggested in the HAM-1 data package, the next step was to determine how to connect it to my ST-6 TU to receive and send RTTY.



The completed RTTY adapter.

The ST-6/Microcomputer RTTY Interface Unit

The RTTY interface unit shown in the schematic diagram of Fig. 1 performs two functions. The first is to take



Interior view of RTTY adapter.

```
H011 L140   303 320 011
H011 L320   376 240 302 340 011 315 372 000
            076 004 315 242 011 303 135 011
            376 215 302 145 011 026 002 076
            010 315 242 011 025 302 347 011
            076 002 315 242 011 303 135 011
```

Fig. 3.

the incoming TTY signals from the ST-6 TU loop circuit and isolate them from the low voltage TTL logic circuits in the MCT-2. The TTL level Baudot signal from the MCT-2 optical isolator is buffered and inverted in the 7400 and is sent to the least significant bit terminal of port 2 input. This Baudot signal is processed in the microcomputer and displayed on the video monitor.

The second function of the RTTY interface unit is to receive keyboard generated, Baudot encoded, TTL logic level signals from the computer and feed them to the dc loop keyer transistor stage of the RTTY interface unit. The keyer transistor keys the ST-6 loop through the diode bridge. The ST-6 converts the loop signals to AFSK tones for transmission to the radio transmitter audio input. No loop dc supply is required for this unit, as it is supplied by the ST-6. Diode bridges are used to keep from having to worry about loop supply dc polarity damaging the circuit.

Operation

With the RTTY interface unit connected between the ST-6 and port 2 of the computer as shown in the block diagram of Fig. 2, the modified HAM-1 tape is loaded into the computer. A RTTY signal (60 speed, narrow shift) is tuned in on the receiver and ST-6 TU. A 7-1-1 is keyed on the computer keyboard to tell the computer to set the speed at 60 wpm, receive mode, in upper case letters. The resulting decoded Baudot signals should begin appearing on the video monitor beginning in the upper left hand corner of the screen.

To transmit the TTY signal, the RESET key is depressed, and when the monitor program appears an instant later, the 8 key is depressed. This calls up the computer in the TTY keyboard mode. The ST-6 TU is switched to the send mode and the transmitter is keyed. Typing on the computer keyboard will now send AFSK signals to the transmitter.

Modifications to the HAM-1 Program

During the testing of the HAM-1 program, it was determined that there was no method of sending the carriage return (CR) or line feed (LF) functions that are required when you are sending to a station equipped with only a mechanical TTY machine. This problem was brought to the attention of The Digital Group and the modifications shown in Fig. 3 were developed for the HAM-1 tape program. The listing will provide two carriage return and one line feed signal when the RETURN key is depressed on the keyboard.

Conclusions

For those who have an ST-6 or similar type RTTY TU, this little interface unit may be used to connect the microcomputer to the TU for computer generated Baudot RTTY communication. The next article will cover a low cost RTTY TU that is designed for direct connection to the computer and ham station equipment. ■

Interrupts Explained!

-- getting a micro's attention

Robert Leyland ZL1TRM
113 Orakei Rd.
Auckland 5, New Zealand

For most microprocessor owners, the subject of interrupts is avoided like the plague. This should not be so. Interrupts are among some of the most useful options available to the microprocessor owner.

The very nature of interrupts (i.e., their unpredictability) accounts for the fear and mistrust of using them. My *Dictionary of Electronics* defines an interruption as: "In microcomputers: a halting of the main program followed by the starting of an interrupt subroutine, or returning from the subroutine to the main program."

Either way, it does not make much sense until you realize just how useful an interrupt is.

An interrupt is virtually a "Hey you" followed by an "I want this done now . . ." The loudness of the "Hey you" indicates its priority if more than one arrives at once. When an interrupt occurs, you drop whatever you are doing and go to the interrupter to see what he/she/it wants, and when this is completed, you are free to return to what you left.

A more useful analogy when considering interrupts is the telephone. Picture yourself sitting with some friends chatting (main program) when the telephone rings (an interrupt). You excuse yourself and go to answer the telephone (jump to the interrupt location). When you pick up the receiver, the telephone becomes engaged (interrupts are disabled), and you talk to the person calling (execute the interrupt subroutine). When you have finished, you hang up the receiver (enable interrupts) and resume the conversation with your friends (return from interrupt).

Priority and multiple interrupts can also be considered in this fashion, such as the doorbell ringing (high priority), the telephone (low priority, let the XYL answer it), or a call on your ham gear (high priority to you, but low to the XYL). The analogy can be carried much further.

In the following description, I have tried to be as general as possible, because with the wide variety of chips, each with its own unique interrupt system, the details are best left up to the programming manual for that particular chip.

However, the basic rules of interrupts are common to all systems. Interrupts were developed to handle a particular type of situation. This situation is when an external device, at some unpredictable moment, requires that the computer do something immediately.

When an interrupt occurs, the CPU (Central Processing Unit) must literally drop everything, but it must remember where it was before the interrupt occurred. To do this in most systems, all of the contents of the registers are pushed onto the stack (an area of memory or other hardware storage) before the CPU jumps to the interrupt location (the interrupt subroutine). Then the CPU will perform the subroutine at the interrupt location. During this time, the CPU does not want to be interrupted again and, for this reason, most microprocessors have a Disable Interrupts instruction (e.g., DI, hex F3 on the 8080A and SEI, hex 0F on the M6800) which allows the CPU to ignore any "Hey you" no matter how loud, while it performs the current interrupt subroutine.

Systems of interrupts are generally unique to the chip and/or the machine's implementation, but generally there are three main categories:

Single Line Interrupts:

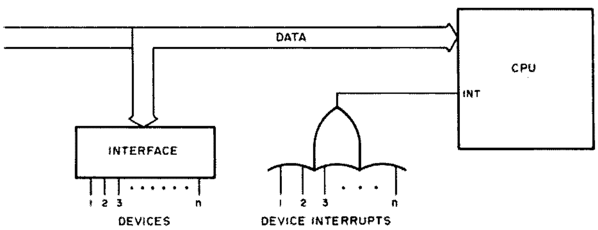

Fig. 1. Single line interrupts.

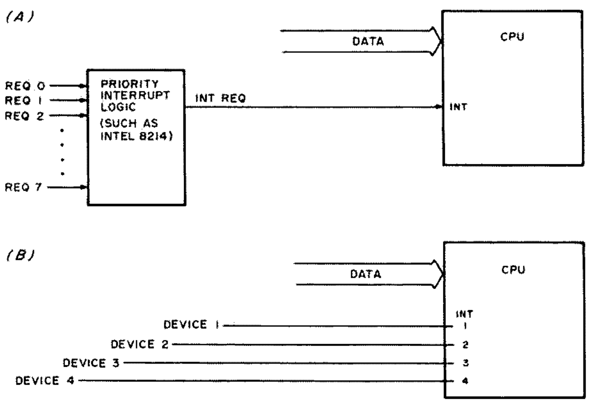

Fig. 2. Multi-level interrupts.

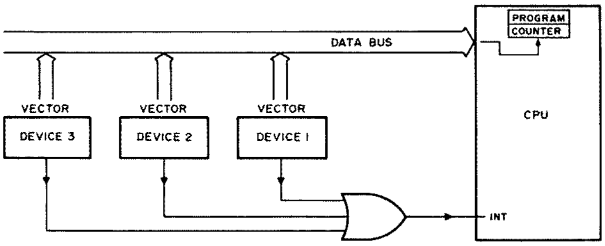

Fig. 3. Vectored interrupts.

Here the processor responds to an interrupt on one line (see Fig. 1). For more than one, the devices are tied to an OR gate and the individual devices must be scanned by the processor to find out which one generated the interrupt (also referred to as "polling"). Because of this, single line interrupts are slow.

Multi-level Interrupts: Here the interrupts could occur on one or several lines going into a priority determination chip or logic (see Fig. 2a). If the number of devices generating interrupts is greater than the number of lines, then some lines must be used as in single line interrupts. The M6800 has two multi-level interrupts within the chip, such as in Fig. 2b.

Vectored Interrupts: In this case, only one line is used, but the interrupting device generates an instruction onto the data bus which causes the CPU to jump ("vector") to a predetermined subroutine. The device priority must be resolved in hardware external to the CPU (the 8080A has a limited form of vectored interrupts). Fig. 3 is a block diagram of a vectored interrupt configuration.

On return from an interrupt, the CPU must be returned to the state it was in before the interrupt occurred. This is often done by a specific instruction, Return from Interrupt (RTI, hex 3B on the M6800). This brings the contents of the registers (especially the Program Counter) back from the stack, so that return to the main program can be accomplished.

With a microprocessor, control lines other than the interrupt lines may be used as specific purpose interrupts, and in most systems they are. The control bus lines, HOLD and WAIT (or their equivalents), are normally used for slowing down or synchronizing the CPU to slow memories. They can also be used as Halts for DMA (Direct Memory Addressing) applications.

The RESET line is a major interrupt line which returns the processor to some initial state to halt the execution of a program. This line could be set by hardware devices any time a major catastrophe occurs (such as a tape drive failure).

Such control lines are normally used to provide versatility for the microprocessor in different machine implementations of the chip and to allow it to be used with a wide variety of devices, e.g., in parallel processing, where several processors are using the same memory (Fig. 4) and switch each other off or on along the HOLD/WAIT lines. Although these lines were designed for interface with slow memories, they are particularly well suited to allow parallel processing and other DMA applications.

An example of the use of DMA would be for slow to fast scan conversions using a microprocessor. The SSTV analog could be digitized (analog to digital conversion) and stored, and the wideband ATV scanned off the same memories by DMA for display on a normal TV set. Think of the graphics facilities this would allow for both SSTV and ATV!

Similar examples of the use of interrupts can be considered by multi-user computers. An example would be to put the microprocessor up near the local repeater and have it accessible to amateurs with RTTY gear. In this case, the use of interrupts would be essential (for timing users, I/O transmission control, etc.).

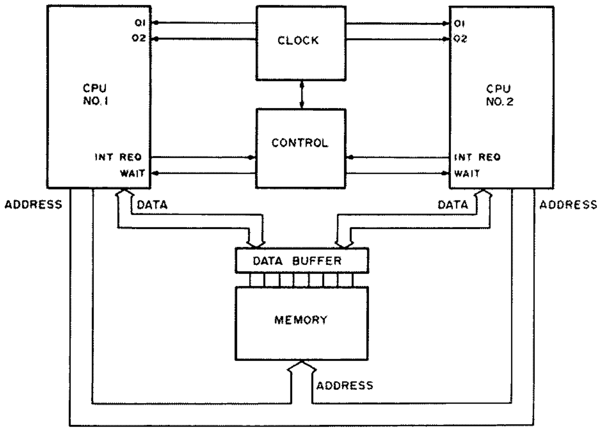

Fig. 4. Parallel processing.

Closer to home, interrupts allow the user to have input and output to several devices occurring simultaneously (or almost) and not wasting time while doing this. As in most computers, the actual processing time is very short in comparison to the input/output time; this means the more time taken for input/output during the processing, the less efficient your programming will be (which may not be a major consideration with home systems today, but will be in the years to come). ■

CW for the 6800

- - it works!

L. C. Wells WA4FMZ
Route #2
Calvert City KY 42029

What? A Morse code reader? And it hasn't been four months since Wayne Green frothed all over his *73* editorial page because another computer mag, in covering computerized Morse code, suggested that 1000 wpm Morse QSOs were possible, and apparently not unlawful. At the moment, anyway.

OK, so I agree with Wayne, at least partially. For one thing, I would probably pay an admission fee just to watch two hams wax extemporaneous at 1000 per. For another, if high speed data transmission is needed, Morse and on-off CW is definitely not the best modulation scheme.

That brings us to this particular Morse reader. It is not designed for high speed, but instead for 5-20 wpm. Its main purpose is to take a subject that a ham has some familiarity with (Morse), and demonstrate what happens as it is processed, decoded, and displayed by that enigmatic box (an SWTP 6800 computer) said ham got for Christmas. If, in the process,

Fig. 2. Decoding table.

said ham discovers that machine language programming agrees with him, and he then goes on to improve and modify this program until it is really good, I shall be happy.

My system consists of an SWTP 6800 with 8K of memory (I plan on a minimum of 16K), CT1024 TVT interface, a surplus full ASCII encoded keyboard which has a lower case lockout key, an AC-30 cassette interface, a 12" Zenith black and white TV converted to a monitor, and one extra general purpose parallel interface board, which is plugged into location 8000.

This is the first programming I have ever tried, so go easy on the criticism; you are definitely not shooting at big game.

I will attempt to answer any questions that my limited technical expertise will allow, and welcome anyone to drop in for a gab session if you happen by my QTH.

The Program

This program will run in as little as 2K of memory, but you do need the extra parallel interface card. Wire the input plug so that I-1 through I-7 are grounded and your hand key (or any make-break keyer) connects between I-0 and gnd.

With the key open, the input line (I-0) floats high like any TTL input. This means the program expects a logic 0 as evidence of activity.

The program does a pretty good job of reading my hand key (very sloppy) or my home brew "accu-keyer"[1] which is reed relay output. It will compensate for speed changes from less than 5 wpm to more than 20 wpm. But, here resides one bug for you to work on. It will not swallow that much of a speed change in one gulp. It must have a couple of letters input at mid-range to bring AV DOT (average dot) closer to agreement with what is actually coming in.

How does it distinguish between a dot or dash? The decoder is based almost entirely on dot length. Why? Did you ever hear an ancient brasspounder on a vibro-plex? A "V" usually comes out sounding like a spooked deer crossing a narrow meadow: three staccato dits and a dah that floats for an impossible time. So, if a single dah lasts for half a day, the decoder will simply call it a "T" and make an adjustment to COUNTER, assuming that the next dit will be of proportionate length.

If the incoming mark is any number less than twice the AV DOT, it is called a dot, added to AV DOT, divided by two, and inserted back in AV DOT as a new average. This is the way it makes speed adjustments. Immediately following a mark, it must decide if the ensuing silence is an element space, a character space, or a word space. We do this by cycling through TIMER, incrementing COUNTER each time, comparing COUNTER to AV DOT each time, and checking for more input each time. If new input occurs before two AV DOTs, it is called an element space, and goes back to process the new input for insertion in TEMP CHAR STORAGE with the last insertion.

If COUNTER gets as high as two AV DOTs, it is a character space, and falls through to the output subroutine, prints the character, then reenters the space routine to determine if a word space is necessary. If it again reaches two AV DOTs without interruption, it again falls through to the print command, but this time a reinitialized TEMP CHAR STORAGE contains only a binary 0000 0001, which, when translated to an LDA-A direct from location hex 0001, loads A with hex 20 (stored there). Hex 20 is an ASCII space, and that's what is printed. At this point, having been through the space decode more than once without interruption, the program jumps back to the beginning, and waits for more input.

Now, how is decoding and storing accomplished? There have been several different methods published. Most involve dual input registers, complementing, adding, and so on. Being somewhat simple to start with, I prefer a simple method. And, if you can call a dit a logic 1, and a dah a logic 0, what could be simpler?

Only one slight hitch: How do you distinguish between an S, M, T, and zero? These would all give an

```

identically empty register. Or worse, how about N and E? Both would give a binary 0000 0001. There would be other similar mix-ups, and changing to calling a dit 0, and a dah 1, is the same situation viewed from the backside. OK, it looks like we need a "place marker." Bingo! That's it. All we have to do is pick a place for temporary storage (we'll use memory location hex 0119), and initialize the data there to binary 0000 0001. Now, when we have a dah to store, we instruct hex location 0119 to "arithmetic shift left" (ASL). This moves everything left one bit, and puts a zero in the least significant bit (0000 0010). When we have a dit to store, it's just a bit more complicated: We shift location 0119 left (ASL 0119); then we store a 1 in the A accumulator. We then add H0119 to the A accumulator and then store the A accumulator in location 0119. In this case, with a single dit and nothing else entered, 0119 would contain 0000 0011. After keying in a properly spaced B, the data in 0119 would be 0001 0111 (see Fig. 1).

Now that we have numbers we can work with, how do we get them on the screen?

With the SWTP 6800, you can use the existing MIKBUG output routine located at hex E1D1. The literature says that to use this routine, the ASCII equivalent of the character to be printed must be in the A accumulator when the routine is entered. All we need do is convert our binary gibberish to ASCII and store it in the A accumulator, then execute a BD E1D1. The ASCII conversion works like this: We need another temporary storage register to put a completed binary character in. We'll use hex 0188. Now, remember that B (0001 0111 in binary)? Since the computer uses hexadecimal notation, let's see what it is in hex:

$$\underbrace{\underline{0001}}_{1}\ \underbrace{\underline{0111}}_{7} = \text{B in binary} \qquad = \text{hex}$$

We tell the computer to load the information found in hex 0119 into the B accumulator. Then we store the B accumulator contents in hex 0188. At this point, we have a hex 17 in location hex 0188 (still dah di-di-dit). Next, we use base page addressing and say: (refer to the program listing, 0187 & 0188) 96 17. This is an instruction which says load the A accumulator with the information to be found in hex 0017. In this mode of addressing, we can specify hex locations 0000 through 00FF. You guessed it, that's where the decoding table is stored (see Fig. 2). At location 0017, the stored information is hex 42, which is an ASCII B.

At hex location 0001, we have stored hex 20, which is ASCII SPACE, so when the program prints a character, then makes two more TIMER runs through space decode without interruption, it prints the information pointed to by location 0119 (which is 01). Then it goes back to wait for more input.

You will note that blanks occur in the decoding table. These are unassigned in the Morse code. Morse was evidently not assembled from a logical base. I would not recommend assigning and using these blanks over the air. The FCC might take a dim view of that.

However, I do urge you to try to follow the program through a cycle (Fig. 3 is a full listing of the program). Armed with that much familiarity, I'll bet you can make changes that will improve it.

Conclusion

After you load the program, set location A048 to 01, location A049 to 1A, then G. To play with the decoding speed, go back to MIKBUG and change the values located at 0000, 0106, 0107, 01A4, 01AC, and 0135. The numbers located there now are not a result of calculations; they were just selected as something that seems to work.

As a suggestion, perhaps two dit lengths is a bit long for an element space, as Morse is actually sent. How about one and a half, and keep two for a character space?

I have tried the NE567 tone decoders for input from my transceiver and haven't had much luck. The 567 takes a few input cycles to lock on, and if the copy is not crisp, or there is QRM, it will often not drop out at all.

Good luck, and may you become more proficient with machine language programming by trying to understand this. ■

The Super Clock

-- what'll they think of next?

Geoffry W. Kufchak WA1UFE
15 Fourth Ave.
Westover AFB MA 01022

Here is a really unique digital clock. Using the Cal-Tex CT7001 MOS/LSI integrated circuit gives you a 12 or 24 hour clock, four year calendar, 24 hour alarm, 9 hour 59 minute timer, 50/60 Hz operation, failsafe battery operation, and will drive either common cathode or common anode seven segment LEDs. The basic circuit is built on a PC board only 3.3" by 5" and will fit in Radio Shack's wood grain utility cabinet. By using a larger enclosure, a back-up battery pack may be added, along with a relay to operate external loads with the timer. Construction cost should be around forty dollars with careful shopping.

The schematic shown in Fig. 1 is adapted from both the Cal-Tex and Radio Shack data sheets, plus my own ideas from past (unsuccessful) experience. The alarm circuit shown, Q14, 15, and 16, is quite annoying in the early hours of the morning. (Anyone want to beat my record of 5 seconds hitting the snooze from across the room?) I'm using an earphone element from an old telephone for the speaker, and it's loud. The display drive circuit can be programmed with jumpers for either type of LED. Fig. 2 is the board layout for multiplexed common anode, and Fig. 3 is for common cathode.

The power supply is simple and straightforward. However, use a heavy duty

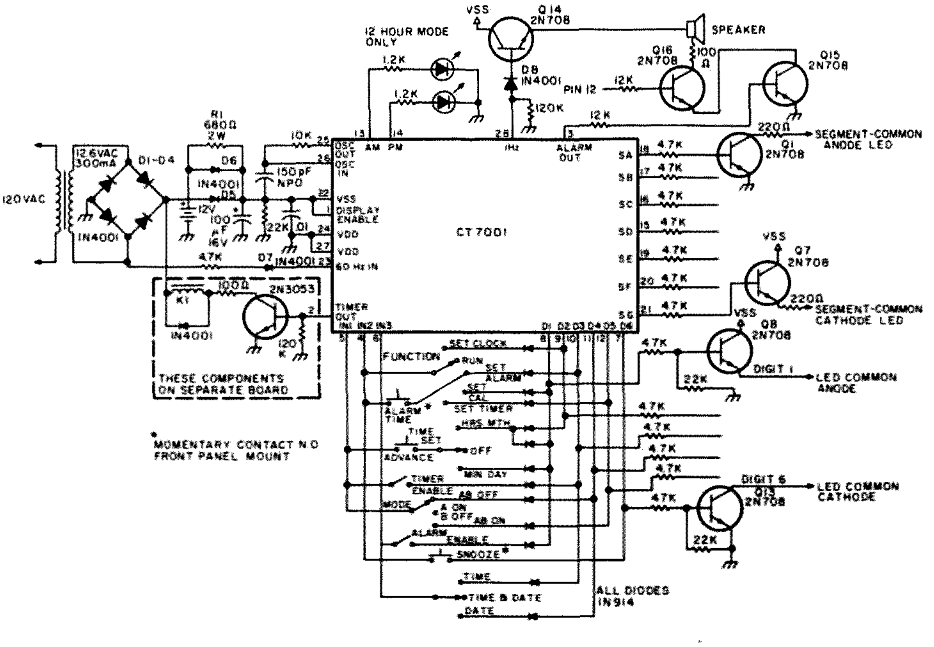

Fig. 1. Select appropriate switching for LED display being used. See Fig. 4.

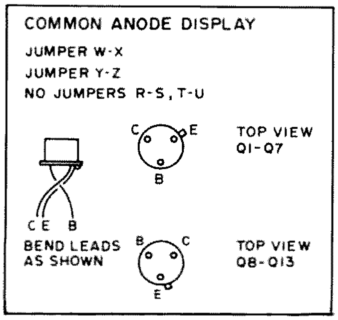
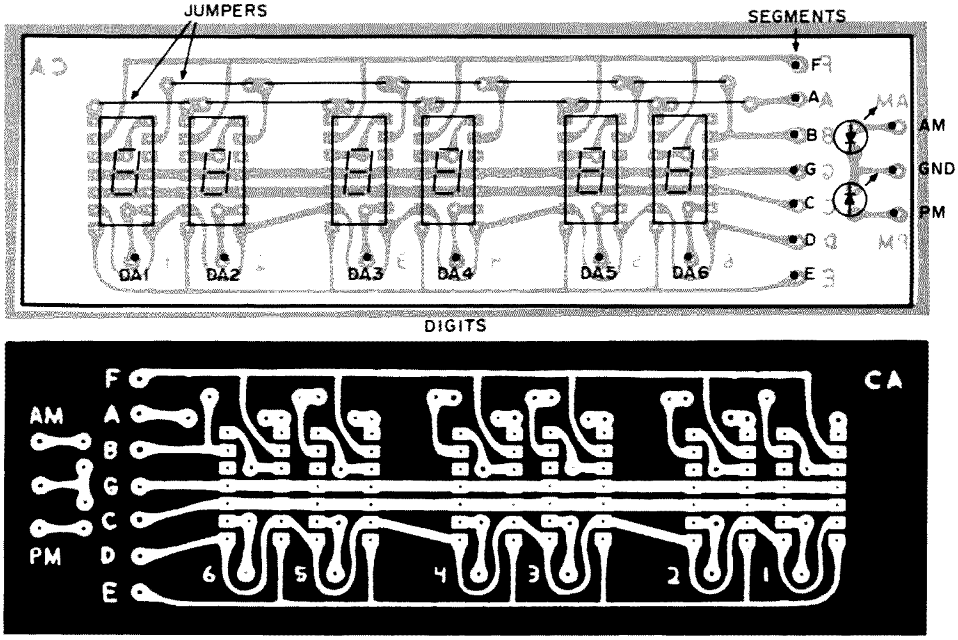
Fig. 2. PC board and parts layout for common anode LED display. Board is multiplexed for Monsanto LEDs: MAN 1, 1A, MAN 5, 7, 8, MAN 51, 52, 71, 72, 81, 82. Cut pin 6 on LED (decimal point) as it is not used. Board is 1.5" x 5".





nicad battery pack, as the displays are wired to be on all the time. Ac is sampled from one side of the secondary of the transformer through a resistor and diode to drive the chip timers and counters. The power supply also supplies current for the timer relay. Use a low current 12 volt relay with contacts rated at at least 3 Amps for driving external loads.

The am and pm indicators will only operate in the 12 hour mode. They may be omitted if you wire for a 24 hour clock.

Fig. 4 is the parts layout for the main board. Please note that an insulated washer must be used at the mounting hole next to Q13 if you use common anode displays. It is not needed for common cathode.

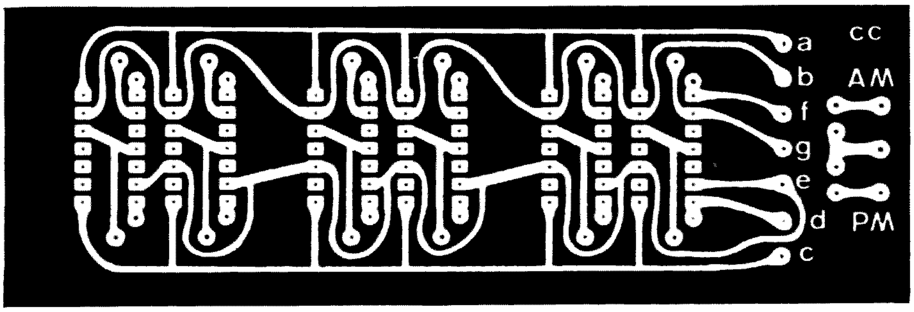
Fig. 5 is a full size negative layout for the main board. Single-sided G-10 is best, but bakelite may be used.

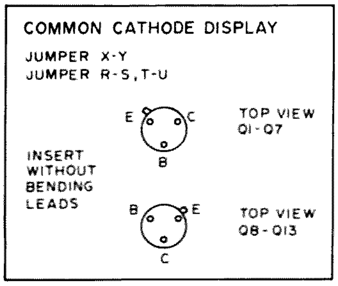
Be very careful with the IC as it can be damaged by static discharges. Once in the circuit it is relatively safe, but can still be destroyed by excessive charges (I found out the hard way).

Fig. 6 is the front and back panel layout for the clock and should be followed if the same cabinet is used; otherwise things just don't fit. The only one that's not critical is the size of the front panel cutout for the display. It may be slightly smaller or larger.

Setting the Clock

First, before installing the IC, check for approximately 15 volts at pins 1 and 22. If you don't get 15 volts, look for a bad diode in the power supply. Disconnect the line cord and carefully plug the IC in the socket. Set the switches on the back as follows: Function-Run, Time Set-Off, Timer Enable-Off,





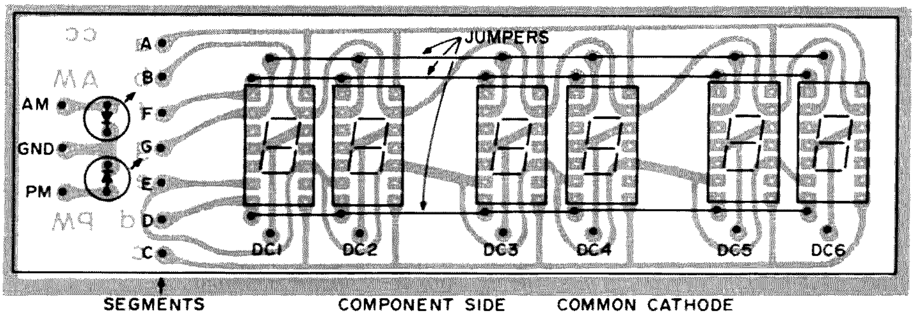


Fig. 3. PC board and parts layout for common cathode LED display. Board is multiplexed for Monsanto LEDs: MAN 54, 74, and 84. Board is 1.5" x 5".

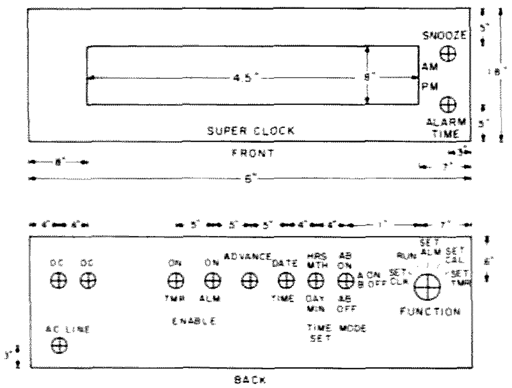
Fig. 6. Front and back panel layout. Snooze and alarm time switches may be mounted on either side of display. Display cutout may be larger or smaller, but should be 4.5" long.



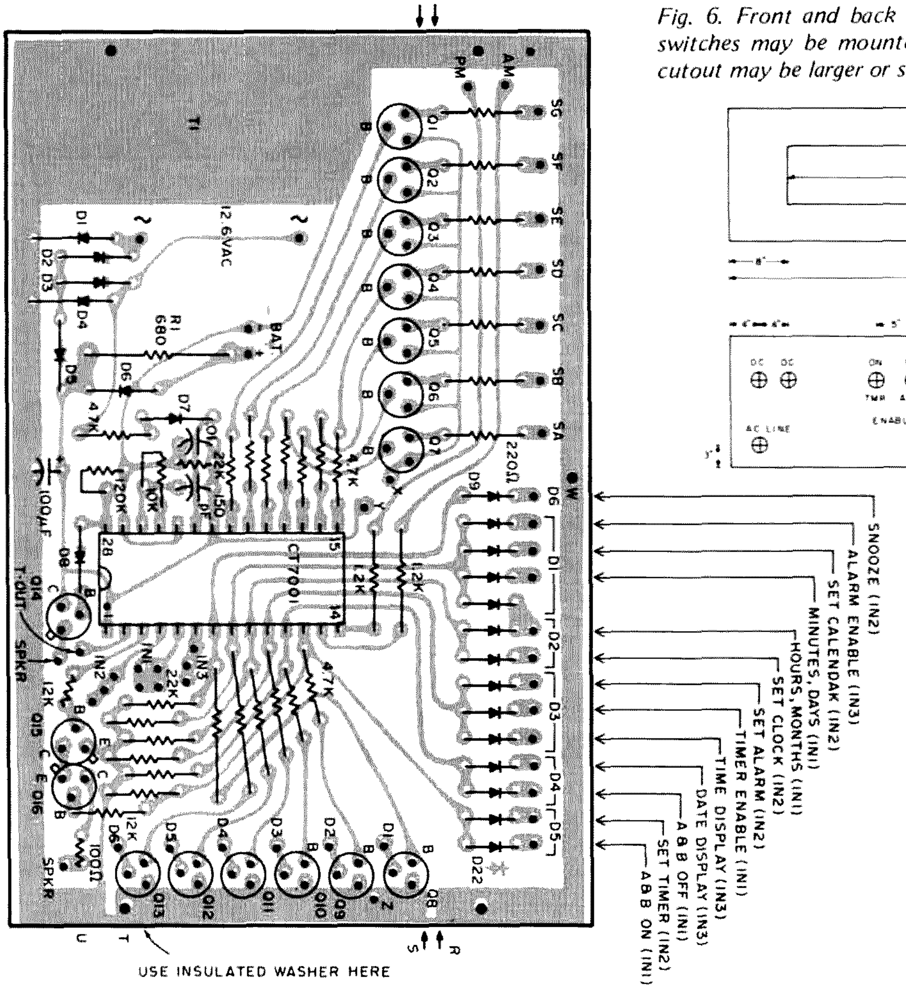


Fig. 4. Main PC board and parts layout. All resistors ¼ W, 10% except R1 — 680Ω 2W. D1-D8 are 50 volt, 1 Amp 1N4001 or similar. D9-D22 are 1N914. Displays are mounted vertically at points marked by arrows, secured to main board with plastic glue, such as Duco cement.

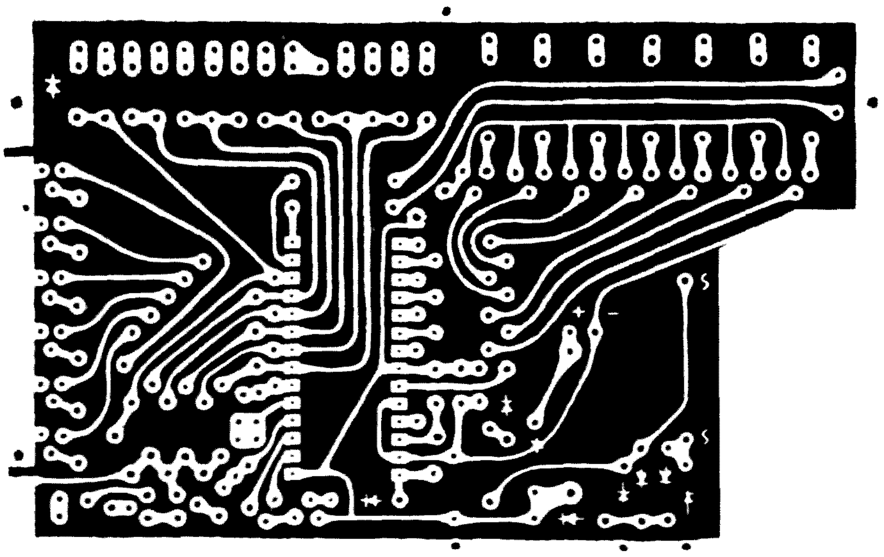

Fig. 5. Full size negative of the main board. When mounting T1 to the board, be sure the base of Q1 does not short.

Alarm Enable-Off, Time/Date-Center position. Plug the line cord in. The display should show all 8s. Set the Function to Clock Set and Time Set to Minutes/Days. Momentarily depress the Advance push-button. The display should change to all 0s. Don't worry if one or more digits are blank. Depress the Advance switch again and the minutes should start counting. Switch to Hours/Months and repeat to set hours. When the time you have set corresponds with the actual time, turn the Function to Run and the clock should start counting. Pay attention to the am and pm indicators when setting the time, as the calendar changes days at midnight. Set the Alarm, Calendar and Timer in the same manner. The Alarm may sound as you rotate the Function switch, but will stop as the times are set.

The Alarm Time push-button is a normally open switch that is wired in parallel with the Function switch so that you can check the time that the Alarm is set for without fumbling around the back. The Snooze switch is the same, and both are front panel mounted for convenience. The Time/Date switch will force the IC to display one or the other. In the center position the time will be displayed for 8

seconds and the date for 2 seconds. The Mode switch controls how the Timer will function. In the A Off, B Off position, pin 3 will be high for the preset time when Timer Enable is closed.

A On, B Off, pin 3 will be high for the preset time and at the Alarm time. A On, B On, pin 3 will be high for the Alarm time. The Timer will only function when Timer Enable is closed. Opening the switch stops the Timer counting, and disables the output.

This IC also has a back-up oscillator to keep time when operating from a battery. If you really want to get it accurate, substitute a 25k pot for the 10k resistor and adjust it as close as you can. Then wire in a fixed precision resistor of the same value.

Parts List — "Super Clock"

1	CT7001 IC	1	5 position non-shorting rotary
16	2N708 NPN	3	SPDT Center off sub-miniature
1	100 Ohm ¼ W	1	SPST sub-miniature
1	680 Ohm 2 W	1	DPDT sub-miniature
2	1.2k ¼ W	3	SP N.O. momentary contact
14	4.7k ¼ W	1	Ac line cord
1	10k ¼ W	1	Cabinet — Radio Shack #270-260
2	12k ¼ W	1	28 pin DIP socket
7	22k ¼ W	6	14 pin DIP sockets
8	1N4001	1	Main PC board
13	1N914	1	Display PC board
2	LED — Discrete		Hardware, wire, plastic window
6	LED Seven segment displays		
1	12.6 V ac 300 mA Transformer		
1	150 pF NPO		
1	.01 uF Disc		
1	100 uF 16 V Electrolytic		

Most of these parts are available at Radio Shack. If you use the above cabinet, get the sub-mini switches, or they won't fit. The seven segment LEDs are from Poly-Paks (common anode).

General Information

Once the clock is working properly and the back-up oscillator is fairly accurate, you may get the idea to use the clock in your car. That is also the reason for two dc inputs on the back: one plugging in a battery to carry it out, and one for operating off the car's electrical system. One word of warning: In some states it is illegal to use red indicators for anything except an emergency condition, so use a different color for the display if you ever plan to use the clock mobile. (All you people with digital tachometers, take note.)

If a larger case is used, the timer relay circuit may be added. With it, you can do a number of different things, such as turn a lamp on and off, turn the rig on at sched time, etc., as long as the relay contacts can handle the load.

If you use a DPDT switch for Alarm Enable, an LED can be wired to indicate when the Alarm is active. This could save you from jumping through the ceiling on Saturday morning.

The only time you'll have to manually set the calendar is Feb. 29th. February is programmed into the IC for 28 days. Oh, well, setting a clock once every four years isn't hard. ■

Add Class to Your Mobile

- - a handset for the rig

Henry Ruh WB9WWM
Box 1347
Bloomington IN 47401

With the popularity of autopatch and other accessories being added to the repeaters, it is little wonder that the touchtone pad is in such demand. While mobile operation is greatly enhanced by a pad in a box on the dash, it is a lot nicer and more convenient to add a complete handset with speaker, mike and touchtone in one handful.

The Trimline™ phone and other similiar designs seem to have been made with mobile operation in mind. With a few modifications they will work with any of the popular transceivers available.

The phone handset has all the goodies necessary for conversion, the base can be discarded along with the cord. You will need a microphone cord with two wires, mike lead and shield. The rigs with electronic switching may need another wire.

To disassemble the handset, pry out the name just above the dial with a screwdriver; this exposes the light and two screws. Remove the light and discard, and remove the two screws and save. Slip the back cover out and down to remove it from the main portion of the handset.

Looking at the cord end with the dial facing down you will observe five prongs. You will also notice where they are attached to the printed circuit. Number them one through five, left to right. Solder the shield from the mike cable to #3, which will be ground (-). Solder a small jumper from #5 to #3 for the dial light return. Solder a 47 Ohm 1/8 Watt resistor from #2 to #4 for lamp power. Solder the mike hot lead to #2.

Now remove the two screws holding the PC board to the earphone element. Carefully pry up the PC foil away from the element. Use the same screws and run a twisted pair of wires from the earpiece terminals down the right side of the handset into the vicinity of the incoming mike cable. Place a layer of black tape over the screws and wires. Now remove the earpiece cover by removing the two screws which hold it in place. With this removed, decide where you will want your push to talk button, and install it appropriately, running the wires down the left side of the handset. Again use a twisted pair of wires.

At the bottom of the handset, join one of the earpiece wires with the "ground" lead from the PTT switch and solder them to #3. The other earpiece wire will go to the black mike cable lead, and the other PTT lead will go to the red mike cable lead. Your handset is now almost finished.

Pull out the earpiece unit carefully and you will notice that it also is the holder for the dial lamp. Install two LEDs of your color choice, one to each side of the lamp clamp. The reason to replace the lamp with LEDs and a series resistor is so you can see the dial in the dark and not have the "short" across your mike lead which the lamp would be if left in. The handset power will come in the hot mike lead.

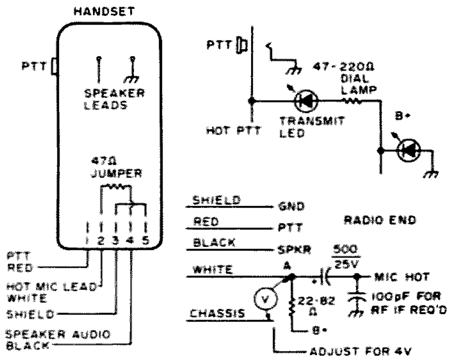
Now observe your transceiver. Either replace the mike connector with one with enough pins for all necessary connections, or throw it away and push your new cable through the hole. It is often more convenient to discard the old mike connector and install a terminal strip nearby, firmly attached to a ground, to hold the end of the new cable. Now it is assumed that your circuit boards have a common ground (not like the Drake ML-2), and one side of your speaker goes to ground.

The shield goes to ground. The hot mike wire goes to its normal place in series with a 500 uF 25 V electrolytic; use short leads. The PTT wire goes to its normal connection, and the hot lead of the speaker goes to the remaining mike cable. Now, find a source of voltage which is greater than 6 volts positive in transmit. Insert a small pot in series with the voltage source and the junction of the capacitor and the new hot mike lead. Adjust the voltage at the junction until you have 4-6 volts. Replace the pot with the closest fixed value *over* the value of the pot reading. This will typically be 22-68 Ohms. A ¼ Watt resistor is sufficient.

Using a Clegg FM-27B, a 56 Ohm resistor was used. No additional adjustment of the deviation was necessary.

The handsets with the integrated circuit produce the best audio and tones when operated from 4-6 volts. Voltage levels above and below this result in low or no audio and distorted, low or no tones from the pad.

For real class, you could use green LEDs for normal dial lights and red LEDs from the PTT to show transmit! Again place a series resistor in the LED lead and run it from the hot side of the PTT switch and the hot side of the



other LEDs, but in reverse so grounding the PTT lead turns on the LEDs. Now that's class.

Also, if you have a Clegg FM-27B, you can improve the receive audio intelligibility and get rid of the annoying speaker rattle by replacing the .1 uF capacitor with a .01 uF capacitor (C-62) and thus roll off the low frequencies.

Now button up the handset, clamping the mike cord so it won't fall out, and put the case back on the radio.

In case you are wondering what to do with the old mike connector: If you have a Clegg, use it to replace the power connector on back for a vibrationless tight connector that won't fall off when you go over the razorback roads. While you're at it, put a couple of miniature (imported) 470 uF electrolytic capacitors across the connector inside the radio. It seems to help if you are having alternator whine on your audio and also smooths out voltage fluctuations.

Happy motoring and QSOing with your new telephone handset. ■

The Final Feeder

-- driving a high power amplifier

Hey Bunky: Building that new contest amplifier and worried about cooking those grids with excessive drive power?

Tried to find neutralizing capacitors lately?

Don't have enough drive for that pair of 4CX5000s in grounded grid?

Well, this article just might be what you need!

Several months ago I was involved in building up a pair of 4CX350As and wanted, out of sheer laziness, to keep the grid circuit as simple as possible. The thought of operating the tubes in grounded grid came first, but Eimac's maximum grid current rating of 2 mA put the kibosh on that idea fast. The only alternative was to feed the grids, but the thought of tuned circuits and neutralization was enough to make me try to find a better way.

Most SSB amplifiers are operated in class AB1 and theoretically don't need any driving power, just voltage. If you look at Fig. 1 you will see a nice 50 Ohm dummy load to soak up the power from the exciter. The power rating depends on the drive; I have 200 Watts available, so I used 20 1k 11 Watt glass resistors in parallel, sandwiched between two pieces of PC board.

The spec sheet on your tube(s) should now be consulted to find out how much peak grid voltage is needed to drive them to full output. Next, calculate the rf voltage across the dummy load, using:

$$\frac{E^2}{R} = W$$

where W = drive power, E = voltage and R=50. If you have 200 Watts available, for example, your available voltage is about 100 volts rms. R1 and R2 form a resistive divider to adjust the drive voltage to the desired level. 4CX250Bs need about 40 volts rms of drive so R1 and R2 should be 1k. This puts 50 volts on the grid which insures enough drive and lets a bit of grid current flow. The actual values of R1 and R2 aren't all that critical. For example, I replaced one of the 1k resistors in the dummy load with three 330 Ohm 2 W carbon jobs in series which gave me a range of adjustment. You could probably use much higher values, say 4700 Ohm jobs in series, and get a little better match to the high impedance input of a tube which should reduce IM products somewhat. The only important factors are the ratio of resistances, and the wattage rating of same. The entire input network loads the grid circuit down so that the chances of the tube taking off are minimal.

When all is put together, watch the grid current. If you get an occasional flicker on voice peaks, you've got it on the nose. If you have too much current indicated, increase R1 some and try again, Good luck. ■

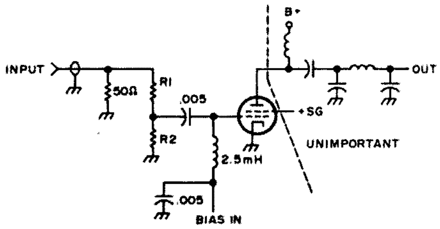

Fig. 1. Power amplifier using resistive grid circuit.

What About Surplus Nicads?

-- how to test and repair them

Alvin E. Ericson W9JTQ
10834 S. Washtenaw Ave.
Chicago IL 60655

If you are the proud owner of a hand-held two meter transceiver, you are aware of the need of a battery pack that is in good condition, particularly when transmitting. Weak or defective cells in the battery will cause the transmitter to lose power rapidly. If your transmitter dies after only 10 or 20 minutes of use after charging, read on. A Motorola HT-220 transmitter will put out 1½ to 2 Watts plus with a fully charged 15 volt battery. When the battery voltage drops to 12 volts, the output of the transmitter will drop to ½ Watt or less. The receiver will continue to operate on 9 or 10 volts with reduced audio output. A good battery should be able to give about one hour of transmitter operation before its voltage drops to 12 volts. In commercial use, the 15 volt 450 mAh Motorola nicad battery is rated at 48 minutes of transmitter operation, 48 minutes of receiving, and 6 hours 24 minutes of standby operation per 8 hour day before recharging. If you purchased a new nicad battery, you should be able to get results similar to these with no problem other than the severe jolt to your pocketbook from the cost of the new battery. They are not inexpensive. You can ease the strain on the pocketbook by going the surplus route and rebuilding used batteries. In addition, you should find it an interesting project to work on.

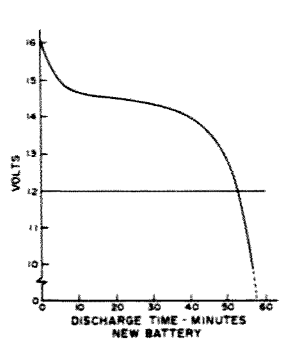

Fig. 1.

To test a nicad battery pack, charge it for 14 to 16 hours at 10% of its mAh rating (i.e., a 450 mAh battery should be charged at a rate of 45 mA, and a 225 mAh thin pack should be charged at 20-25 mA). Rapid charge batteries can also be charged at this slower rate or in a special rapid charger at its recommended time.

After charging, connect a voltmeter across the battery and a load resistor to discharge the battery at the same rate as the transmitter. The load resistor should also match the size of your battery. For a 450 mAh 15 volt Motorola battery, the load resistor should be 32.5 Ohms, and for the 225 mAh Motorola thin pack nicad battery, the proper load resistor is 65 Ohms. Resistors can be connected in series or parallel combinations to get these values and should have a 5 or 10 Watt rating. Take readings of the voltage every minute starting when you begin discharging the battery through the load resistor. After the first 10 minutes, take readings every 5 minutes until the voltage begins rapidly dropping. At this point, take readings every minute again until the voltage drops to about 10 or 11 volts. A nicad battery has reached its fully discharged voltage at about 0.9 volt per cell (i.e., a 12 cell 15 volt battery is fully discharged when it drops to 10.8 volts). To discharge it below this value may damage cells in the battery. Plot a curve on graph paper of the battery voltage vs. discharge time in minutes. New batteries will have discharge curves as shown in Fig. 1. You can see that after the first few minutes of discharge, the battery voltage stays almost constant between 14.7 and 14 volts for quite a period of time. As it nears the end of its discharge, the voltage drops off quite rapidly until it reaches its discharged voltage of 10 to 11 volts. Note that the 12 volt point where the transmitter power has begun to drop drastically is very near the fully discharged voltage as well.

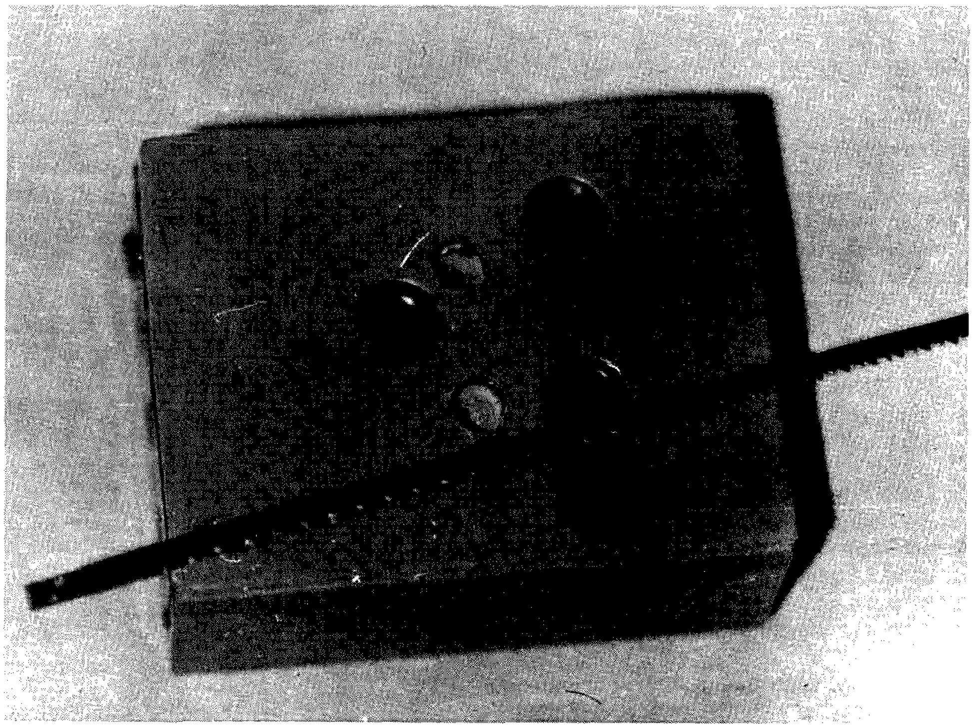

Photo 1. Motorola HT-220 nicad battery with posts drilled out and showing a coping saw blade used to saw around the edges of the top of the case.

What are we likely to find in a surplus nicad battery? Figs. 2 and 3 are typical. The battery in Fig. 2 appeared almost normal for the first 23 minutes of discharge and then dropped abruptly, decreasing rapidly again at 33 minutes. It has two cells that only take a partial charge and become completely discharged at the points of sudden voltage drop. Locating and replacing these cells with good ones will likely result in a battery almost as good as new. You can elect to use it as is if you are satisfied with recharging it after about 20 minutes of transmitter time, since it will deliver almost full power the first 20 minutes. Fig. 3 is more typical of what you will find, however. Here the battery voltage never did come up to full voltage when charged, and it dropped off to below 14 volts rapidly, going below 13 volts after 25 or 30 minutes of use. This lower voltage results in decreased transmitter output almost from the start. The fact that this battery never charged up to 16 volts indicates a shorted cell. Replacing one cell almost brought it up to par, but it still would not last for more than 48 minutes. Locating and replacing the cell that was weak resulted in a battery almost as good as new, as can be seen by the curve just below the new battery reference. You might try Peter A. Stark's (K2OAW) method of "Zapping Dead Nicads to Life" which appeared in January, 1976, *73 Magazine*, to rejuvenate the shorted cell in this last battery. The battery in Fig. 2 does not have shorted cells so would not respond to his suggested treatment.

This method of testing should enable you to identify the type of problem your surplus battery is plagued with: dead cells, weak cells, and cells that accept only a partial charge. Some batteries charge up to normal voltage but lose it overnight or in a few days due to high internal leakage from electrolyte vented from a cell. After opening a battery with this defect, the cells should be washed in running water to dissolve the electrolyte and, after drying, should be charged and load tested to determine the good cells in the battery. I personally have not had much luck rebuilding this type of defect.

The next problem to solve is how to get inside of the plastic case of the battery. I use a thin blade coping saw to just cut through the plastic without sawing into the cells as shown in Photo 1. The two plastic posts near the center of the battery must also be drilled out before the plastic face of the battery can be removed. Most batteries show a dimple where the posts are located. Drill into the center of the dimple with a 1/16" drill. They are hollow and the small drill will feed into the hollow part. Then use a ¼" diameter drill to just drill through the thin plastic. Do not drill too deeply with the large drill because there is danger of drilling into the cells and damaging them. Use the sharp point of a knife to cut through the plastic along the sides where the saw did not cut through completely. It is better to do this than to saw too deeply and damage cells. While this is rather a delicate operation, it can easily be done with a little care and patience. The penalty for sawing into a cell is that you will have to discard it. If you try to saw the battery case apart on the sides along the lines where it was originally cemented together, you will almost surely saw into cells, damaging them.

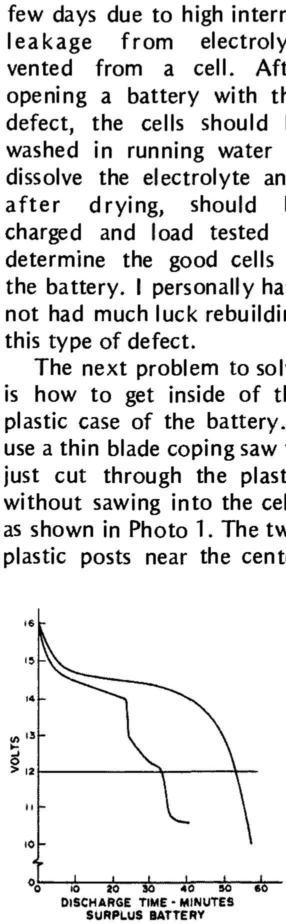

Fig. 2.

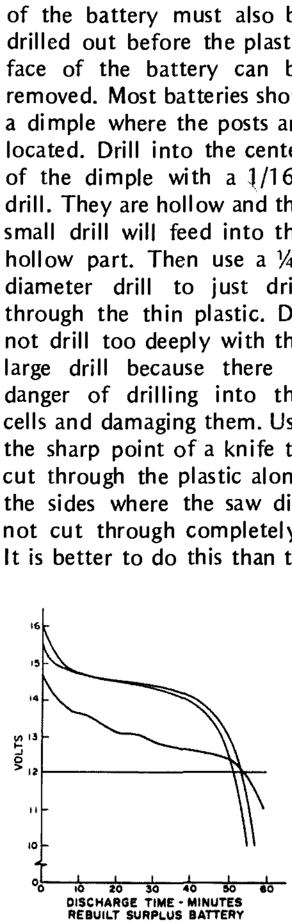

Fig. 3.

Photo 2 shows the inside of the battery after removing the top face. You can pop the cells out of the case by holding the battery upside down over your hand and hitting the palms of your hands together. The cells should come partially out – enough to grasp them with your fingers to pull them out the rest of the way.

Measure the voltage of each individual cell of your discharged battery. To do this you will have to carefully lift the insulating sheet on the terminal connection side of the battery to get at the cells. Any cell that measures less than 0.9 volt on a discharged battery is probably defective.

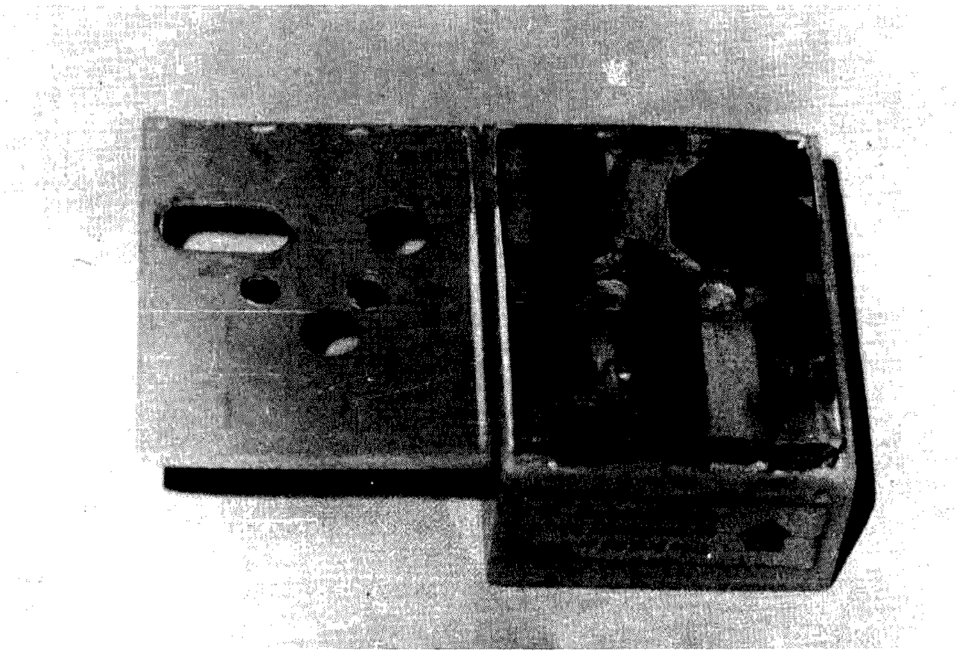

Photo 2. Shows the inside of a Motorola HT-220 nicad battery after separating the top of the case from the rest of the case.

Mark defective cells with a felt tip pen. To make sure that all defective cells have been identified, connect the load resistor across the battery and quickly measure the individual cell voltages. Mark any additional cells that are below 0.9 volt. Using clip leads, connect the battery to your charger and charge it completely. Discharge it with the load resistor and, as it is discharging, measure individual cell voltages to identify which cells discharge first, or are dead.

Repeat this testing procedure on additional used batteries, preferably three batteries. You should have enough good cells to rebuild two of the batteries having the fewest defective cells, and possibly have a few good cells left over for future repairs or for use in some other project.

Remove the defective cells by peeling the connecting straps off the defective cells with a long nose pliers, or better yet, a needlenose pliers. The welds break quite easily. Remove good cells from one of the batteries that you plan to break up, preferably from the same location as the defective cell in the battery you are repairing. If two good cells are adjacent to each other, clip the strap between the two cells, so both can be used. I have used two methods to connect the replacement cells in the battery. I bend the long lead and the shorter clipped lead to form hooks that interlock. When pressed together, they seem to make a satisfactory contact when held by the case after the battery has been assembled. The leads can also be left flat and overlapped slightly and soldered. Put the cells back in the case and give the battery a full charge. Run a discharge test on your rebuilt battery to see how good a job you have done in replacing defective cells with good cells. If you have been successful, you should have a rebuilt battery that meets 80% of the required 60 minutes, or 48 minutes, before it drops to 12 volts. It should also have remained above 14 volts for 35 minutes or more, with a smooth drop-off to 12 volts in 48 to 50 minutes. Starting with three used batteries, you hopefully have been able to rebuild two good batteries and have a few cells left over. In many used batteries you only have to replace one or two defective cells. Use transparent adhesive tape to fasten the cover tightly in place. The pressure from the cover plus the pressure from the battery cover on the hand-held transceiver seem to provide contact between the interlocking straps.

Just a few hints on selecting your surplus nicad batteries: Avoid batteries with distorted, partly melted cases. Most of the cells are usually damaged or in poor condition, probably because the electrolyte has been boiled out of the cells by excessive heat. Select batteries with smooth cases. Many of the pull-outs from commercial service have failed to pass the load test because one or two out of the twelve cells have gone bad. Surplus nicads are available from Spectronics Inc., 1009 Garfield St., Oak Park IL 60304. Surplus Motorola batteries that take a charge and test in the OK zone on a nicad battery tester sell for $10, and those that do not test OK are sold at a bargain 3 for $5. These are the ones I used, so good luck in rebuilding batteries for your transceiver. ■

The History of Ham Radio

- - part II

Eric G. Shalkhauser W9CI
527 Spring Creek Road

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

1917

During the hostilities of World War I, in which the United States was involved from April, 1917, to November, 1918, there were no amateur activities on the air. After the armistice was declared, amateurs still had to wait almost a year before permission was granted to dust off the old equipment, make repairs, catch up on the many changes to be made due to advancements in the art, and become active again.

It is interesting to follow the trend in activities among amateurs during the lull, due to the war. *QST*, the publication of the Amateur Radio Relay League, continued to appear every month until September, 1917. Then followed increased government restrictions, rather severe. The edict: "No radiation, no ground connections, no capacity or inductance to hook-up!" Amateurs were told, "You may read radio books, think radio thoughts, and learn the Morse code, until the call comes to join up." Many amateurs enlisted in the Signal Corps, the Navy, or found employment with the services.

The transmitter of station "2PM", which produced the first transcontinental signals.

1918

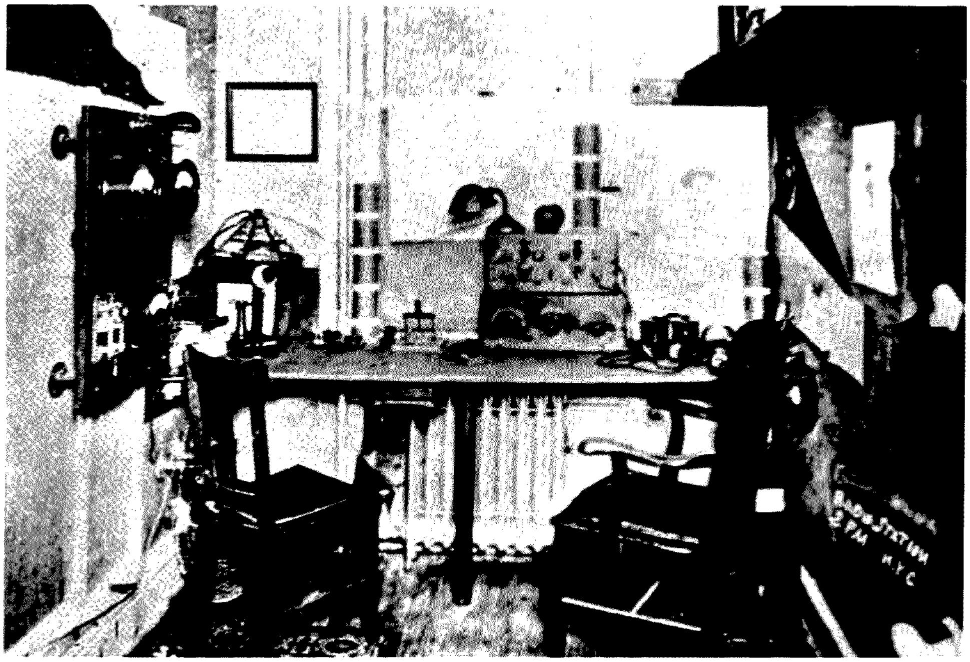
Although the amistice was signed on November 11, 1918, amateurs waited some months before radio publications were again available. The first postwar edition of *QST* appeared in July, 1919, and other periodicals made their appearance, notably *Wireless Age* and *Radio Amateur News*. Restrictions on amateur transmission were removed by the government on October 1, 1919. Here it should be noted that an attempt was made through the introduction of a bill, known as HR 15159, requested by the Secretary of the Navy, to turn over all radio control to the Navy Department. This bill received very strong opposition from the amateur radio fraternity and was defeated.

What were the regulations which now governed the radio amateur? All licenses were cancelled as of April 1, 1917. Rules and regulations had to be followed to go back on the air. Amateurs knew that the Department of Commerce still had complete jurisdiction with William Redfield, Secretary of Commerce, at the time. A publication issued by the Bureau of Navigation, Radio Service, dated August, 1919, entitled "Radio Communication Law of the United States," indicated that no additional radio regulations had been added to those in effect as of the beginning of hostilities. In fact, no changes were made in the radio law during the interim between the introduction of the Act of June 24, 1910, and the ratification of the International Convention of Communications, finalized and signed by Woodrow Wilson, then President of the United States, on July 8, 1913.

1919

Applications for amateur radio operators and station licenses soon had the fraternity by the hundreds back into the swing. The spark coil, the rotary gap, and the old receivers had to be brought up from the basement or down from the attic, unpacked from storage bins, and put back into service. As soon as restrictions were removed, activity started with a vengeance. Radio shops blossomed everywhere. The old wireless bug put everybody to building loose couplers, variometers, honeycomb coils, simple detectors, and a host of new devices.

Along came the newly developed three element vacuum tube. Here was the beginning of the real revolution in reception and transmission of wireless signals. The VT-1 by Western Electric gave the amateurs their first chance to analyze its possibilities. There also were Morehead and Marconi tubes available, but they were very unstable as receiving as well as transmitting units. No two alike would respond equally in a circuit. We were all looking for the advent of larger and more powerful vacuum tubes, and anxious to replace the old spark transmitter. The amateurs knew that it was possible to do away with the noisy spark discharges with their interference problems due to wide bandwidths, and put a new kind of signal into the ether using vacuum tubes.



"2PM" operating position located at 808 West End Avenue in New York City.

At ARRL headquarters in Hartford, Connecticut, where *QST* originated and where our newly appointed secretary and editor, K. B. Warner, took over right after the war, it was decided that the entire body of amateurs be organized into local and regional clubs and associations. The objectives were to foster and promote complete control of all ham activities such as relaying messages, establish relay routes across the country, and keep abreast of all governmental legislation pertaining to amateur radio activities.

K. B. Warner, the new secretary, came from Cairo, Illinois. A very active amateur, he operated under the call 9JT in 1915, using a 1/2 kW fixed gap transmitter.

All amateur radio stations were supposed to be operating on the 200 meter assigned wavelength. Adherence was not too strictly enforced. In fact, some stations were operating well above 200 meters. A few, with special permission, were well into the 375 meter range. So little was known about radio propagation that the erroneous assumption persisted, "the longer the wavelength, the greater the distance waves would travel." August, 1920, *QST* said, "For short wavelengths (below 200 meters) the signal strength is a function of the wavelength, and it may be said that the shorter the wavelength, the weaker the signal." *How strangely the ether waves behaved in those days!*

Everybody was still using interrupted CW, some straight, some quenched, with the only noticeable difference being in the pitch, the whine, and the characteristic interruption of the dots and dashes. Some found satisfaction in a 500 cycle note, if a 500 cycle generator could be found as the prime source of power. Interference created bedlam in many areas, especially before midnight, after which most of the spark coil operators quieted down and went to bed, giving the high-powered boys the ether. The maximum power transformer rating was one kW, usually a Thordarson or Clapp-Estham or equivalent rated at 25,000 volts secondary. The law was specific: "A transmitting wavelength not exceeding 200 meters and a transformer input not exceeding one kilowatt." The ammeter hot wire in the antenna usually was asked to register from 4 to 10 Amperes into an L or T type antenna configuration. It had to be designed and built to a measured length, specifically not over 100 meters, to be within the law. There were plenty of parallel wires, usually at least four, to form a ground network of copper conductors (or buried copper washboilers) for a counterpoise.

The amateurs had a standby pal, "The Old Man," delivering pertinent information to all through articles in *QST*. He kept all in good humor and within the straightjacket of operating procedures. As an example of what could be expected from the OM, here is an excerpt directed to the editor from June, 1919, *QST* under the heading "Rotten Starting":

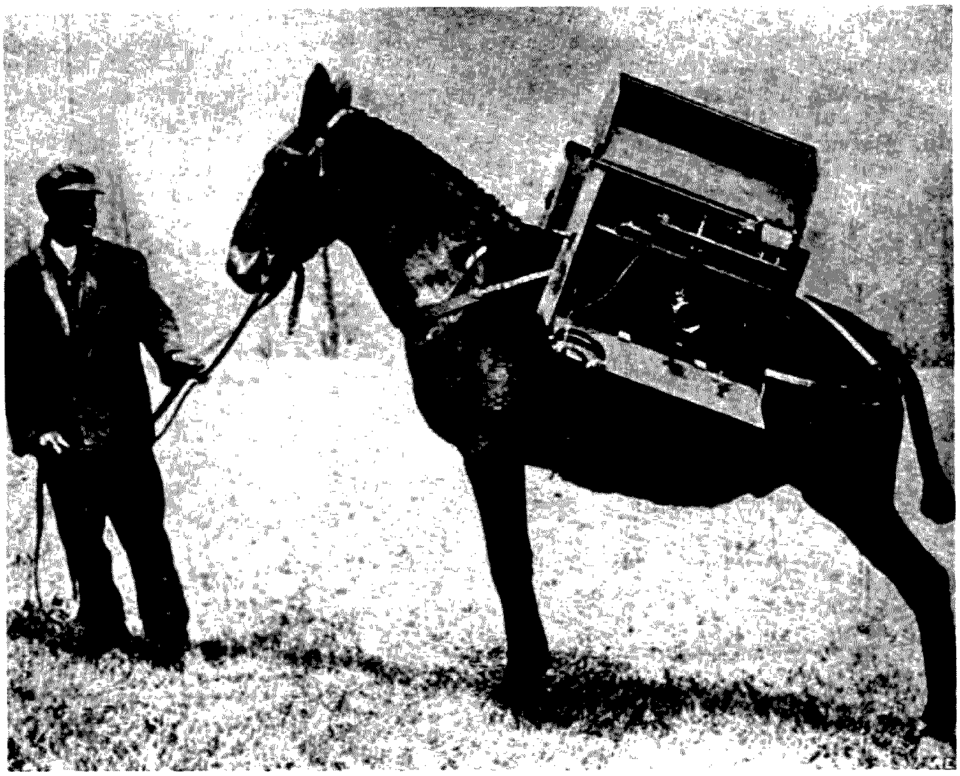
> "I am sending you a specimen of a *Wouff Hong* which came to light out here when we started to get our junk out of cold storage. Keep it in the editorial sanctum where you can lay hands on it quickly in emergency. We will be allowed to transmit soon and then you will need it."

Who does not know the *Wouff Hong*?

What most of the amateurs surmised and expected was just ahead. We read in November, 1919:

> "There will come a day when amateurs will not need to bother their heads about government or commercial stations, but THAT DAY HAS AS YET NOT ARRIVED. The radio millenium has still to come. We mean by this that with our present form of crude apparatus still in vogue, and when we are using quasi makeshifts, we cannot expect that we can tune our transmitters down to within the hundredth fraction of a meter. Usually the amateur wave is so broad that it can be picked up all over the scale. As long as we persist in sending out such waves, we must expect criticism from the big stations with which we interfere."

The junking of the radio spark gap was in the making. To actually let go was an-



"Mule Mobile" was used by the Signal Corps during World War I for carrying the not quite portable transmitting equipment.

other thing. Some of the old-timers in 1920 complained that there was no romance in tube transmission – that it has no individuality or traditional associations like the old spark. There was always a certain stalwart and hearty attraction about the old non-sink rotary, noisy and inefficient as it was. So the *Old Guard* had to finally succumb also to *the little bulbs that had nothing in 'em.*

This is what Dr. Lee DeForest had to say at this time, the man responsible for the development of the three element tube, in November, 1919:

> "The average radio amateur knows enough of the extreme selectivity which the pure undamped wave makes possible, to realize that the problems of interference would largely vanish with the spark gap. Let the amateur urge upon his Congressman or Senator that if the government wishes to further legislate against radio interference, then legislate out of business the damped wave transmitter."

1920

So it became necessary that the amateurs gradually develop the use of the vacuum tube for the various modes of CW transmission, modulating via key and voice, and for better receiving possibilities. With better sensitivity and selectivity built into receivers, our efforts were now directed toward solving the *QSS Bugaboo*! What is QSS? The Q code gives no definition. So – take a look into the May, 1920, issue *QST*, page 25. Well, since you do not have a copy, this "new" abbreviation was added to the list, adopted by ARRL to fill a need. What does it stand for?

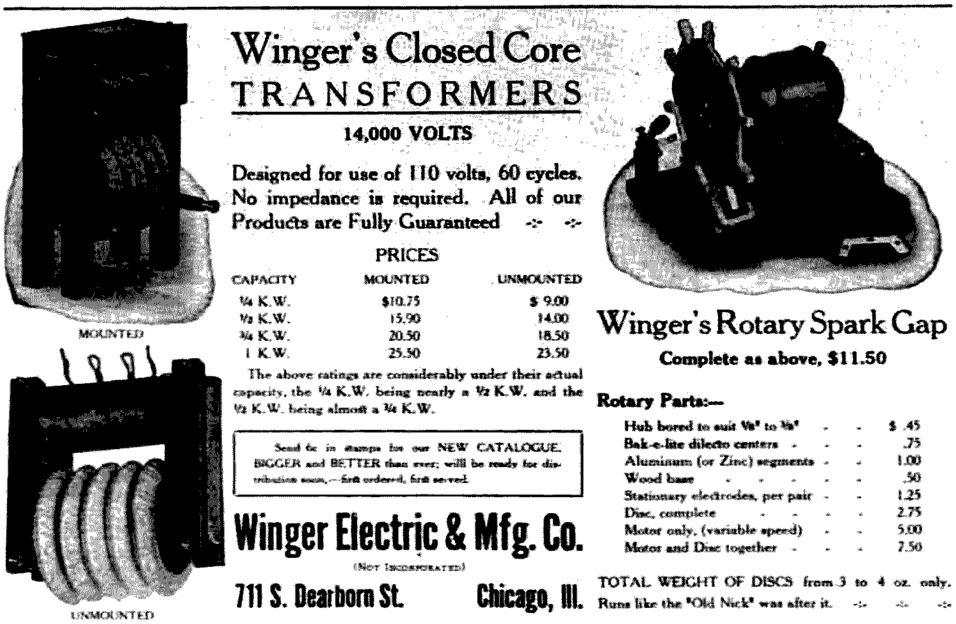
QSS? – Do my signals fade?

QSS – Your signals fade.

Although rarely used, this abbreviation, even in these days, makes sense.

Amateur radio was not out of the woods regarding clear sailing without periodic attempts on the part of the government to curb their activities. The Poindexter Bill, originating as document #165 through a letter from the Secretary of the Navy, was in the hopper. It stood facing the amateurs later on as Poindexter Bill S-4038, and did not bode good news for the amateur.

The time loomed on the radio horizon in 1920 to be thinking about international regulatory legislation to bring radio communication the world over under better control. A meeting of the International Communications



The "latest" in ham equipment just before all amateur activity was banned during World War I.

Convention in Berne, Switzerland, was on the agenda. The radio amateurs had to have prominent representation. Intensive efforts were made to protect the rights and privileges belonging to the amateur. Charles H. Steward, member of the ARRL Board, was appointed legal counselor to speak for the amateur in these matters. In order to cement more firmly the ties that bind, amateurs decided that in numbers and in get-togethers there is strength, and much could be accomplished via this route. The thinking centered on having regional conventions, typical gatherings to meet each other personally, to set out program meetings, and to air mutual problems.

One of the early conventions took place in Chicago, sponsored by the Central Division Managers of ARRL. Held September 2 to 4 at the Edgewater Beach Hotel, there were about four hundred in attendance. There had been similar conventions held in Boston and Philadelphia, but this one in Chicago was to be of wider scope in quantity and quality to bring home to all amateurs what we were up against. The report issued from headquarters: "The convention out-conventioned anything yet pulled off in amateur radio."

9AHO,
Dear friend,

Received ur card of the 15. Am sorry to say I hv never hrd u since that sunday nite. The other hrd YJ give u a msg, or something, dont remember. hv been hrd in Des Moines and Owatanna, in the daytime. I hv a tuner with a slider which I am going to junk an then maybe I can hr more. It wrks ok this way but the slider must be set a certain way or the sigs fade. hv wrked YJ and 9MN. These two r my longest distances. Owatanna cld copy me in the daytime but he cldnt wrk me on account of QRM. nxt time I hr u I will call u.

Ur friend,
John C. Rees.

An early QSL card, sent in 1917.

Not to be outdone, and to top off the year 1920, the Midwest ARRL Division decided that St. Louis would be the next place for a meeting. The time, December 28 to 30, under the sponsorship of the St. Louis Radio Club. Everybody of note in amateur radio circles showed up, from the President Hiram P. Maxin, the Editor K. B. Warner, the Chicago gang, Paul Godley, M. B. West, R. H. G. Mathews, and of course, "The Old Man" himself, who gave a stirring account of the "joyous" and glorious" three days.

To be continued.

Wind Your Own

-- cheap filament power for that linear

A major expense when it comes to building that linear is the price of the filament transformer. Fortunately, one or two of those obsolete tube power transformers can get you over that expensive hurdle with only a little time and a few cents invested.

First weigh your transformer to determine capability. Refer to Fig. 1, which illustrates the relationship between weight and filament power capability. For example, if the power transformer weighs 4 pounds, it should have a filament power capability of 60 Watts.

Next determine if the transformer is adequate for your application. Let's say you have a transformer with a recycled capability of 60 Watts and you desire a new secondary for a 4CX1000A high power ceramic-metal tetrode. As the 4CX1000A has a maximum filament power requirement of 59.4 Watts (6 volts x 9.9 Amps), you could indeed use this transformer for your filament supply. You could also use two thirty or forty Watt transformers in parallel.

Once you have selected your transformer, disassemble the outer case and note the location of your primary winding in respect to the core of the transformer. The primary leads are usually color coded black. Make sure your transformer has a 110 volt, 60 Hz primary, as some surplus transformers have odd primary voltages that operate at other than 60 Hz. Also, some transformers do have their primary near the outer core and, generally, this type of transformer provides little area for your new secondary. Transformers that have the primary wound tightly around the center core provide the most area and versatility for your new secondary.

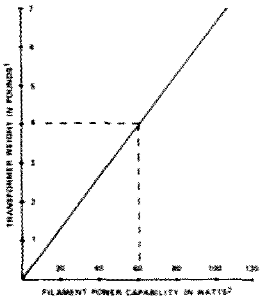

Fig. 1. [1] *Weight excludes mounting fixtures. If case is of heavy steel construction, remove before weighing transformer.* [2] *Data based on an analysis of typical transformers.*

After you have located the primary, cut off and remove with a hacksaw all secondary windings that are wound *around* the primary. Work slowly and take care not to cut or damage your primary winding.

After completion of your cutting, inspect the primary for damage. Next, wrap the primary winding with one layer of plastic tape. Securely attach and insulate the primary leads.

The number of load turns per volt must next be determined. Wind approximately 4 turns of no. 18 insulated wire around the primary as a temporary secondary. Apply the normal primary voltage (110 volts, 60 Hz) to the primary and measure the output voltage of your temporary secondary with an ac voltmeter. The voltmeter reading will determine the turns per volt. For example, if you measure 2 volts, you know it took 4 turns on the secondary to produce this 2

volts; therefore, the turns per volt is 2 turns per 1 volt. Keep in mind this is the no-load turns per volt.

After removing the temporary secondary, wind your permanent secondary. I use two no. 14 wires in parallel for my secondaries, as this is quite easy to wind around the primary. Two no. 14 copper wires will be adequate for secondary current levels up to 10 Amps, 5 Amps per wire. The insulation on the wire should be capable of withstanding at least 10 times your output voltage. Example: If the secondary output is 7 volts, the insulation should provide protection up to at least 70 volts or higher.

Always allow about 50% more wire than your turns per volt indicated, as you will have to increase the number of turns to compensate for the transformer resistance when operated under load.

A filament transformer must have the correct output voltage under load; therefore you must load your secondary and take periodic measurements during its construction.

Let's say for example you require 6 volts at 10 Amps. According to Ohm's Law the load must be .6 Ohms.

$$R = \frac{E}{I} = \frac{6\ \text{volts}}{10\ \text{Amps}} = .6\ \text{Ohms}$$

Therefore you should load the secondary with a .6 Ohm resistor while measuring the output secondary voltage. Ohm's Law requires the power dissipation of the resistor be at least 60 W.

$$P = IE = (10\ \text{Amp})\ (6\ \text{volts}) = 60\ \text{Watts}$$

However, a much smaller wattage resistor may be used if you work rapidly and do not allow the resistor to heat up.

That's it; good luck on that linear. ■

Discriminator Output for the HR-2A

-- check deviation and modulation

A very simple addition can be made to the Regency HR-2A and other FM receivers which will provide output for a frequency shift meter, scope, tape recorder or for whatever other purposes a discriminator output is required. A partial diagram of the HR-2A discriminator is shown in Fig. 1. Refer to the schematic diagram of your receiver to locate the equivalent takeoff point.

At test point TP-A, add a 10k resistor and a .01 capacitor to filter out low frequency variations of the discriminator dc output. The other end of this filter connects to an unused terminal on the speaker terminal strip. Fig. 2 shows the circuit of the filter and output wiring. To use the discriminator for meter operation, connect a VTVM to terminals 3 and 4 of the speaker terminal strip and set the meter to the 5 volt dc range. Turn the receiver to a channel that doesn't have a signal coming through and adjust the meter for center scale reference (2.5 volts). You can now switch the receiver to any station that you may wish to check, and see how far they are off zero by the amount of the meter deflection.

In this particular set, the frequency shift is .30 kHz per division of the meter. To calculate how far off zero a station is, merely count the number of divisions above or below the zero center position that the meter indicates and multiply this by .30 kHz. As the frequency shift per division can vary from set to set, it's a good idea to check your own calibration.

Another useful application for the discriminator output is to check the modulation (deviation) of received signals. To do this, connect an ac scope input across terminals 3 and 4. Set the sweep frequency to a low value and observe the modulation peaks on the scope. Set the vertical gain control so that a normal signal deflects the scope to some convenient height. Now, as other stations come through you can tell whether their modulation is excessive or too low. This same hookup can also be used to set the level of a Touchtone pad. Have the operator of the station that you are checking whistle into his microphone, and observe the height of the scope pattern. Now have him press one of the buttons of his pad and adjust the output level control for the same deviation as produced by whistling. Although this may not be the optimum adjustment, it is a good starting point.

When not using the discriminator for any other purpose, it can be left connected to the AUX input of a cassette recorder. Now anytime that you wish to record an incoming signal, merely start up the recorder and adjust the record level control for proper operation. The volume control and tone controls of the receiver will have no effect on the discriminator, so it can be set to please yourself. There are many other uses for the discriminator output on a receiver, but only a few have been mentioned, just to start the mind working. ■

The Phantom Exposed

-- everything about crosstalk on Ma Bell's lines

By FCC regulations, phone patchers must be careful to avoid high levels when they connect to telephone lines. There seems to be a point where the effects boil over, but a little less makes no trouble at all. Some of us know that it is crosstalk that bothers Ma Bell and the FCC, and this must all come from the conductors in the cable. So why is this effect so abrupt? For that matter, why crosstalk at all? Hasn't Ma Bell heard of twisting wires to eliminate coupling, and of coax?

Yes indeed, she has. In fact, the old girl invented these and a lot else besides. Trouble is, no method *eliminates* crosstalk; at best, it reduces it to a tolerable level. And nowadays, "tolerable" is the best you can afford, the "state of the art."

Fig. 1 shows the classic old farmer's line, the single wire working against ground. It works up to several miles, so long as it is the only circuit on the pole line. Of course, it is a good antenna too, and how many times has it been used as one! It picks up static and power hum on a clear day, and you can hear a storm coming while it is miles off.

Fig. 2 is the classic "full metallic" line. Both conductors are above ground, both literally and electrically. The center tap of the line transformers, or "line coils," may be center tapped with the center tap grounded or not. In any case, there will be lightning arrestors which offer a breakdown path to ground. Even on a clear day, a long insulated line may pick up several hundred volts of static charge. Ask any lineman! The signal is "push-pull" so that the two wires of the pair are always opposite phase.

Static and induction affect both wires in phase, and cancel out in the windings of the terminating transformers. That is, they affect both wires equally if the source of the interfering field is some little distance away, such as a paralleling power line. But string another pair of wires on the same cross-arm, and the coupling between them is both much closer and much less balanced, as is shown in Fig. 3.

Simple Balance Scheme

Fig. 4 shows a simple balancing scheme I have seen used by some radio stations, when they want to run two transmission lines together. The pair numbers are 1-2 and 3-4 and they share a common center point. If you made up two lines with ribbon leads, you would have to split the pairs so that wires 1 and 3 were in one ribbon and 2 and 4 in the other. The spacing would have to be close and critical, so that ribbon lead is not practical. These lines are always open wire ones. But it does work. Notice the bridge symmetry of the capacity couplings.

Transpositions

Untransposed lines are good for a mile or two. After that, you can't tell which line is being talked on — you hear either or both nearly equally well. They are still balanced so far as static and line hum are concerned, but violently unbalanced for the adjacent pair. Only one wire working against ground would be worse.

Fig. 5 is what we do about it. At the middle, you just interchange the wires on one pair, and immediately you're in business! Wire 3 is close to 2 for half its section, and 4 is close for the other half. 3 and 4 are out of phase, so the inductive effect cancels. Of course, 3 and 4 couple to wire 1 also — the coupling is less, but present, and cancels with it in the same way. The net result is, no crosstalk. Swell! Our telephone plant is growing, so let's add another pair, 5-6. Immediately, we're in trouble: If we transpose it, it will crosstalk with 3-4, and if we don't, it will crosstalk with 1-2.

The Transposition Plan

If Fig. 5 worked once, maybe it will again. Let's transpose 5-6 in the middle, so it won't couple to 1-2, and then transpose each half again, to break up the coupling with 3-4, which gives us Fig. 6. Now we're in business — until we add 7-8. If 1-2 has no transpositions, 3-4 has one, and 5-6 has three, it would seem that 7-8 would need seven. And that's exactly right. And by the time you got up to a full forty wire line, the whole scheme would be quite impossible — you'd have to transpose wires in the middle of the span. Oh yes, this has been done, too, but not for this reason.

The Phantom Group

No communication business ever has enough circuits. Ma Bell came up with a good trick generations ago — the phantom circuit, Fig. 8. Just connect an extra pair of line coils to the center taps of the 1-2 and 3-4 coils, and you get a third circuit,

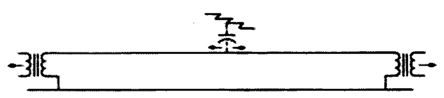

Fig. 1.

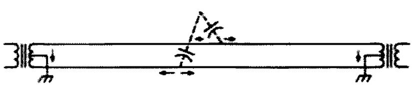

Fig. 2.

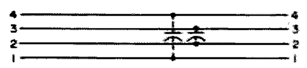

Fig. 3.

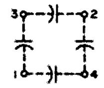

Fig. 4.

practically for free — three circuits on four wires. By means of the center taps, the phantom circuit uses 1-2 (side 1) in parallel as one wire, and 3-4 (side 2) as the other parallel wires. It is called "phantom" because you can't see any wires for the third circuit.

Ghost

The old girl got carried away for a time with the phantom idea. Here was another center tap on the phantom coil — why not go further and make a phantom of the phantom? It actually worked, and the "ghost" was born. Now you could get seven circuits on eight wires. Trouble was, the ghost circuit worked only an alternate Tuesdays — it was always too wet or too warm or too something, and they were the devil to keep balanced. So the ghost was soon kicked out and the standard became a number of phantom groups.

Phantom Group Transpositions

It may have occurred to you that, with two wires of a side circuit used in parallel for one side of the phantom, transpositions in the side would become ineffective so far as other phantoms were concerned. And that is exactly right. Fig. 9 was developed to cope with this effect — you just swapped the pair position bodily with its mate, which transposed the phantom just as a side would be transposed. But the solution worked for more than just the phantom group. By transposing the whole business in this way, the whole transposition plan was greatly simplified. Remember that it began to look as if the highest-numbered pair would turn out to be a continuous spiral, with hundreds or even thousands of transpositions in it? Every time you added a pair, it had to have nearly double the number of transpositions in it. Now you can divide your pole line into phantom groups and just transpose them. This is one case where the solution overshadowed the problem!

So far, we have four main types of transpositions. These are: Type 1 which turns over the low numbered side; Type 2, for the high numbered side; Type 3, which transposes the phantom; and Type 4, which transposes both sides *and* the phantom at the same point (Fig. 10).

Mules

Pole lines are installed by construction gangs, a group of non-sissies under the leadership of a gang foreman, who is no sissy himself. Remember that these men haul poles around and string wires on them over rough country, which takes rough men. The wires themselves are more like hard-drawn copper rods; the smallest is 1/10 inch in diameter and the largest is about 1/6 inch. The linemen delight in getting some engineering type to try cutting the wire with pliers. The men cut the wire snip-snip-snip like cutting toenails, and the indoors type can't even nick it. It teaches him who he is dealing with and saves trouble all around.

Such wire is very heavy and, in most cases, four reels of wire were hitched to a mule, who was as tough as any of the men. He pulled the

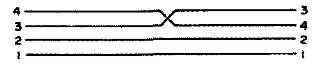

Fig. 5.

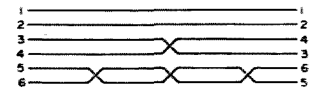

Fig. 6.

wire off the reels while the men kept it from tangling and got it up on the cross-arms and later tied it to the insulators. They had to "cut" the transpositions at certain pole numbers, according to plan, as shown on a big blueprint. Mules are far from stupid, and they soon caught on to what was going on. Entering into the spirit of the thing, the mule would cock his eye at the pole and recognize it as a Type 4 transposition point. Then he would lie down, roll over, and get up, thus cutting his own Type 4 without human help. Many linemen have told me this, with perfectly serious faces, and who in his right mind would doubt the probity of a man who can hike a pole faster than you can climb stairs, with a hundred pounds, more or less, of tools hung on his belt! Not me!

Foremen

In fact, back at the hotel or boarding house, there were frequent arguments about who was smarter, the mule or the foreman. Surprisingly, the foreman had his champions, too. Maybe out of sheer loyalty, maybe just to keep the argument going — what else is there to do in a strange, small town at night?

Carrier

Up to this point, we have ignored Fig. 7, but now the story has caught up to it. When you run out of circuits, the obvious thing is to build another pole line. This calls for another right-of-way and many times this is impractical or impossible. Just after WW I, Carrier Telephony was invented by Major General Squires of the Signal Corps. Or at least one variety of it was. He liked the high frequencies and one wire, while Ma Bell used two and frequencies between 7 kHz and 20 kHz or thereabouts, for her A, B, and the good old C-type carriers. The C lasted for a couple of generations — about as long as open wire lasted — and was an excellent system. On a phantom group that already carried three voice circuits, you could get an additional six with two C systems. This effectively doubled the capacity of the lines, at minimal costs.

Trouble

This unsolved the transposition problem, however. Fig. 7 shows why: The sine wave is an interfering carrier signal. It does not affect the lower side circuit 1-2 because as the phase reverses, it induces alternate plus and minus charges which cancel. But at the same time, it induces a plus charge on 3 and a minus on 4, because the line transposed at the same point the sine wave went through zero, and the charges induced *added in phase* instead of canceling. There was

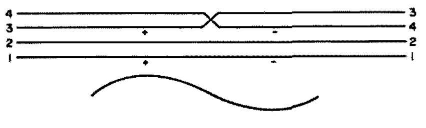

Fig. 7.

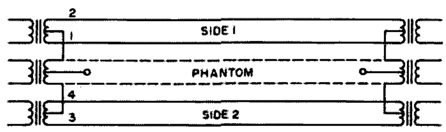

Fig. 8.

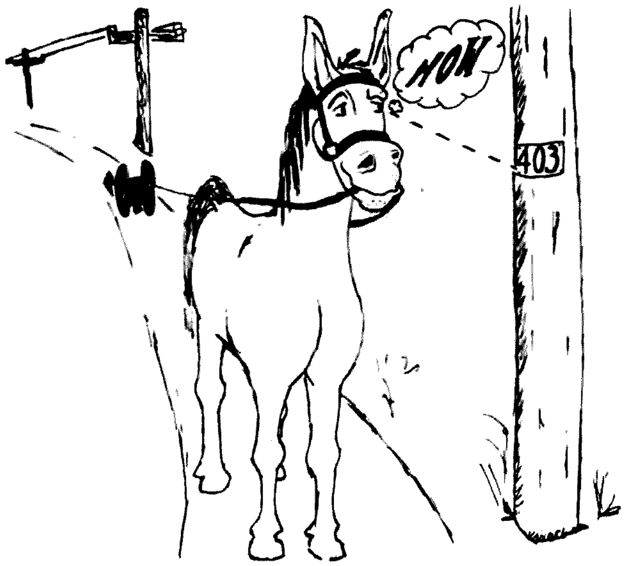

nothing for it but to retranspose the whole blooming shooting-match, which was costly and a lot of trouble, but the only way out. Carrier transpositions are just like the others, but are many times as often. The idea is to get several transpositions along just one of the highest carrier wavelengths. This means every pole or two.

Beacon Mountain

Across the river from Newburgh, New York, lies Beacon Mountain. At the bottom of the mountain, everyone puts his TV antenna on the highest mast he can afford, because it is a fringe area, and the fringe is marginal at that. Halfway up the mountain, however, the antennas are mounted directly on the roof, or even in the side yard, which must be an eye-hazard when mowing the lawn. Up near the top you don't see any antennas at all. Maybe they bury them to take advantage of the ground wave. It wouldn't surprise me any.

But under the crest, where there is still some mountain left, but the ground is nearly level, the TV set owners have to harvest all the obstacle gain they can, because the mountain seems to shadow more at this point. I remember one installation – house backed up to the mountain, long front yard extending, nearly level, away from it. Out near the road, a couple of hundred feet from the house, I saw a grubby old conical antenna mounted on a wooden platform which had sled runners on it. Obviously, the owner had hauled it around the lawn until he picked up a "commercial" signal. He used an ordinary ribbon line, supported on what looked like clothes-poles.

Now suppose his brother-in-law had moved in, complete with TV? He'd get the oscillator from the other TV into his own as sure as sin.

Me, I'd leave the original line alone and make him twist his at the rate of a turn in two feet or so – anything shorter than the shortest half wave would do. Instead of threatening him with mayhem, I'd just mention that the spiraling effect made the signals auger their way into the TV set, making a better picture. No argument would be necessary.

Cable

Open wire illustrates the crosstalk problem and its solution as nothing else could, but cable is the facility today. All you have to do is twist the pairs like old-fashioned lamp cord and you can forget about transpositions, isn't that right? Isn't it?

No. Cable pairs come in phantom groups also, but here they are called "quads." If you lay two twisted wires together, they nestle like spoons and you wind up with a swell case of crosstalk. So you have to use different twists for different wires; you have to twist the pairs around each other, you have to interleave the quads, you have to even swap layers in the cable. A cable is one devil of a complex thing! And always, no matter what, there is a little crosstalk that gets in.

If the average level of the circuits at that point is, say, minus 10 dBm and the crosstalk is minus 50, you can forget it. The conversation will drown it out handily. But if the crosstalk comes from a pair with a minus 7 instead of minus 10 level on it, three dB high, the crosstalk will also be three dB higher and you can hear it – just. In fact, the residual noise you hear is mostly the babble from many circuits. But another three dB and it begins to be serious.

Hello

The English word "hello" can be recognized when no other word in the language can. Telephone men can let a hello go by, but any other crosstalk that can be understood requires that the crosstalking circuit be disabled. This is Telco rules and FCC rules, to protect privacy. I have even cut broadcast lines when I heard understandable crosstalk on them, and got away with it. Ma Bell wasn't happy about it, but it had to be done. So if YOUR line crosstalks into others, it will be cut too, as soon as Telco can find it. You won't be reconnected until you fix the level.

Coax

Why not go to coax and get the improved shielding? Simply because coax is a high frequency line. The shielding works at frequencies where skin effect is important. You have cable with a single outer braid where flexibility is important and crosstalk permits. For more severe conditions, you have double braid cable. Next is solid tubing, and if that doesn't work, move it somewhere else.

Shielded Pair

You don't see much of it, but Telco uses a lot of 135 Ohm shielded pair, which is operated balanced just like cable pairs are. It is especially effective at lower frequencies. The shield is grounded at one end, usually, but maybe at both and sometimes in between. You have to insulate the shield, then ground it at a point where ground potentials are least, since ground currents goeth where they listeth and no man knoweth where that ith. Sometimes you're better off letting the shield float; you just have to stay loose and see what works best.

Some preamps have to be laid out with the output next to the input, usually to match other equipment or to pick up the connector, or for some engineering but non-theory reason. Here you have to use a solid tube, with either a coax wire or even a balanced pair in it, to take the output back to the connector. Just like anything else, you just do the best you can with what you have. But isn't that where it's at? ■

Retire to a Ham Heaven

-- how to go on a permanent DXpedition

George Brumley KØWTM/OA6CV
Apartado 825
Arequipa, Peru

Most of my rag chewing is done with hams in the States and the most common subject is, "What do you do when you retire and where do you do it?" We usually get started when the stateside fellow says, "Uh, you sound like an American; I mean like you're from the States. What are you doing down there? Maybe in the copper mines or in the oil business? Or a missionary?"

"I'm retired, old man; I came down here to live over four years ago, in July of 1972." That usually brings on some other questions: "Well, say now, that's interesting. Do you have friends down there? What made you pick Peru?" Now that I know the man is interested and not just making conversation, I give him the details.

My wife and I went to Africa, to Ethiopia, in 1952, and I built a 31 meter broadcast studio for Haile Selassie. I had the privilege of being on the air as ET3GB most of the seven years we were there. We loved Addis Ababa, high up in the mountains and with all the tropical fruit you could eat in the greatest variety. Living was cheap there in those days. We always said that if we could afford it when I retired, we'd go back. But when the time came, our three children (all born in Addis Ababa, by the way) were getting old enough to think about getting married and we hated to go so far from the States. (The girl is married; the boys are still thinking.) So, we decided to go to South America, even if it meant learning another language. I was 53 and the XYL 54. We had friends in Quito, Ecuador and Arequipa, Peru. We wrote several letters to both places and finally chose Arequipa.

Does that mean that we "just went down there"? Yes, it does. And no, I did not fly down first or visit first and find out about Arequipa. I trusted my friends and read everything I could find in the library in Wichita, Kansas. Then we had a garage sale, sold off everything we could, and gave away the rest. What we couldn't part with we put in six (six!) big crates and shipped them down by sea; we got on a plane and flew to Arequipa. Admittedly, that is not the way I would recommend to someone who has never lived in a foreign country. But we had lived in Ethiopia for seven years and we *knew* there is only one United States of America. Those who expect to go to a foreign country and find conditions just like those in their own neighborhood are in for a shock. But the surprises can be nice pleasant tingling sensations, too.

"How's the weather down there?" Well, friend, we have the weather that California and Florida brag about; sun every day. It hovers around 65 degrees day in and day out and doesn't vary more than about 10 degrees from the hottest to the coolest of the day. Arequipa is about 8,000 feet up in the mountains in the desert part of the Andes. A lot of people have loved this place; the city is about 450 years old and has one of the oldest universities in this part of the world. The sun gets a little hot during the day, but just walk over to the shady side of the street; a bit of breeze will be blowing and you'll almost feel as though you had walked into an air-conditioned store. Most of the natives carry or wear a light sweater. Use it if you have to stay in the shade and take it off if you're in the sun. The poncho is very popular, of course.

With the population explosion, housing can be a problem, but we do very well. A friend owns a huge house here but is living and working in the States. We have six bedrooms, a small fruit orchard, and a private swimming pool. The roof is a huge place, and that's where I have my beam, of course. It's easy to let down and play with. It's on a telescoping mast. The rent? Please don't cry . . . it's less than $100 and I can't tell you how much less but I don't mean what the advertising people do ($99.95)! And no . . . we didn't know about this house deal until we got down here.

Those who have had diplomatic or military assignments overseas and are used to eating out of the commissary should be careful about going to a foreign country to live on their own. It ain't the same! And those housewives whose main kitchen tool is a can opener will soon find themselves asking for a bigger food budget. Canned food is high and there are no TV dinners. But those who like to cook from scratch will find plenty of "scratch." Most foreign housewives go to

The author with more than 100 QSLs. About 150 countries are confirmed, but some of the rare ones insist on sending odd size cards that won't fit the plastic holders.

The XYL, Lucille, likes living in a foreign country, too. She likes all the pretty stamps I get on DX QSLs.

market every day and bring home fresh fruits and vegetables to cook. This is what the French cooks emphasize and they are supposed to be the best in the world. We have everything to eat the North American has, besides all the delicious fruits of the tropics such as papaya, mango, guava and delicious bananas ripened on the tree. You wouldn't believe these after eating those picked green and allowed to ripen while on their way north.

Although there is TV in all the world, we have been weaned because all the programs are, naturally, presented in Spanish. So when the band folds, we read or play cards or develop pictures or generally enjoy ourselves as in the old-fashioned pre-TV days. However, many of the TV serials from the States are presented here with Spanish dubbed in. It's a way to learn Spanish if you're a real TV fan. My youngest son is a TV fan and now speaks such good Spanish and did after only a couple of years that his young Peruvian friends sometimes ask him, "What part of Arequipa were you born in that I haven't met you before?" Or, "Your mother's Peruvian, isn't she?" Well, "Then your father is from Peru?" No, he was 14 when he came down here and he speaks Spanish in a perfect Peruvian way, absolutely idiomatically. But if there isn't an unusually interesting program on and we are tired of cards and reading, we go to a movie. It seems that at least half of the movies are from the States and in English. And the most expensive ones are less than a dollar and the cheapest a fourth of that.

As you may know, the US has reciprocal amateur radio agreements with dozens of countries and Peru is one of them. There probably will be more in the future since the obtaining of a license in the States by foreigners has been simplified and made more liberal. To get a license down here (and in most foreign countries, that is), you should have your own original license from the States and about a dozen photocopies. The process may take three months, but the speed with which most Americans get their ticket from the FCC leaves us little room to grumble. You'll also need a passport and usually some other papers which you can only obtain after you get there – a police certificate, for example, showing that you actually reside at a certain address. You need all of this if you plan to stay in South America for any length of time and operate. If you're just flying down, the best thing to do is write to the radio club in the capital of the country you plan to visit and ask them to help you get a temporary license. Write at least three months before you plan to leave and send along some IRCs. You'll get some forms back in a language you won't understand, but then how many of us can understand the forms Uncle Sam spews out at us every week? Don't we usually have to take them to some office and get official help? So when you get the forms back from the foreign radio club, take them to your friendly high school language teacher and let her put her ability in the language to a real test. Fill out the forms with the help of the teacher or someone else qualified to understand the language and send them off with the required fee. This means an international money order, not your personal check.

Sometimes you get a nice surprise. I did everything outlined in the previous paragraph but didn't get a reply before I planned to leave, so . . . I just said "Get on board, li'l children" and we flew down anyway. When I got to Lima I managed to find the man who was handling the amateur licensing and he personally typed out a temporary license for KØWTM/OA6. So, I could get on the air immediately. Only one little problem: I couldn't get my gear out of customs and didn't get it out until the temporary had expired some 90 days later. But there is an arrangement now to prevent such tragedies. You write to CARNET BUREAU, United States Council of the International Chamber of Commerce, 1212 Avenue of the Americas, New York NY 10036. The CARNET (pronounced kar-nay) is a little paper like a passport or vaccination certificate for your ham gear. So when you get to the foreign port of entry, the customs man takes a look at

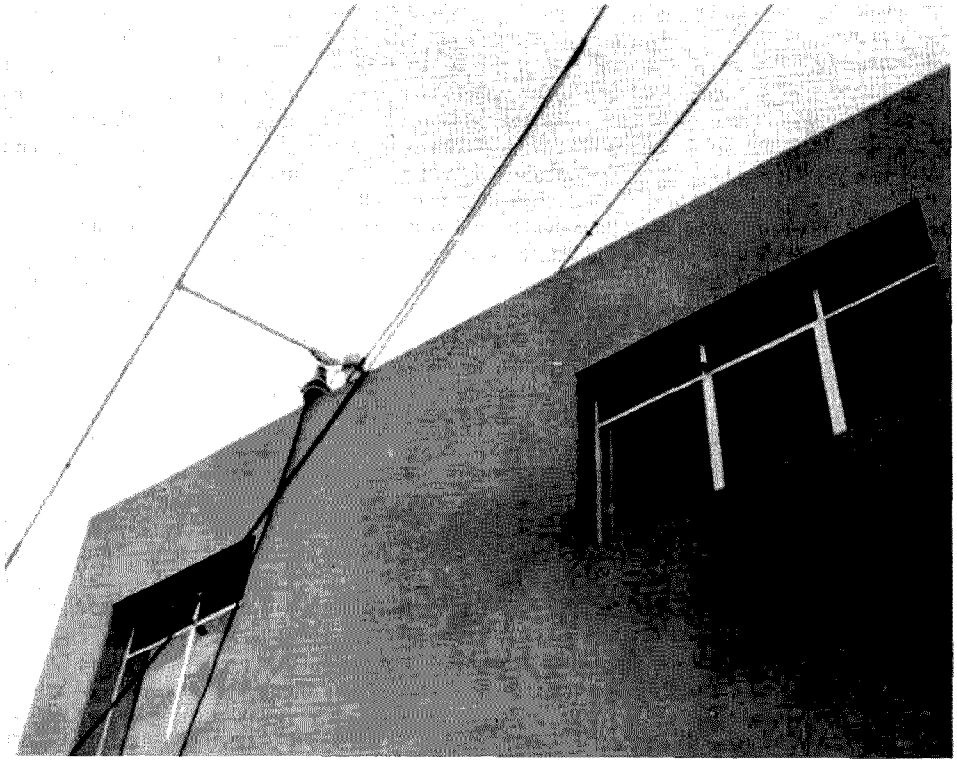
Cleaning up the dishes after a cookout on the patio is no trouble at all if you have a "dishwasher." Our maid costs less than the automatic model you use.

your little CARNET and looks at your equipment and you walk right on in. At least that's the way it's supposed to work. The CARNET is good in 30 countries and with it you aren't suppose to pay customs or post a bond to take your equipment into a country temporarily.

What kind of equipment you take to your foreign hideaway retirement place will depend on a lot of factors, like money and what do you have now. When I knew I was coming to Arequipa, I sold a perfectly good Swan 500 so I could get a Heathkit SB-102. Not that one is better than the other, but I wanted to know as much as possible about the rig I was going to depend on for my hamming. If a rig develops a problem, it is very probable that you are going to be the one to fix it. Sending it out of the country to have it repaired will drive you to drinking . . . the customs hassles are unbelievable. And forget that "send in the card that's bad" bit, too. If everything goes well and a friend hand-carries the card to the States and another friend hand-carries it back, you still might be off the air a couple of months. So *know* as much as you can about the rig you're going to be using. While we're talking about it, remember such simple things as voltages and line current frequencies. The rig should be able to work on 220 as well as 117 and on 50 as well as 60 Hertz. And that "220" may well be as low as 190 or as high as 250, so keep that in mind, too. You need a rig that's not fussy about what it feeds on.

A linear is nice but most people in the world don't use one . . . as a matter of fact, most hams are limited to less power. You won't find it a big disadvantage if you don't have one or can't afford to bring one along. But you will need a good antenna. In South America, in many countries, the houses have flat roofs. I can't resist trying out beams when they are so easy to get to. I built a homemade 3 element, 3 band quad and put it up on two 10 foot sections of TV antenna tubing I bought locally. For a motor I have a big heavy Ham M. But though there is a little breeze most of the time in Arequipa, strong winds are a rarity and I never had a bit of trouble with it. And what a joy to put the swr meter at the right end of the coax or use the grid dip meter where you should use it . . . right at the antenna. Yes, I brought those two simple instruments and an old Simpson along. The grid dip meter is the first of that kind of instrument that Heath brought out years ago. The tube in it has never been changed though I've shocked the daylights out of it a time or two. It's made for use on 117 volts, but twice I've plugged into 220 and was intently measuring away when I realized what I had done.

You'd better bring along your own coax. You can get wire and insulators and you can find someone who can weld together TV antenna tubing for a boom and mast for a quad, if that's your taste, but as for a balun and coax – better bring your own. If you have a 12AVQ, you might enjoy that. I brought a 14AVQ, but the 40 meter band in South America is shared by myriads of shortwave broadcast stations and it takes a lot of courage and



I'm currently using a 2 element triband yagi. What looks like a middle element is the coax from my 80-40 doublet.

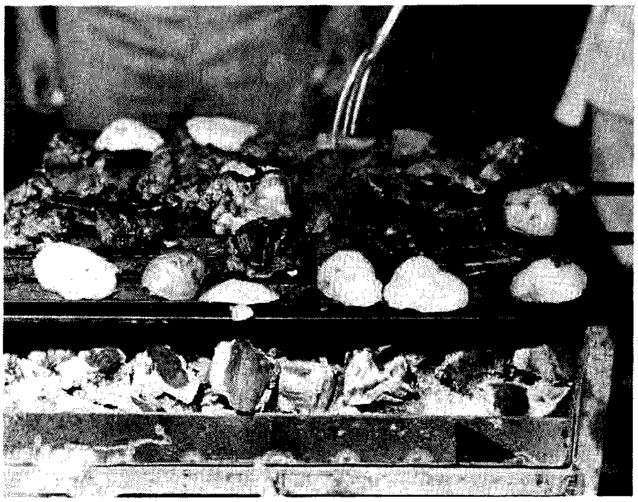
peculiar ears to separate the hams from all the crud on top of them. The old vertical works pretty well on 15 and 20 and I've had some use out of it on 10. The 75 meter band down here has a high noise level . . . as far as I'm concerned. The S-meter needle is usually right up there at S-9. However, I have a 75 meter dipole up and I tune across the band from time to time. Once in a while, fantastic things happen. I worked Iceland and South Africa within 15 minutes of each other one night. I often hear stateside signals, but you'd be surprised at how few people are interested in listening for a weak DX signal on 75 or 40. A linear on those bands is a real help.

But on 15 and 20 you can find lots of DX and have all the fun a retired ham's heart can stand. Assuming that, as an American, English is your native language, you'll find that is a big advantage. Most of the DX stations will be speaking English and if you'll learn to speak slowly and very distinctly . . . even exaggerate the pronunciation of the syllables . . . you'll find that you'll work lots of DX. (This will make up for that lost feeling the first few months when you go shopping and find that people look at you uncomprehendingly when you try some of those carefully rehearsed phrases on them.) And working the DX is just the first part, of course. You won't have to beg for cards; you'll find that people will be sending *you* cards with IRCs and begging *you* to send them a QSL.

And you'll learn some other things about QSLing. Some guys will send you a card via the "burro" and will include some IRCs. The card will finally get to you some six months later but it won't be in the envelope. The "burro" will have opened the envelope, taken out the IRCs, stamped "Courtesy such and such 'burro'" on the QSL and sent it along with a lot of

A cookout given for a group of commercial radio operators. Many are showing interest in getting on the air for fun as hams.

others. Perhaps you'll never know the card was sent airmail or that the other fellow sent you some IRCs unless he mentions it on the card he sent you. But he expects to get your card back within a month or so. It doesn't work that way. He's probably swearing at you when he thinks of how that DX station (*you*) just kept his IRCs and didn't send a card back. So, one of the things you can truly enjoy when hamming from a more civilized DX location (rather than some uninhabited rock) is sending back QSL cards. I always say that I need at least *one* IRC to send a card back airmail. If you're retired and do much hamming, you'll go broke if you try to pay for all the cards. Even sea mail mounts up. So give the other fellow your mailing address (get a PO box as soon as possible) and tell him for quick results, send you some IRCs.



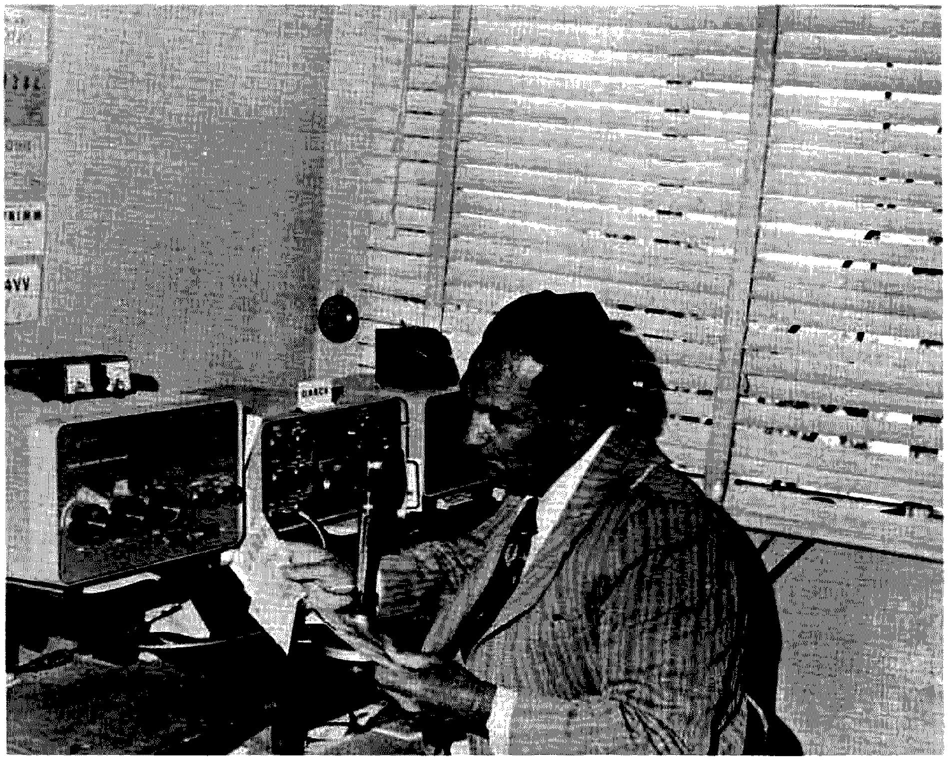
You're looking at young lamb and pork bought from the Indians out in the hills. The grill is homemade — welded in a friend's shop from scrap he gave me. Won't you come down and have a meal with us?

Since most XYLs are not hams, what will the wife be doing while you're having a ball with all this hamming? First of all, let me say that many, many countries in South America have third party agreements with the US and you'll be rather surprised at the interest your wife will begin to show in hamming after you get her in touch with all the kids and perhaps some relatives or friends she hasn't seen or written or talked to on the phone for years. I've been a ham since 1938 and my wife and I have been married for almost 35 years. Hamming has always been something she could definitely leave alone. But now she often says to me, "Why don't you see if the band is open to the States?" Or, if she hears me talking to someone in or near a city

where friends live, she says, "Ask the man if he has a phone patch." The way most people correspond today is not by letter . . . they'd rather pay a five dollar phone bill and talk to you personally than to take thirty minutes or more to write you a letter and then wait a month for you to get around to answering and have it get to you. So, your wife is going to be much more interested in hamming.

But what else can she do? Why should she let you drag her off to Timbuktu? If she has an ounce of "do good" in her, it can grow to full bloom. A nurse or a nurse's aide is really welcome in most of the so-called "underdeveloped" countries. She would be welcome in most any hospital, and though there aren't many orphanages, she would be welcome there, too. There's nearly always an American "Instituto Cultural" run by the US State Department and teaching English is a big thing with them. She won't need a teacher's certificate or even a high school education. They'll be so glad to have a "native speaker" that they'll show her just what to do and put her to doing it quickly.

But besides what she can do for them (it really is more fun to give than to receive, but some people never find that out), there are things the South Americans can do for *her*. There are usually several shops in any given city where guitars are hand made. They won't look as shiny and finished as a Gibson or Fender or what have you, but you'll be surprised at the beautiful sound they can produce. Haven't you always wanted to play the guitar? Well, you'll have a chance for lessons two or three times a week for what it would cost for one lesson in the States. You won't learn "cowboy" style nor "Beatle" style but remember, it was the Spanish who invented the guitar. You can have private lessons or join a class. You'll be practicing your Spanish and having a lesson at the same time.



OA6CV admiring some new QSLs just in. One IRC gets you an airmail QSL in the States. Turn-around is usually 24 hours.

Buying dresses off a rack is not so popular as in the States. If your XYL likes to sew, she'll find plenty of material, though she'd better bring her own sewing machine. Or she will find plenty of people who can just take a picture of the latest style and turn out an exact copy of a "Paris fashion" from it. The beauty shop bill will drop to next to nothing . . . or maybe it won't. She'll get over saying, "I wish I could afford to get my hair fixed more often."

You thought I was going to leave out your aches and pains, didn't you? Well, if you're truly infirm, you'd better stay home. But you can get good medical treatment in any large city in South America today. And you'll find that in most of them there is a doctor who speaks English and has had some training in the States. Your Blue Cross and Blue Shield won't mean a thing down here, and probably none of the other health insurance schemes will either. (Check, if it's a point with you.) But on the other hand, medical service is so cheap in contrast to that in the States that what you've been paying in premiums will probably take care of about anything you need. You might even be surprised at what you have left over from the money you set aside for medical bills. But if you need a special diet or special foods or a chiropractor, better stay home. On the other hand, if you're a reasonably healthy man for your age and have no unusual problems, don't miss out on all the fun worrying about what you're going to do when you need a doctor. Have a good checkup and ask your doctor what he thinks about your leaving the States.

What about education, if you still have some children in school? My daughter had graduated, but my two sons were still in high school when I took them out and brought them down here. What is education, anyway? Isn't it supposed to fit you for life? While we were uneasy about it at the time, my two boys now are very happy I brought them down here. They have learned to look at the basics of life and have participated in life at an early age. They now know two cultures. They speak Spanish far, far better than the usual high school or even college teacher of it. They read and do some studying on their own and when they went back for a vacation to the States, they took the GED examination and now have the equivalent of a high school diploma. If they want to go to college, I feel they will do better than if they had continued on in high school rather than come down here. It's an opinion, of course.

Part of the fun of working DX is thinking about where the ham you're talking to lives and how it would be to visit or live there yourself. But I can't answer all the questions or discuss all the angles even if Wayne Green invited me to expand this into a "Handbook For The Retired Ham Who Wants to Go THERE And Enjoy the Next Sunspot Cycle." But if

you'll send me your questions and doubts and a check for a couple of bucks to pay for the stamps and a cold beer while I'm typing out my comments, I'll be glad to help if I can. To travel you'll need a valid passport and getting an International Health Certificate is a good idea, too. They don't ask for them all the time any more, but you don't want to be in quarantine even a few days. So get it. And you might want to drive, so get your local auto club to get you an International Driving License. They'll do it even if you aren't a member. And for heaven's sake, get that CARNET for your equipment. You do want to ham, don't you?

Just because you've been told these are the "golden" years, it doesn't mean that you can hoard them. The days go by just as they always have and what matters is what you do with these years. If you've always wanted to ham from some exotic place I'd be glad to help you realize your dream. But if you don't . . . I don't want to talk you into something you'll regret. I've never wanted to run a hotel, but if it would help you decide, I'll be glad to have you and your wife come down and stay with me for a week. I'll charge you a hundred dollars and you'll have to eat Brumley home-style meals and generally entertain yourselves. You can use the rig. Your bedroom will be simple and you'll have to look after yourselves . . . you'll have a private bath. But don't just come down; write beforehand. There just might be two couples that want to come down and I'd rather have only one at a time. I only have one rig and I want to use it myself, too. Or, send me a letter with your questions. Come on, OLD MAN, don't just sit there and dream and wish. You can do it if you want to. Wake up and live the rest of your life! ■

Hamming the Buggy Sweepstakes

-- ham public service rides again

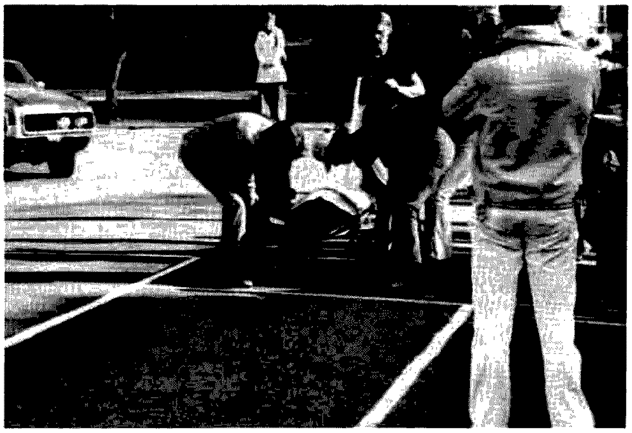
Photos by Glenn Meader

"And the *Streak's* ahead, followed by the *Delta Queen,* and the *Flying Buttress* is a close third. Around the turn of the chute, it's . . ." No, it's not a car race; it's the annual running of the Buggy Sweepstakes at Carnegie-Mellon University, and amateur radio was there.

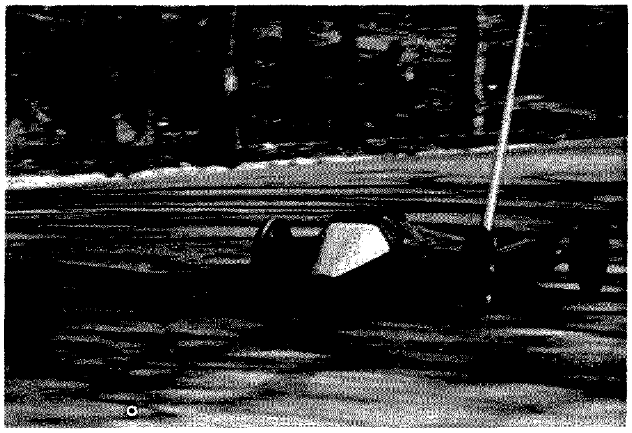
Sweepstakes is the descendant of the 1920 interfraternity push-mobile race held on the Carnegie Tech Campus. Things have changed since those ponderous contraptions (one a bathtub on wheels!) rolled; today's buggy is computer-designed, costs upwards of $1500 and incorporates modern features. The buggies of Delta Tau Delta, for example, sport fiberglass monocoque shells, torsion bar suspension and pneumatic tires. This isn't for naught, as the best-designed buggies (engineering, appearance, safety, and special features) receive trophies and generally run better in the race, too.

Sol WB9IHC, "Course Closed!"

Andy WA2UDS, "Course Closed!"



The starting line — "Ready, Set, BANG!!"



Free-roll.

The Course

The race is run on Pittsburgh city streets. The buggies are pushed up a 5.9% grade from the starting line to the free-roll, 2400 feet of downhill, curving road. Turning the hazardous "chute" at speeds upwards of 45 mph, they again travel uphill, being pushed to the finish line. The entire course is 0.84 miles, and the record time (set by Pi Kappa Alpha in 1975) is 2:19.3.

Naturally we wouldn't want cars on the course while the buggies are running — imagine what a 2 ton car would do to a 175 pound (maximum, with driver) buggy! Up until last year a car with a signal flag would circuit the course prior to each heat, indicating to the "flaggers" stationed at each intersection that the course should be closed to traffic. This system had many problems, one of which was that there was no way to inform those in authority if a car ran a barricade, nor was there any way except sheer guesswork for the flaggers to know when to open the course.

Enter Amateur Radio

These problems disappeared when the Carnegie Tech Radio Club (W3VC) began providing communications for the practice sessions held at 6:00 am Sunday mornings. Two meter FM units operating on 52 simplex were stationed around the course with the flaggers, and a command post was established within easy earshot of the sweepstakes chairperson. Three minutes prior to each heat the "close course" was radioed to the flaggers, and each unit would respond by confirming "course closed" status. While buggies ran the course, their position was constantly relayed to the sweepstakes chairperson, and once they cleared the course, she authorized course opening.

Accident!

Buggy accidents can result in serious injury, so the CMU Security Van-Ambulance is kept at the chute at all practices and race days. During the practice last April 1st, a buggy's steering malfunctioned, sending the buggy careening into a tree. A quick radio call brought the ambulance to the scene, and an autopatch call over WR3AGJ alerted the hospital of the incoming patient. The driver was not seriously injured, but doctors at the hospital felt that if he had not arrived as quickly as he did, there may have been serious complications.

Race Day(s)!

April 9 and 10 marked the climax of the combined efforts of the many organizations racing — SWEEPSTAKES! Our setup was the same as that used at the practices, with the addition of a motorcycle unit (WB3AWT) and judges/backup communications provided by the CMU Ranger Company. Ever compare a HT to a PRC-77?

The timers on the judges' truck (HQ) required the starter's countdown and gunshot, so this was broadcast by the unit at the starting line. The Security Van, at the chute, was equipped with a PA system which was used to amplify the starting count for the benefit of the spectators there. Race times and other data were also announced in this manner.

Conclusion

The entire Sweepstakes ran smoothly, and for the first time in years, there were no accidents at all. Much of this has been attributed to the fine communications

The long hard push to the finish line.

The crew (l to r) – John WB3AWT, Karl WA3GSB, Andy WA2UDS, John WA2ZUL, Reed WA3JBQ, Connie W3HTL, Sol WB9IHC.

provided by W3VC.

Club members John Rose WA2ZUL, Sol Marcus WB9IHC, Karl Sieber WA3GSB, Don Gregg WA3KGT, Connie Hilpert W3HTL, Steve Salgaller WA3ZGT, Glenn Meader, Andy Funk WA2UDS, and Pittsburgh amateurs Reed Krenn WA3JBQ and John WB3AWT devoted their time and energy to the project, making it a success. A special thanks to Jerry DiGennaro and the members of the CMU Ranger Company for their participation.

This year the Carnegie Tech Radio Club will provide communications for Sweepstakes 1977, and everyone is invited to come down and watch the races or help out.■

Taming the Wild Beta

-- how to make transistors behave

Transistors, like the ladies, are rather variable, and while the variability of the tender gender may be the spice of life, with transistors this can be just another electronic pain in the epizootic.

Getting sound through the average low powered stone, such as is used in mike stages or other moderate level use, can be a problem when you realize that transistors of the same type number by the same or different manufacturers may have a current gain variance of about 150% or more.

This means initial design problems or troubles when you go to replace a transistor in an already functioning piece of gear and find either too much or too little gain is being produced by the new unit.

A basic approach around this problem is to tackle it from the idea that the circuitry associated with the transistor might be rolled in such a manner that it could ignore the wide differences in transistors plugged into it.

Fig. 1 shows a unique transistor manufactured by the "Anybody's Transistor and Pool Table Mfg. Co., Ltd." It is NPN, will stand up to a 25 volt supply, and is rated at a few hundred milliwatts dissipation. Its beta or current gain is "tightly held" to a tolerance of between 40 and 200.

One key to the circuit is the lack of an emitter bypass capacitor which produces current feedback. Now for some basic rules of thumb that are not exactly gospel, but have enough latitude to make them work in a practical way.

1. Keep your supply voltage between 9 and 20 volts.
2. Make your emitter resistor at least 470 Ohms.
3. R2 should be about ten to no larger than 20 times the value of your emitter resistor.
4. You should have about 1.0 volt across the emitter resistor to ground. (One way of doing this is to utilize RX shown dotted in between the supply and the emitter resistor. Adjust the value of this resistor so that you do get about one volt from emitter to ground, which will solve your problem.)
5. You select your stage voltage gain simply by multiplying your selected emitter resistor by the wanted gain and using that product as the value of your collector load. Example: Emitter resistor=470 Ohms. Stage gain of ten wanted. 470 times 10 = 4700. So collector load = 4700 Ohms.
6. You can select the value of the R1 top leg of the base bias divider by making it a value that will give about one half the supply volts from collector to ground.
7. You should try to keep the base divider current in the 0.1 to 0.2 mil range. The lower values will tend to give lower circuit noise.
8. On a practical basis, try to keep R2 to 15k or less.
9. On a practical basis, the collector load should run between 4700 and 15k, the higher values for use with higher supply voltages.
10. You can assume that your undistorted output voltage (distortion 1% or less) will be about 20% of your supply voltage.
11. You can assume, on a practical basis, that your input impedance will be the value of the resistor from

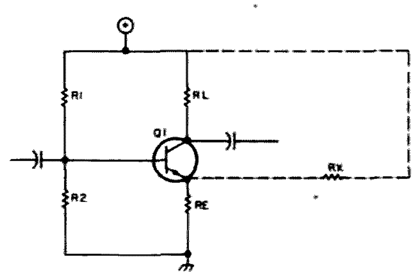

Fig. 1. If your circuit dc conditions are all OK but the emitter to ground voltage is too low, insert a value of RX, as shown, that will bring the emitter voltage closer to the desired one volt target value.

base to ground.

12. You can assume that your output impedance will be the collector load in parallel with the input impedance of the following stage.

13. If your final design does not show a measured three volts or better measured between collector and emitter, fudge your values until you do get close to the minimum three volt figure.

If we follow this series of approximations, what do we wind up with? We should have a circuit that will accept almost any transistor with reasonable approximations of the selected type and give stable gain and stable operation for the range of temperatures that a piece of ham gear might experience in a car.

This would run from freezing in the winter to perhaps 150 degrees in a closed car in the summer sun.

We have two types of stability we are really considering. One is circuit gain or ac stability, and the second is changes in circuit operation with changes in dc conditions in the circuit. This last item is particularly important to you fans of the nine volt battery. These circuit guesstimations should let this type of stage operate down to a six volt throwaway point, or well below the point where any associated power stages would have called for a new battery.

The basic factors for ac stability are the existence of the emitter feedback resistor and the ratio of the emitter resistor to the base to ground resistor. The basic dc stabilizing factors are the effect the bias divider has on swamping out changing base current and, again, the dc effect of the emitter resistor in keeping the base to emitter voltage reasonably constant with changes in collector current. ■

A Combiner for Your 2m Whip

-- BC reception on your 2m antenna

Fred Johnson ZL2AMJ
15 Field Street
Upper Hutt, New Zealand

The article "The Secret 2m Mobile Antenna" on page 44 of the May issue of *73 Magazine* brings to mind a similar unit that I have been using for some time. My requirement was the opposite of that of the article – in my case, to use the one 2m antenna for the 2m transceiver and simultaneously for the AM car radio.

The 2m antenna is a five eighths whip with a loading coil at the base. Fig. 1 shows this coil as L1.

Installation and operation of the splitter unit is a piece of cake. The coax lead from the antenna to the 2m transceiver is broken at some convenient point and the components C1 and L2 inserted in series with center conductor. C1 is adjusted for maximum signal on the transceiver S-meter. No change in the 2m transceiver performance will be noticed.

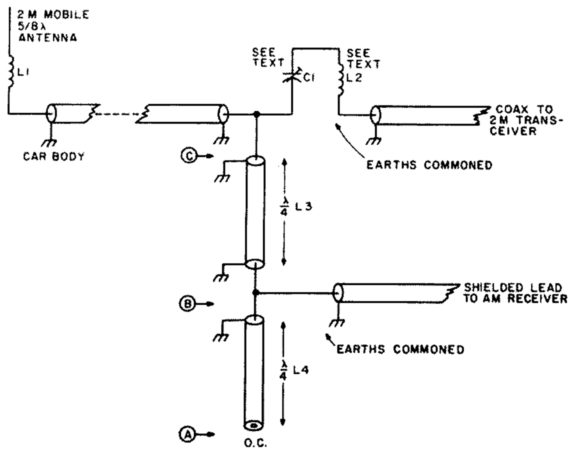

Fig. 1. Diagram of combiner unit for operating AM receiver simultaneously with a 2m transceiver off a 2m antenna.

The AM antenna lead is taken off via a quarter wave stub arrangement. The stub L3 is connected to the antenna side of the C1/L2 assembly. An additional stub L4 is connected to the free end of L3. The AM receiver lead is connected to the junction of L3 and L4. The free end of L4 is left floating with the inner and outer on open circuit.

The operation of the 2m quarter wave stubs is such that the open circuit at A puts an effective short circuit (for the 2m signal) at B. This short circuit at B puts an open circuit at point C. So the 2m signal from the antenna arrives at C and sees an open circuit when "looking down" L3. It sees a low impedance path looking towards the 2m transceiver because C1 and L2 form a series-tuned circuit at resonance. The result is complete isolation of the two operations on the one antenna – 2m mobile with AM music in the background if required.

The five eighths wavelength antenna must be of the variety with a series loading coil at its base (i.e., not the type with a grounded parallel-tuned circuit with a tapped feed). Note that there is a dc path from the AM receiver right through to the antenna.

The coax lengths L3 and L4 depend on the type of coax used. Either 75 or 50 Ohm is suitable. I used solid dielectric type with a velocity factor of 0.66, so the lengths L3 and L4 are each 12.5 inches. C1 is a 27 pF trimmer. L2 is 3½T, ¼ inch diameter, ½ inch long, #18 wire. Both these components should be mounted in a small box to effect good screening.

This combiner has been very effective and certainly improves the appearance of the car (from the XYL's viewpoint, anyway) by reducing the antenna complement by one! This also means that the original AM radio antenna can be replaced with something more useful – such as a collinear for 432!! ■

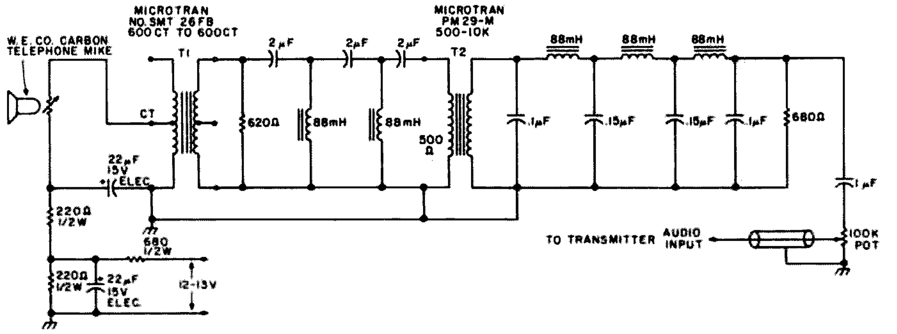

Fig. 1. Unless otherwise specified, all capacitors are non-polarized, preferably Aerovox type V146R aerofilm mylar caps.

The Carbon Marvel

-- best mobile mike yet?

A carbon microphone is one of the most reliable forms of a voice transducer. The carbon microphone can be made to sound natural and, in most cases, the listener will not know one is being used. Listen to a YL on an autopatch; the voice sounds very natural and it is fed into the transmitter via a telephone. Ma Bell has to accommodate many services and, therefore, has given much attention to the carbon mike — in particular to the manner in which it is incorporated into telephone circuits and to the acoustical response of the device.

Carbon microphones can take a fair amount of mechanical punishment. Great excursions in temperature do not degrade their operation and, best of all, they are cheap. They are found in abundance on the surplus market. They make excellent mobile microphones.

This type of mike requires a small exciting voltage. It is a variable resistor which varies the exciting voltage at an audio rate. The audio response is determined by the mounting of the carbon button to its acoustic resonator. This is the diaphragm and cavity in which it is mounted.

The output of the carbon mike can then be directed into a filter which enhances a useful response range, 300 to 2800 Hz. The name of this game, however, is to match the mike to the filter in a manner which prevents or reduces the variation of impedance caused by the change in microphone resistance.

Let's look at the circuit in use at W1SNN. The carbon mike output is directed into an audio transformer. The excitation voltage applied to the microphone is reduced from 12 volts, usually supplied from a car battery.

A hash filter is incorporated with a voltage divider, which serves to keep the alternator whine from my Maverick out of the audio system and to reduce the battery voltage to 3½ volts. It is important to try to maintain the exciting voltage in the 3 to 3½ volt region, since increasing it above the high limit will allow the characteristic "frying" sound produced by the carbon granules to become objectionable. When transformer coupling is used, a current limiting resistor is required to insure that the current flow will not bias the transformer core too badly and destroy its frequency response. The 220 Ohm resistor in series with the divider/hash filter will keep both of these effects to a tolerable level.

The secondary of the microphone transformer is terminated in a fixed resistor, allowing the two section high pass filter to "see" a constant termination regardless of impedance reflections given by the microphone. The high pass filter output feeds into an impedance matching transformer, which is followed by a three section low pass filter.

The overall response of the combined filters depends upon the fact that load impedances must be constant, so the output of the last filter is terminated in a resistor. A potentiometer ac coupled to the output acts as an audio volume control. This control may be eliminated if one exists in the transmitter. However, remember the output of this microphone filter combination is in excess of .250 mV and is far more than required for most microphone input circuits. At W1SNN this microphone is used to generate direct FM by feeding it into a processed audio system incorporated in a frequency synthesizer. Very little audio is required and hence the pot. The response of the microphone and filter combination is such that it cuts out the low frequency rumbling produced by mechanical sounds of my vehicle in motion and the higher pitched undesirable traffic noise.

Since the audio level is kept quite low, the mike must be held close to the operator's mouth. The reduction of speech slurring from breath sounds and the overall improvement in the sound of the rig make the addition of all this circuitry worthwhile. ■

The Minicom Receiver

- - finally, a QRP allbander

Does 5 bands, noise blanker, S-meter, tunable CW filter, internal speaker, and ac/dc operation in a receiver small enough for suitcase or attache' case turn you on? If so, then the MK IV may be what you've been waiting for.

Background

The Minicom MK IV is a miniaturized solid state communications receiver, and it should be apparent from the title that there have been 3 predecessors. I guess the earliest version was one I included for illustrative purposes in my article on the LM-373.[1] The real MK I, however, did not appear until 1974 when it was published as a construction project.[2] The MK II was devised during the time the MK I was awaiting publication and, since it was very similar, no

The MK IV makes an attractive package.

attempt to publish details was undertaken. Instead, all readers who inquired about the MK I were advised of the later version. The MK III appeared in print together with a collection of circuit ideas for receivers.[3] It was different from the others in that a triple varactor was used to replace the 3-gang tuning capacitor in the rf section. As with all previous Minicoms, single band operation on 80 meters was standard.

At various times I attempted to design a converter that could be mated with the Minicom assembly to produce a multiband receiver of diminutive proportions. The converter usually ended up being larger than the receiver and success eluded me for a very long time. By using 3 separate PC boards and constructing the converter around and between the wafers of a surplus rotary switch, a suitable converter was finally evolved which led to several copies of multiband Minicoms in the same size cabinet as the single band MK I. Construction of this converter, however, was far too tricky and the rotary switch too hard to come by to make publication of details practical.

The MK IV

Over a period of many months, I investigated the offerings of several switch manufacturers to see if a converter design could be developed that would be suitable for publication. The Stackpole Series 80 subminiature rotary switch offered the most promise, so I ordered some samples fabricated to my specs. The switch has printed circuit pins so that the 2 boards used for the converter mount right to the switch. Pins from various sections are brought out on opposite sides so that the 2 boards form a sandwich with the switch in the middle.

The converter together with 2 other PC assemblies make up the bulk of the receiver circuitry. A third board constituting an ac power supply completes the lineup. Everything is housed in a Radio Shack #270-254 cabinet whose dimensions are 6 ¼" x 2 ¾" x 7 ¼".

The main PC assembly contains the tunable i-f which covers 3.5 to 4.0 MHz, a noise blanker with threshold control, and 2 amplifier stages. Selectivity is provided by 2 transformers and 2 dual ceramic filters at 455 kHz. The companion board houses the detector, AGC circuits, S-meter amplifier, BFO, tunable CW filter, and audio power amplifier. Both of these boards are 2.4" x 5.5".

Power required is a positive 12 volt source capable of supplying 120 to 150 mA during audio peaks. No-signal drain is about 80 mA for SSB/CW operation. The internal regulated supply meets these requirements and is automatically switched off when the receiver is switched to an external dc source.

There are 8 operating controls and 3 switches on the front panel as well as an S-meter and phone jack. The controls are main tuning, rf peaking, AGC time constant, rf gain, af gain, blanker threshold, CW filter tuning, and BFO tuning. Switch controls consist of the bandswitch, AM-SSB/CW selector, and CW filter mode switch. The ac/dc power selector switch, antenna connector, ac power cord connector, and

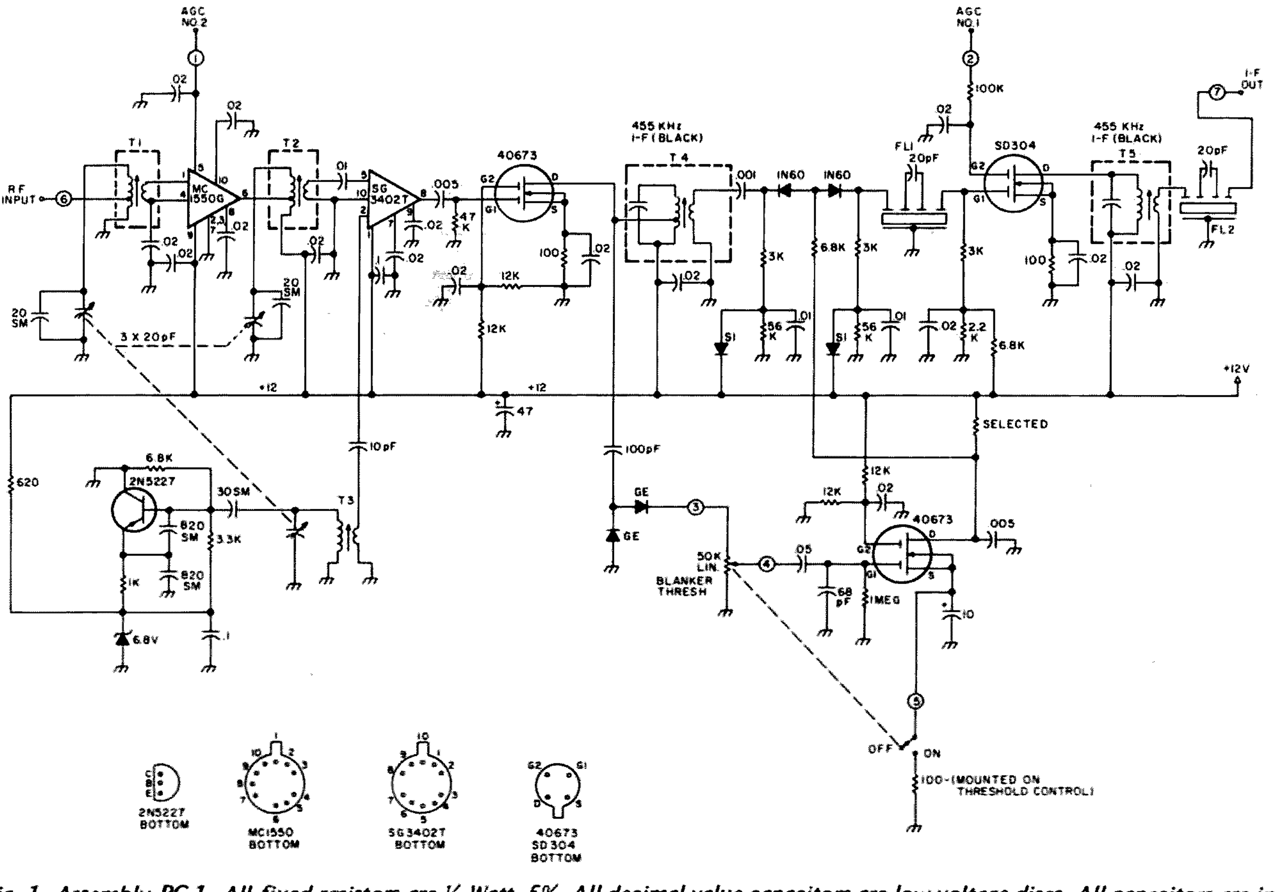

Fig. 1. Assembly PC-1. All fixed resistors are ¼ Watt, 5%. All decimal value capacitors are low voltage discs. All capacitors are in uF except as noted on schematic. Capacitors with polarity marked are electrolytics of at least 15 volt rating. All SM (silver mica) capacitors are in pF. The circled numbers denote pads on the PC board which connect to external points or controls. The artwork layout in Fig. 5 shows the physical location of each of these points.

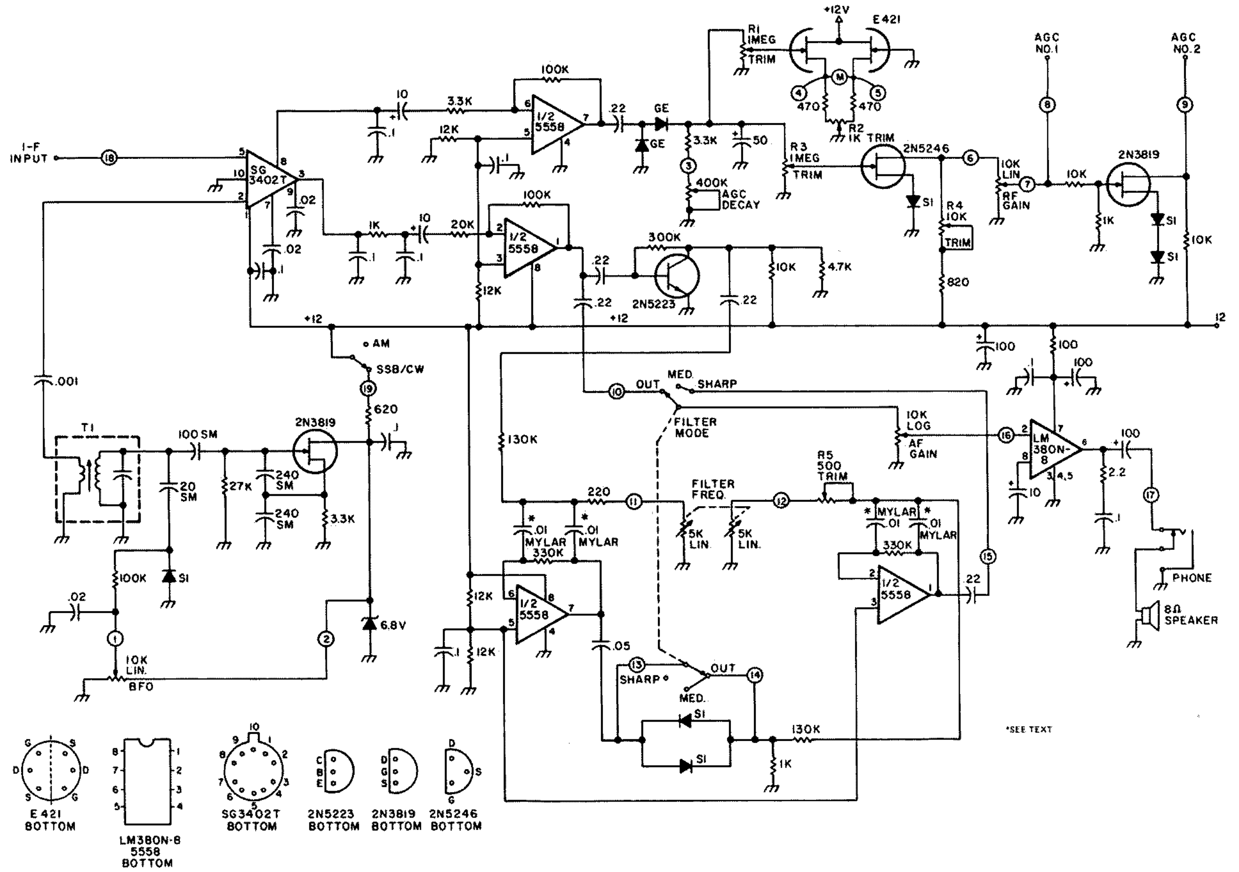

Fig. 2. Assembly PC-2. All fixed resistors are ¼ Watt, 5%. All decimal value capacitors are low voltage discs and values are in uF. All capacitors with polarity marked are electrolytics of at least 15 volt rating. Capacitors marked SM (silver mica) are in pF. The circled numbers denote pads on the PC board which connect with external points or controls. The artwork layout in Fig. 6 shows the physical location of each of these pads.

external power input jacks are mounted on the rear apron. The ac fuse is mounted on the power supply PC board.

The small internal speaker is epoxied to the top of the cabinet for want of any other available space. A larger speaker or phones may be plugged into the front panel jack which cuts out the internal speaker.

That should give you the overall basic picture of what the Minicom MK IV is and the rest to follow will take up the circuitry and construction of each of the sections individually.

Tunable I-f Assembly

For purposes of identification this assembly will be called out as PC-1. Fig. 1 is the schematic for this board.

Recent receivers in this series used MOSFET rf amplifiers which often were plagued with problems of oscillation and instability. For this version, I decided to go back to the old MC1550G IC in the rf stage. The receiver pictured here has been working fine and not shown any tendency towards instability whatsoever. The mixer which follows is also an IC and one which I've used since the MK II. The SG3402T is a proprietary product of Silicon General. It provides good conversion gain with very light oscillator loading, thus eliminating the need for buffers. The VFO tank coils on previous Minicoms were wound on stripped down 455 kHz i-f transformers, as were the antenna and mixer transformers in the rf section. I later found that in some cases this tank coil caused excessive drift in the VFO and the scheme was abandoned. Since no harm comes to the rf and mixer circuits, however, this construction is still employed here. The new VFO tank coil consists of a pie-type winding of litz wire on a standard slug-tuned coil form.

Output from the mixer is fed unfiltered to an amplifier stage whose main purpose is to build up the noise spikes to a level the blanker can do a job on. The blanker itself consists of a diode gate using 1N60 diodes and a pulse amplifier fed from an envelope detector which controls the gate. The pulse amplifier is capacity coupled to the output of the first i-f amplifier and the gate is transformer coupled. Output from the gate terminates in the first of 2 dual ceramic filters used for selectivity in the i-f strip. The 1N60 diodes are normally forward biased and do not impede transmission of the i-f signal. When a noise pulse appears at the input to the pulse amplifier, its drain voltage drops towards ground and momentarily reverse biases the gate diodes, preventing transmission of the noise pulse through the gate. The circuit is quite effective for impulse type noise but is of little value against fluorescent lights, power leaks, etc.

Following the blanker is a stage of i-f amplification using a SD304 dual gate MOSFET. These devices by Signetics operate with all positive bias, making AGC requirements simple. These transistors are run with a small fixed positive bias on gate 1 and an AGC controlled positive bias on gate 2. As gate 2 bias approaches zero, gain drops rapidly and can affect changes as great as 40 dB. Output from this stage is

	L3 (molded choke)	Y1 (HC18/U or HC25/U holder)
40m	4.7 uH	11 MHz
20m	2.2 uH	18 MHz
15m	1.5 uH	25 MHz
10m	(same tank circuit as 15m)	

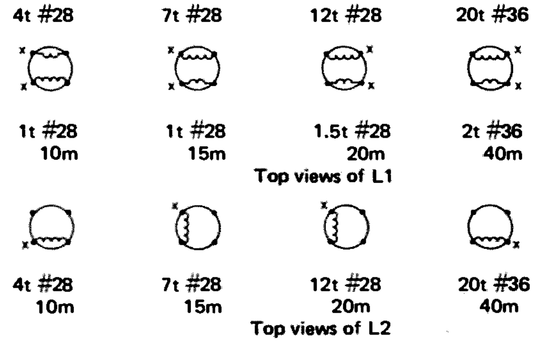

Table 1. All coils wound on Gowanda Series 7 coil forms. Forms are .209" diameter x .625" long with Carbonyl E cores. "X" indicates cold or ground end of winding.

transformer coupled to the second ceramic filter, which completes the circuitry assigned to this board.

Detector and Audio Section

This assembly is PC-2 and the schematic for it is Fig. 2.

A second SG3402T IC is used as detector for both AM and SSB/CW, it being necessary only to disable the BFO for AM reception. The SG3402T has 2 outputs via pins 3 and 8. In this case, pin 3 is used as the main audio source and is fed to the preamp which uses half of a dual op amp. Output from the preamp connects to either the audio gain control or is left open if the CW filter is in use. In order to maintain a fairly constant input to the CW filter, audio from the preamp is fed to a saturating amplifier circuit and from there to the filter. The filter itself consists of 2 identical active bandpass filters joined by a threshold detector.[4] Both sections are tuned simultaneously by a dual 5k pot. A 3 position switch allows the filter to be cut out of the circuit, operated with the threshold detector shorted out for medium selectivity, or with the threshold detector intact for sharp response. It will not always be practical to use the Sharp position, since weak signals or QSB may cause the signal level to fall below the barrier potential of the diodes and cut out altogether. In such cases, the Medium position will still provide a good deal of selectivity. The frequency range covered by the filter is approximately 400 to 1600 Hz.

An LM380N-8 is used in the audio power amplifier stage. This IC is rated at 600 mW output and requires few external components.

The BFO is diode tuned and uses a standard 455 kHz transistor i-f transformer for the tank circuit. Before installing the transformer, the secondary is modified to 4 turns so as to supply proper injection level to the detector. Operating voltage for the oscillator and bias for the tuning diode are zener regulated.

Audio output from the detector is used as the source for generating AGC voltage and is taken from pin 8. The second half of the dual op amp is used to amplify the audio about 30 times before rectification. The resulting positive voltage is stored in an electrolytic capacitor and bled off at a rate determined by the setting of the T/C control. The latter is a front panel control giving the operator a choice of AGC decay time over a continuous range of milliseconds to seconds.

The FET which follows amplifies and inverts the dc voltage appearing across the electrolytic capacitor so that as signal increases, the level at the top of the rf gain control decreases. This is the proper action for control of the SD304, and when I used this transistor in all gain-controlled stages, no further circuitry was needed. Now, however, a reverse effect is required for the MC1550G used in the tuner rf stage. The SD304 operates at full gain when the AGC level is 5 to 6 V. The MC1550G doesn't start to lose again until the AGC starts to rise above this level, making a second inversion necessary. This is accomplished with an additional FET. The rf gain control does the same thing as the AGC when manual control is desired.

It may be worth noting that an early version of the MK IV used separate sources for AGC control. As might be expected, output from the i-f amplifier was used during AM reception in place of the audio source. Since AM is seldom used, this extra circuitry and additional switching were eliminated to save space. Though perhaps not ideal for AM, the audio AGC works well enough to make AM reception practical whenever it is needed.

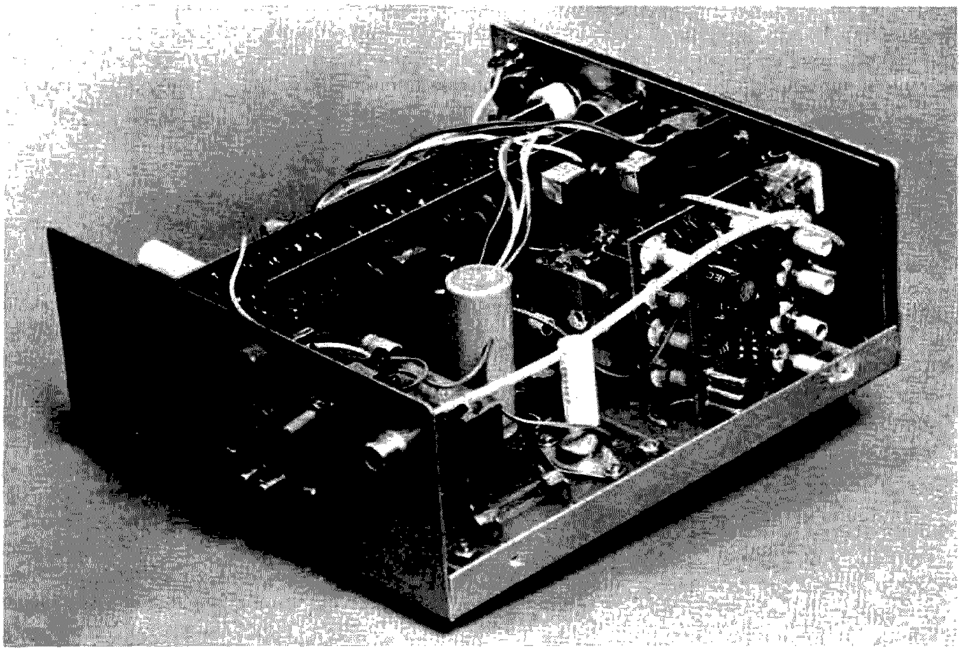
The S-meter amplifier is the final item included in this assembly. Control voltage for this stage is taken directly from the storage capacitor. Trimmer R1 controls meter sensitivity by setting the amount of AGC voltage applied to the meter amplifier. R2 is used to balance the circuit for zero deflection under no-signal conditions.

There are 3 other trimmers on this board intended for various purposes. R3 is the AGC threshold adjustment and sets the point at which AGC starts to affect gain relative to signal strength. R4 is used to set the static AGC level of 5 to 6 volts mentioned above. The last trimmer, R5, is a tracking adjustment for the 2 sections of the dual pot used to tune the audio filter.

The heart of the converter is the Stackpole Series 80 subminiature rotary switch. It is rectangular in shape and measures 13/16" x 9/16". Each section is a totally enclosed module and up to 10 of these decks may be combined in various configurations to make up the desired switching pattern. In the case of our converter, 5 sections of 1 pole, 5 positions are required. All the contacts emerge along one side of the module and are spaced on one-tenth inch centers along both axes. To conform with the design of the converter, 2 sections have their contacts brought out one side of the switch and 3 sections on the opposite side. The 2 PC boards are both 2" square and mount directly to the switch on opposite sides. One board had to be made 2-sided to accommodate all the circuitry, but a single-sided board was sufficient for the other. The double-sided board contains the rf amplifier with its 4 antenna coils and the 3 crystals for the oscillator. The second board houses the mixer with its 4 coils and the remainder of the local oscillator circuitry. Overall thickness is 1-5/8".

Fig. 3 is the schematic for the converter whose circuit consists of a cascode rf stage using a pair of JFETs followed by a dual gate mixer. A second JFET functions as crystal oscillator. The switching is arranged so that the antenna feeds right through on 80 meters.

A 25 MHz crystal is used for coverage of both 15 meters and the low end (28.5 to 29.0 MHz) of 10 meters, thus economizing on both cost and precious space. If coverage of some 500 kHz segment other than those used here is desired, suitable crystals and tank coils may be substituted. Also note that with this design 40, 20, and 15 meters tune backwards.



Internal layout showing vertical mounting of all assemblies except power supply in center foreground.

The 10 meter band will tune normally from low to high with CW rotation of the tuning capacitor since the crystal is on the low side. As built, the converter covers 7.0 to 7.5 MHz, 21.0 to 21.5 MHz, 14.0 to 14.5 MHz, and 28.5 to 29.0 MHz. The tunable i-f covers the 80 meter band from 3.5 to 4.0 MHz.

Power Supply

A simple basic regulator circuit is used in the power supply and requires no particular comment. It is entirely self-contained, including transformer, on a board 2.3" x 3.1". Output is 12 volts at 150 mA. A schematic for the power supply appears in Fig. 4.

That just about covers everything that's in the receiver, so now we can get on with the actual building. I hope you're a real honest-to-goodness do-it-yourselfer and will be making your own boards, too. That's half the fun and not nearly as difficult as so many readers seem to think, judging from the mail I get.

The only real problem area regarding fabrication of the printed circuits used in the MK IV is the double-sided board used in the converter. I generally cut out a cardboard frame for all my boards so that the board fits snugly in the cutout and can't move during handling. The film is cut slightly larger than the opening and once lined up is fastened with tape around the edge. To expose 2-sided boards, I line up the second film on the backside and fasten only one edge with tape. This film is then merely hinged and can be lifted to insert the 2-sided board. Each side is then exposed in turn and the board processed as usual.

Assembling PC-1

All the holes will have to be drilled before any components can be mounted, and it would be well to go ahead and drill all the boards at one time. I generally don't bother with anything smaller than a #65 drill, but you may if you wish a real snug fit on semiconductors or other components with fine leads. Most holes can be drilled with either a #60 or #65 drill. Use a #50 drill for the 2 mounting lugs on the 455 kHz i-f cans and a #30 drill for the 2 screws holding the 3-gang variable capacitor. The #30 drill can also be used for the 2 power transformer mounting lugs and the tuning slug access holes on the single-sided converter board. The power supply regulator transistor can be mounted with either #2 or #4 screws, so drill the 2 holes to suit. The 4 corner mounting holes on this board can be drilled for #4 screws. About the only other odd holes are those for the vertical trimmer resistors on PC-2 which require a #54 drill.

As with assembly of all the boards making up this project, a few basic rules to follow will make the job easier. In line with this, I generally mount the shallowest components first since the board is usually turned on its back during soldering and direct contact of the component with the top of the bench prevents it from falling out. This means all resistors and diodes go in first. The smallest discs, silver micas, semiconductors, and ICs would follow, with the larger discs, electrolytics and transformers going last. In most cases, you can tell what order to follow by laying out all the components in proper sequence by height. Try to keep heating of germanium diodes to a minimum since they are the most temperature sensitive parts you'll be installing. A small iron is essential, but not one with inadequate heating capacity. The rest of the DOs and DON'Ts I'll skip, since you've heard them all before and if you are tackling this project, you must be a big boy now.

The rf transformers and VFO tank coil will have to be wound before proceeding with the assembly operation. All the winding information is contained in Table 2. T1 and T2 are wound on stripped down 455 kHz transistor i-f transformers of the 3/8" square variety. Wire salvaged from the transformers is used to wind the new coils. If you read reference 2, you'll get a few tips on how to go about this operation.

Winding T3 is a little more of a problem if you don't have a coil winding machine. I use one of those that's been advertised in many of the mail order catalogs since the year 1 and sold under the name of MoReCo the last I looked. When I bought mine,

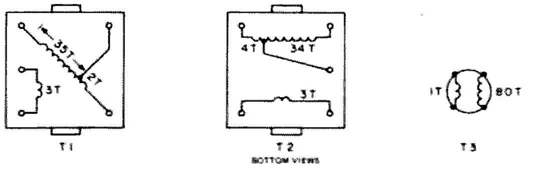


Table 2. T1 and T2 are wound on stripped 455 kHz transistor i-f transformers using salvaged wire. T3 is pie-wound with 7/44 litz wire on a Gowanda Series 7 coil form with Carbonyl E (red) core. The 1 turn link is wound over the top of the pie.

it was a Morris coil winder. A ¼" cam is used and the winding located as close to the bottom of the form as practical. Impregnate the winding with a generous dose of coil wax when done. Use standard 455 kHz i-f transformers for T4 and T5.

Don't forget that unlike other ICs in T0-5 cans, the MC1550G has pin 1 located adjacent to the tab and not pin 10. Also, before installing the SG3402T you'll have to cut off pin 6 since there is no hole for this lead in the board.

The 20 pF padding capacitors across the rf and mixer gangs of the tuning capacitor are mounted right on the capacitor before installation. One end of each padder is soldered to the frame and the other end to the stator connection on each of the first 2 gangs. Before mounting the variable capacitor, you should grind the shaft to desired length and also clip the 3 stator solder lugs to 1/8".

The drain resistor for the noise blanker pulse amplifier is selected during test and a 1k resistor should be temporarily installed. The 100 Ohm source resistor is mounted externally. See Fig. 9.

The SFD-455D filters have small circles molded into the top of the case at one end. Mount these parts with the circle towards the 20 pF coupling capacitor associated with each filter.

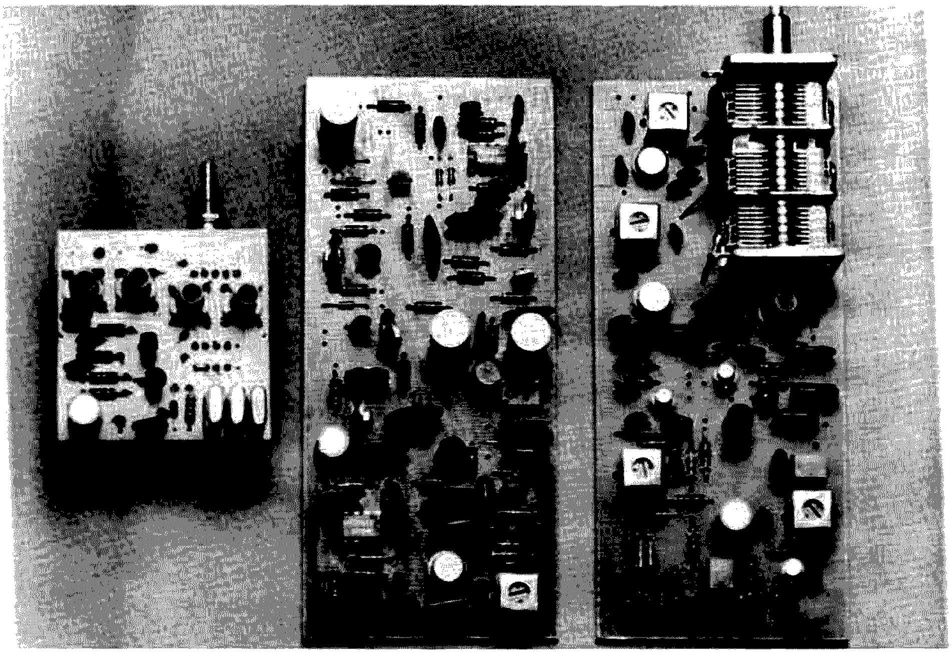
The 3-gang tuning capacitor will be the last item installed. Use #4-40 screws with internal tooth lock washers under the head and insert from the copper side of the board. Use 2 flat washers between the board and the frame of the variable capacitor at each screw in order to clear the rivets and prevent distortion of the board when the screws are tightened. Long pigtails cut from resistors during assembly can be used to connect each gang to its respective pad. These leads should be soldered to the capacitor stator lugs before mounting, since little room is left after mounting. The free end of each lead can be guided into the proper hole as the capacitor is mated with the board.

PC-1 and PC-2 both have several pads available for the +12 supply and are so marked right on the board. You will also find a number of empty holes around the copper border which are there for ground returns if needed. The remaining pads with empty holes amid the copper circuitry are for connections to external controls or to other boards and can be left alone for the present.

Assembling PC-2

Proceed with this board just as with PC-1. There are no coils to wind, but there is a modification to perform on the BFO transformer (T1) before it can be installed. Using a standard i-f transformer, remove the assembly from the can and break off the secondary leads right at the point where they enter the bobbin. A pair of fine tweezers is ideal for this operation. Unsolder the remaining wire from each of the pins and clean off any excess solder. Using a piece of salvaged wire from the rf transformers, wind a new secondary of 4 turns right over the existing windings and solder the ends to the secondary pins.

Clip pin 6 on the SG3402T as before and you are ready to start mounting parts. Assembly is quite straightforward and when the board is complete, set it aside with PC-1 until everything is ready for testing.



Top view of converter, PC-2 and PC-1 fully assembled.

Assembling the Converter

I've taken a lot of liberties with construction of the converter and you may not agree with some of the techniques employed, but it did allow me to squeeze 10 pounds into a 5 pound bag. If anyone comes up with any good ideas on improving this beast without increasing the size, I'd like to hear from you.

As I mentioned earlier, one of the 2 converter boards is 2-sided. One side contains all the circuitry while the other is a ground plane. All the components for this board are mounted on the wiring side, which becomes the top of the converter. This means that all leads will have to be soldered to their pads right at the point of entry except for those connecting to ground on the other side. You can tell which leads get grounded by whether or not the copper has been etched from around the hole on the backside.

There are 4 locations where it is impossible to solder the leads because the pads are covered by the component when it is inserted into the board. These 4 points include one end of each crystal and the positive terminal of the electrolytic filter capacitor. Since I don't have plating-through capability in my rather simple printed circuit facility, I solved this problem by inserting a tiny eyelet through the top of the board and soldering the head to the pad. The component lead is then soldered to the barrel of the eyelet on the other side.

The coils are wound as shown in Table 1. Make certain you get the right orientation when inserting the coil into the board. The crystals may be in either HC18/U or HC25/U holders to fit the layout. I personally prefer the latter since the pins seem to take solder better than the wire leads.

The bottom board is assembled in the normal manner, with components

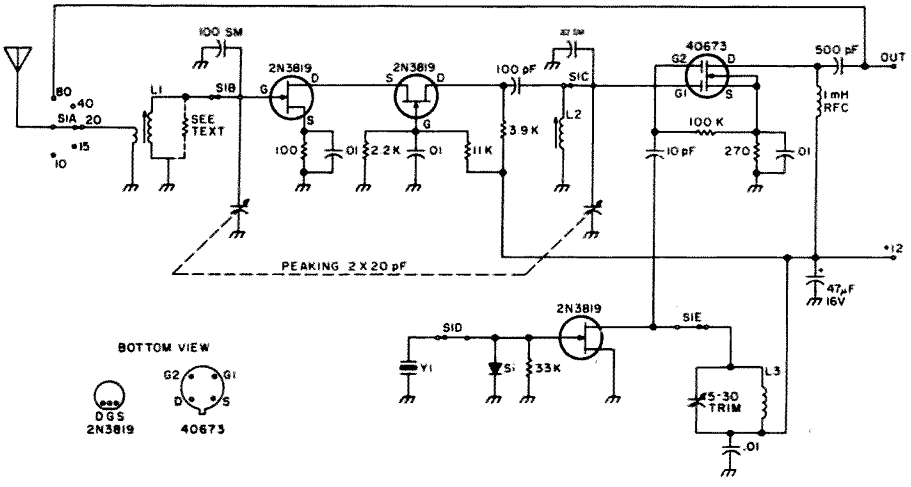


Fig. 3. Converter schematic. Coil winding information appears in Table 1. All resistors are ¼ Watt, 5%. All decimal value capacitors are low voltage discs with values in uF. The capacitors marked SM (silver mica) are in pF.

mounted on the clear side. The ground plane for this board, as with all previous sections, is the copper border around the outside edge. Eventually all printed circuit grounds will be made common with each other and the metal cabinet.

When mounting the 3 subminiature trimmer capacitors used to tune the oscillator tank circuits, try and connect the rotor side to ground. If you look at the top of the trimmer, you'll see a tiny slit at one end where the lug comes up and connects to the stator plate. This end should go to the choke (tank coil) and the other end to ground. The chokes used for the tank coils are mounted vertically in hairpin fashion, with the bottom of each choke seated in the hole closest to the middle of the board. The top leads are bent a full 180° and inserted into the proper mating hole.

There are 5 jumpers and 1 component wired between the 2 boards when the sandwich is complete. The component is the 500 pF disc capacitor connected between the mixer drain and converter output. Cut one end to about ½" lead length and solder this end to its pad on the bottom (single-sided) board. Next you can mount the bandswitch to this board, being careful not to damage any of the pins. Once the 2 switch decks are fully seated, solder all the connections. Now mate the top board with the 3 remaining switch decks topside. Insert the free end of the 500 pF disc into its pad and clip off any excess lead after soldering. As soon as everything is seated properly and the 2 boards appear to be parallel, solder all switch connections.

The remaining jumpers are mostly straight through and here again you can use pigtail clippings. Use sleeving if you wish to insulate these leads, although it is not necessary. There are 2 jumpers joining the ground planes on each board, and you'll find these holes halfway up each side right at the edge of the board. The next 2 jumpers are at the rear of the assembly. One of these joins the 12 volt bus on each board. Use the innermost of the 2 12 volt pads on the top board and the pad between the 40 and 20 meter coils directly below. There is a slight offset to this pair of holes. The other pair joins the 100 pF coupling capacitor from the rf amplifier to the mixer gate. These 2 line up exactly and fall between the 20 and 15 meter coils below. The final jumper is up front and joins the gate of the crystal oscillator transistor with the switch deck that selects crystals. There is about ½" of offset between these 2 holes. On the top board, use the second hole from the right, and the hole directly in front of the oscillator transistor on the bottom board.

Putting it All Together

The receiver was assembled on a sub-base and sub-panel constructed of regular G10 printed circuit material. The panel and base were cut to fit snugly inside the cabinet and were joined by soldering to form an "L" shaped sub-chassis. The pots, switches, S-meter, and phone jack were all fastened directly to the sub-panel. All assemblies but the power supply were mounted vertically to the sub-base with PC-1 in the center. Short lengths of brass angle were soldered along the bottom edge of PC-1 and PC-2 and then drilled to take #4 screws which fastened the boards to the bottom of the cabinet. PC-1 was mounted with the tuning capacitor at the bottom and PC-2 with the BFO transformer up front and facing the outside. This puts these 2 assemblies back to back. From front to rear, PC-1 is positioned so that the end of the large outer shaft on the tuning capacitor is flush with the outside panel. PC-2 has to be positioned farther back in order to clear the front panel controls.

The converter is mounted by fastening the bandswitch to the sub-panel with the switch towards the bottom. A jumper is soldered from the ground plane on each board to the sub-base since there is no other means by which the converter gets grounded. A very small 2-gang variable capacitor from an FM transistor radio was found to fit between the converter boards and is used to peak the rf circuits.

The power supply was mounted parallel to the base behind the converter and is partly visible in the photo. Small standoffs are used in each corner to keep the printed wiring from shorting against the base.

The holes in the front panel were made just large enough for the 1/8" shafts to clear. Since very small knobs must be used to accommodate all the controls in the limited space, a large hole would be unsightly if the knob couldn't cover it. The knobs I used are only 5/16" in diameter and are not really knobs, but were made by someone unknown from unknown material whose origin is lost in antiquity. I had only 6 when I built the MK IV, so I had to keep the number of controls to that number. The remaining controls will take real knobs and you can select those that suit your fancy.

The 2 toggle switches in the bottom row were fastened to the sub-panel but allowed to extend all the way through the front panel where a second nut was used to hold everything together. The phone jack barrel was too short to take a nut so I epoxied a flat washer around the opening to dress it up.

The S-meter is one of those very common subminiature edgewise types with nothing but a 3-color scale and no calibration. Movement sensitivity is 500 uA. A small strip of tape and

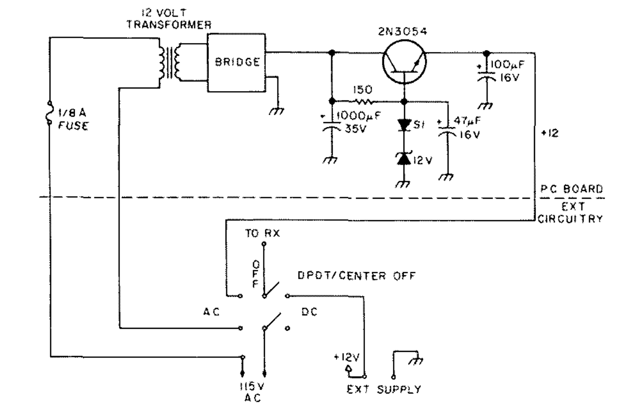

Fig. 4. Ac power supply schematic. The external circuitry was mounted on the rear panel of the cabinet. The bridge rectifier is a TO-5 size molded unit of at least 50 volt rating. The power transformer is a surplus item and is mounted right on the board.

some transfer lettering transformed it into a neat little S-meter. There was only enough room for 3, 5, 9, and a + sign to indicate signals over S9.

The remaining panel hardware consists of a phono jack for antenna input, a DPDT power switch with center-off position, a pair of banana jacks for external power input, and a connector for the ac power cord. All of these mount on the rear panel. If you wish to have reverse polarity protection when operating from external sources, connect a suitable diode between the +12 jack and the power switch in place of a piece of wire.

A full size panel layout is shown in Fig. 10 for use with the Radio Shack #270-254 cabinet. If you go with this setup you'll have to come up with some small knobs. Also, if you find a suitable variable capacitor for the peaking control, you'll have to make a shaft for it, as these little solid dielectric variables don't come with a shaft. This component is not vital, however, and can be left out. If it is, delete the title from the artwork.

The dial portion of the panel artwork has 2 blank scales. One of these can be calibrated to read from .5 to 1.0 in the clockwise direction and the other from 0 to .5 in the reverse direction. When using the 3.5 or 28.5 MHz bands, you will use the first scale, and when switched to 7.0, 14.0 or 21.0 MHz, you use the other scale. As you can see, I calibrated every 100 kHz, but some intermediate steps could be included. Only one set of calibration marks is needed since the scales are exact reciprocals.

Everything You Wanted To Know About Parts

At this point you may be thinking it's a nice project but not worth risking one's sanity trying to find all the parts. I must admit that you would have a lot of trouble obtaining some of the items, so I've been slowly amassing a shoe box full of spares to help out. If you write for a price list or anything else, please enclose an SASE or you won't get a reply.

Some parts can be substituted and the obvious ones we'll skip. The dual JFET S-meter amplifier is one possibility. I had an E421 on hand but some unmarked types in my junk box worked as well. I specified diodes as either germanium or silicon because I found no noticeable difference in performance with any particular type. Some very worthwhile bargains in first line diodes can be found in many ads in *73*, so take advantage of them. The 1N60 did work slightly better in the blanker gate so was the one diode I spelled out. The 1N60 is a germanium type if you wish to experiment. For the silicon units there are plenty of 1N914s and 1N4148s around at bargain prices.

There are only a couple of bipolar transistors in the entire receiver and these are not critical. Just don't try to use a PNP for an NPN. The

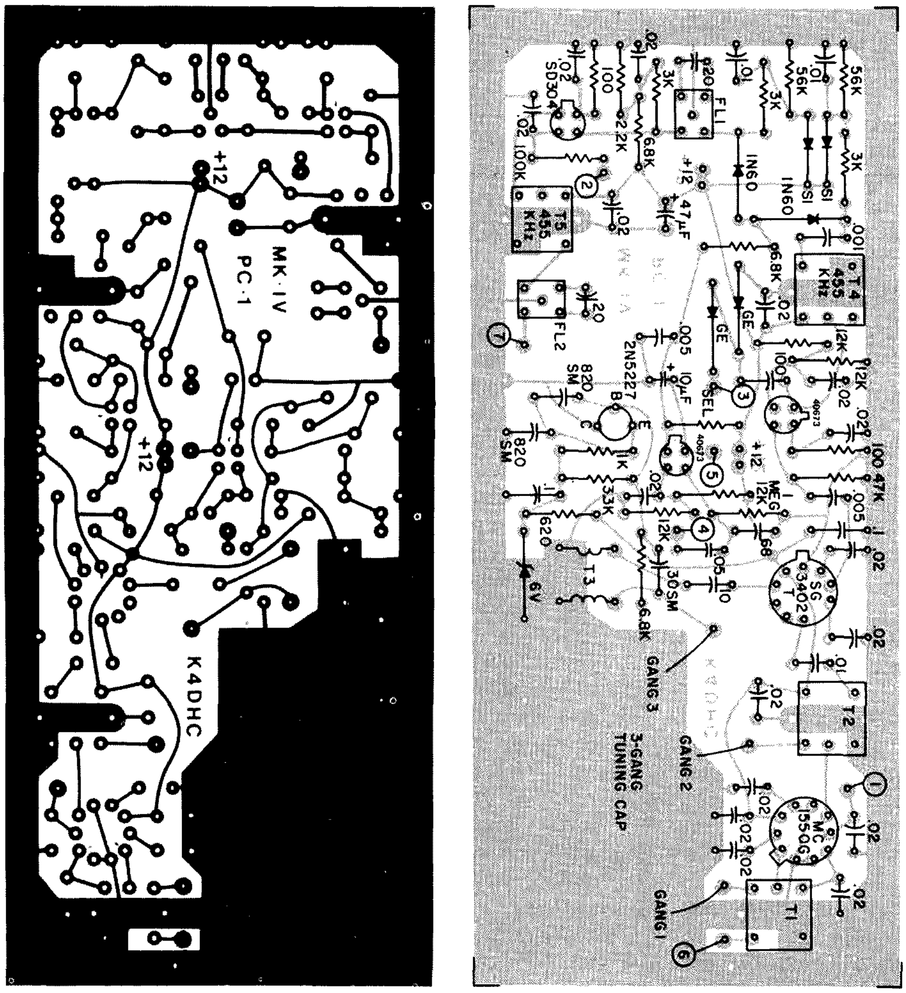

Fig. 5. Assembly PC-1 board and component layout.

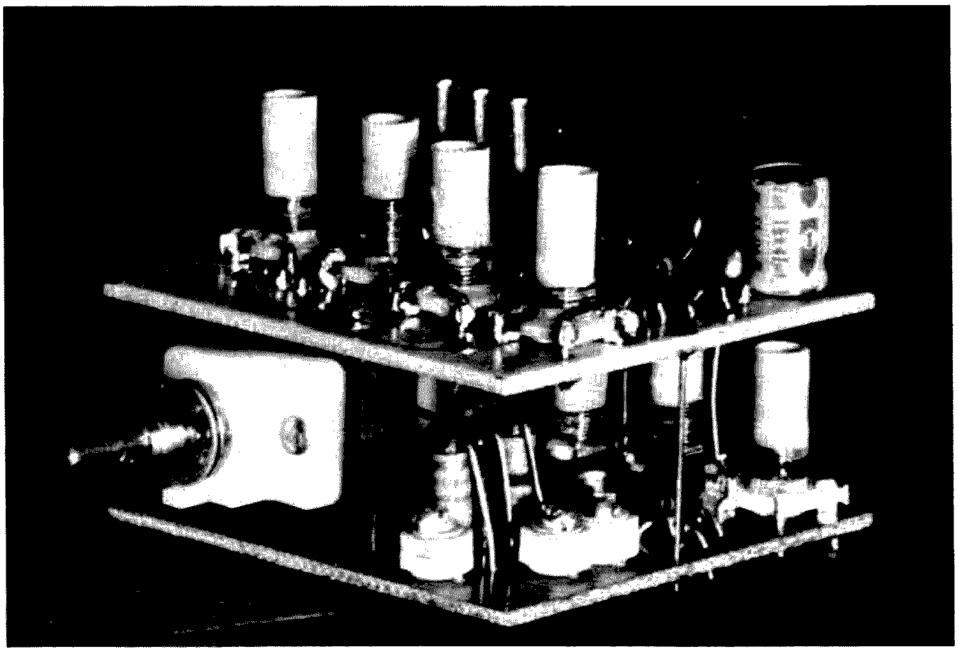

This view of the converter shows additional details of the sandwich construction.

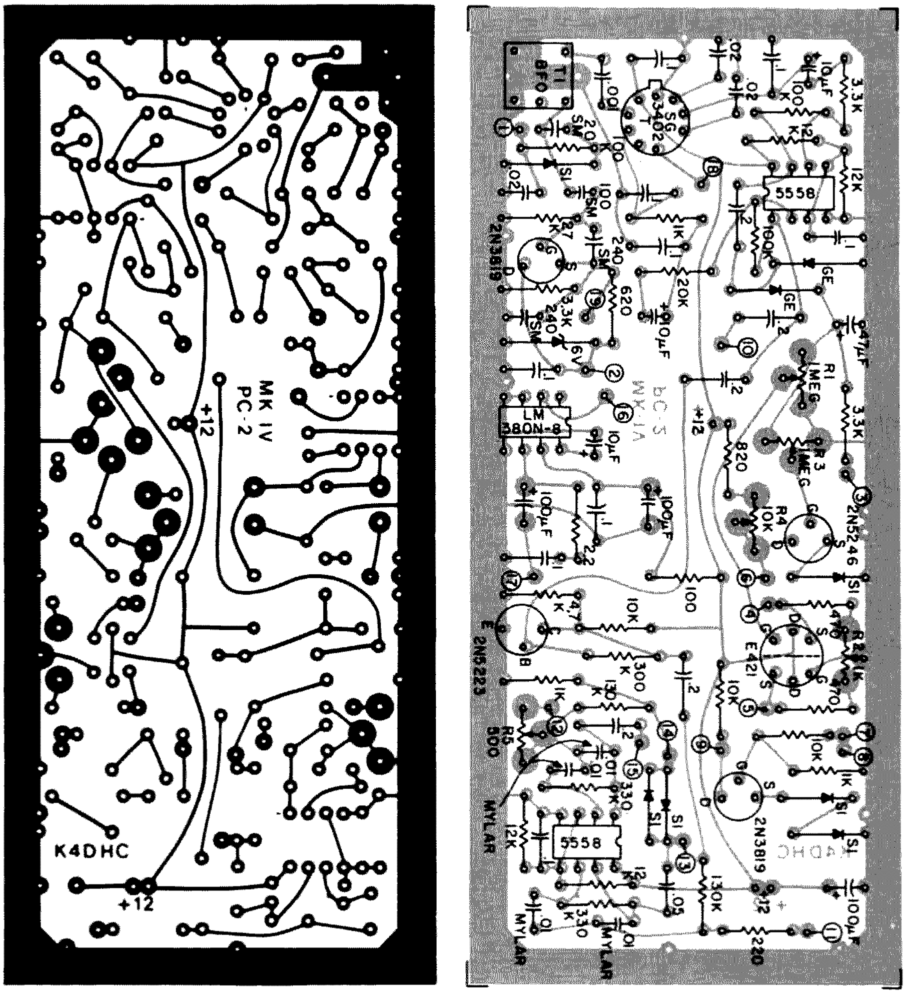

Fig. 6. Assembly PC-2 board and component layout.

40673 dual gate MOSFET has possibilities, such as the 40841, but don't try to substitute for the SD304 which is best left alone.

The tuning capacitor is the same one I've used for all the Minicom receivers except the MK III. It is equivalent to the old J. W. Miller #1460 but has a built-in 7:1 reduction. A pointer will have to be made for it from a piece of clear plastic. You can scratch a hairline in the plastic with a sharp instrument and fill it in with a red ballpoint pen. A nylon screw insulator with a ¼" hole makes a good hub for the pointer and will slip right over the outer shaft of the variable capacitor. If it's a little loose, a single layer of masking tape on the shaft will snug it up.

As I mentioned before, knobs are the big problem, and if any reader has a solution or the facilities to produce some 5/16" knobs for 1/8" shafts, please let me know.

The controls themselves will have to be the ½" or 5/8" diameter types to fit the space available. There are a lot of these around, so keep your eyes peeled when you read the ads. A dual 5k pot in this category is another story and it's not likely you'll find one. By the time this is published, I hope to have some of the little Clarostat ½" square Series 388 pots in a dual 5k version in my shoe box. There is one in the receiver pictured but it is not visible.

The 3 position toggle switch I used for the CW filter mode selector is an Alco MST 205PA. This switch makes some circuits in the center position, so don't try to use a regular DPDT with a center-off position.

Before concluding this section, I should point out that there is no reason why the receiver couldn't be made slightly larger and some of the problems thereby cured. The receiver as it stands is not the most convenient instrument to use from the human engineering standpoint. I cer-

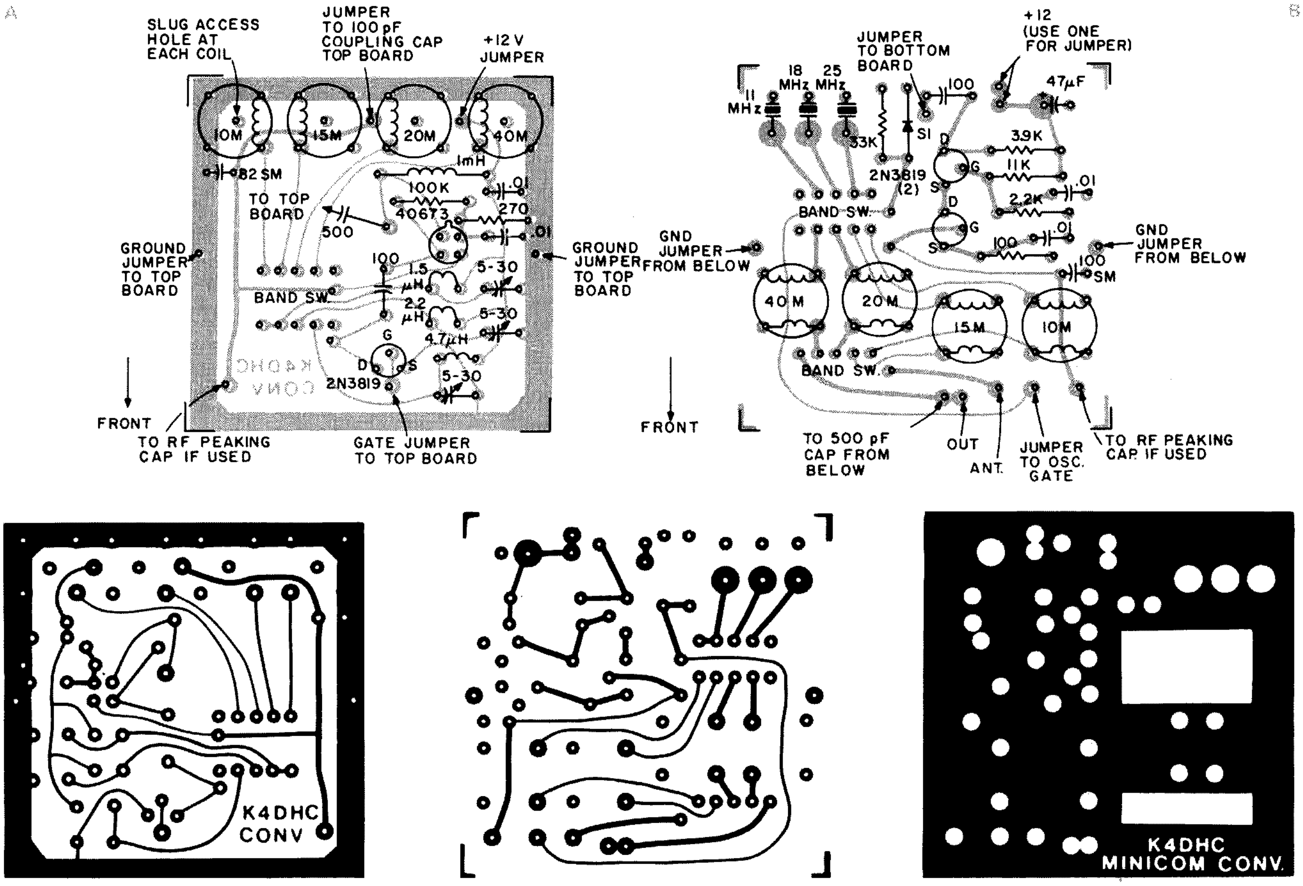

Fig. 7. Converter bottom board PC and component layout (a) and top board (b). Jumpers are explained in the text.

tainly wouldn't recommend it as a station receiver unless you had very small hands and very thin fingers. On a short term basis, however, such as business trips, vacations, or during an emergency, its many extra features would make it acceptable.

Getting It To Work

The best way to tackle initial alignment is to get the 80m section working first. This means that PC-1 and PC-2 will have to be wired up with their controls and interconnections. I've found that the easiest way is to just lay it out on the bench with nothing actually mounted. The leads going to the controls can be cut to about the right length for cabinet mounting and should require minimal trimming later. Besides the controls and switches, you'll need the following wiring:

1. A lead to pad #6 on PC-1 for the antenna or input.

2. A lead from pad #1 on PC-1 to pad #9 on PC-2.

3. A lead from pad #2 on PC-1 to pad #8 on PC-2.

4. A lead from pad #7 on PC-1 to pad #18 on PC-2.

5. A lead from +12 on PC-1 to +12 on PC-2.

6. A lead from +12 on PC-1 to the power supply.

7. A lead from pad #17 on PC-2 to the speaker. Later the lead will go to the phone jack.

Pad #4 on PC-2 is the positive connection for the S-meter if you wish to connect it up at this time. The initial settings prior to firing up are:

1. Set all trimmer resistors on PC-2 to mid position.
2. Set tuning capacitor to full mesh and turn the 2 compression trimmers up snug but not tight.
3. Switch blanker OFF, rf gain to maximum, CW filter OFF, detector to SSB/CW, BFO at mid position, and audio gain to suit.
4. Tie all grounds together with short clip leads.
5. Fire up.

If no smoke is seen, the first thing to do is get the BFO on frequency. If you slowly run the slug in the BFO transformer out towards the top, you should hear some noise when you hit 455 kHz. Adjust the slug for zero beat, which will be the dead zone between noise peaks as you pass through the i-f frequency. The BFO control should then vary the BFO frequency as indicated by noise buildup on either side of zero. The action won't be linear, but don't worry about it.

The next thing is to get the VFO running at about 3 MHz. I use a scope, but if you don't have one, use a counter, a general coverage receiver, or brute force. This latter means feeding a hefty signal in at 3.5 MHz and adjusting the slug in the VFO tank until a signal is heard. Once the VFO has been set by one of these means for the low end of the band, feed in a barely detectable signal at 3.5 MHz and peak T1 and T2 on PC-1. At this time you know the receiver is working and the AGC should be set.

Leave the rf gain at maximum and remove the signal generator. Turn R3 all the way towards ground. With a

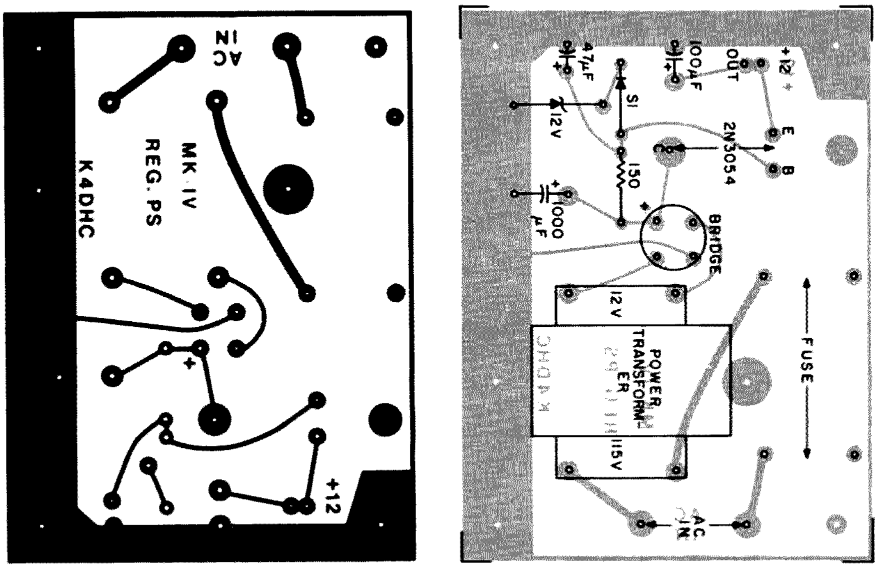

Fig. 8. Power supply PC board and component layout.

scope or high impedance meter connected to the top end of the rf gain control, adjust R4 till a reading of 5 volts dc or slightly less is indicated. Advance R3 about one third of its total travel and you should be in business. R3 sets the AGC threshold and can be advanced or retarded to suit your idea of how tight you'd like the action to be.

Now you can go back to aligning the front end. T1 and T2 should be peaked at the low end and the 2 compression trimmers used to peak the high end at 4.0 MHz. Several trips up and back will be required before everything tracks properly. A final adjustment of the VFO frequency should also be made to center up the band within the full swing of the tuning capacitor.

The 2 i-f transformers on PC-1 tune rather broadly, but you can run the cores through their travel once to get the best setting.

The remaining trimmers on PC-2 can be adjusted next. Turn the rf gain to minimum and set R2 for zero S-meter reading. Later on when you're listening to some strong signals, you can adjust the meter sensitivity with R1. R5 is most easily adjusted by using a steady signal from a signal generator. Adjust for a note falling just inside the high end of the CW filter tuning range and with the filter in circuit, peak the response with the dual tuning pot and then repeak with R5. Repeat a few times to make sure you're as close as possible.

The last thing to check out is the voltage level at the drain of the pulse amplifier in the noise blanker circuit. With the blanker ON, the level should be about 5 volts for best action. The 1k temporary resistor may or may not be the right value. Lowering the resistance raises the voltage and vice versa. When you've arrived at the proper value you can make a permanent installation.

Now you're ready to tie in the converter. Switch the input lead to PC-1 over to the converter output, and the antenna to the converter input. Run a lead from the +12 pad on top of the converter to a +12 pad on PC-1. Clip the converter ground to the rest of the grounds.

With the bandswitch in the 80m position, make sure everything is still working. If so, the next step is to get all the crystal oscillator circuits started. I usually use a scope to observe the crystal oscillator output, but a hit and miss technique will work, too. If a band is dead at a time when there should be signals present, turn the trimmer for that oscillator tank a bit at a time until you start hearing signals. For dead bands you'll have to rely on a signal generator. L1 and L2 for each band can be stagger-tuned for best overall response across a given band, or a small 2-gang variable can be used for continuous peaking. There is a pad on each converter board for connecting to the capacitor. Don't forget to ground the common rotor connection.

There is a possibility of oscillation occurring in the rf amplifier stage of the converter. The receiver shown in the photos had this problem on 40m and required the addition of a 12k resistor across the secondary of L1 on that band. The resistor was soldered directly to the pins on the base of the coil form. If similar problems come up in your receiver, apply the same remedy using the largest value of resistor that cures the trouble. Make no evaluation, however, until every-

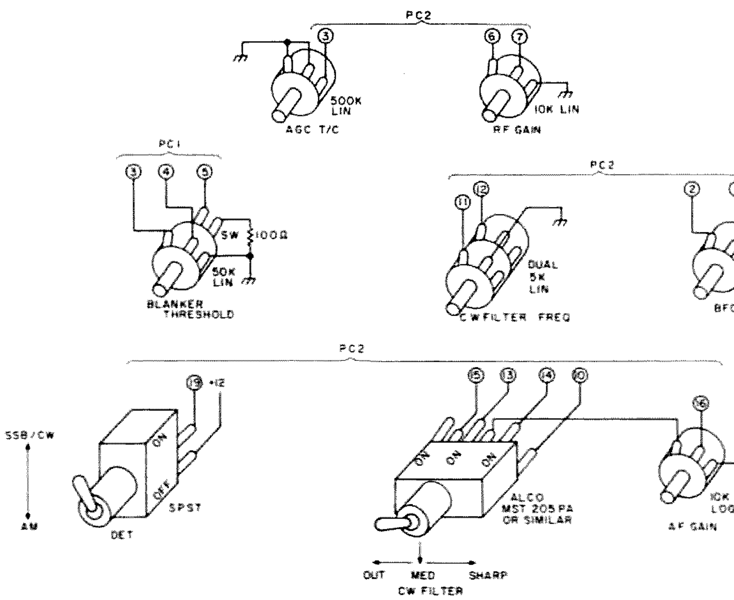

Fig. 9. Pictorial wiring diagram of front panel controls.

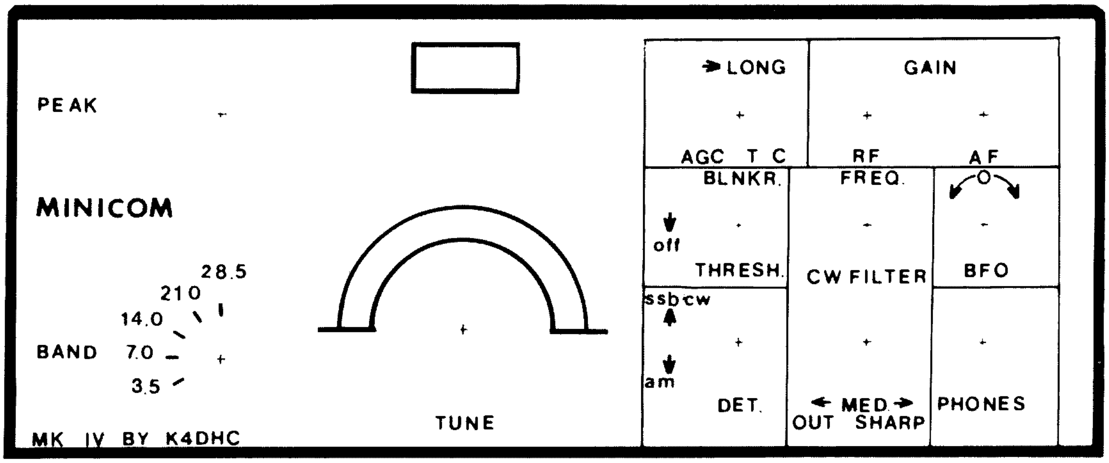

Fig. 10. Front panel layout for the Radio Shack cabinet.

thing is mounted and wired in its final form.

Conclusion

The MK IV was fun to build and operate. The biggest improvement to me was the CW filter. It really peaks up a signal buried in a pile of 2 or 3 others. Incidentally, the 4 mylar capacitors used in this circuit should be matched as closely as possible so that the 2 sections track fairly well.

The noise blanker has also proven to be a big blessing at times. On many occasions it has made unreadable signals perfect copy.

One final point before concluding might be worth mentioning. As I noted earlier, the BFO tuning is not linear due to diode characteristics, so you may want to shift the zero beat point down towards the low resistance end of the pot. The knob can be offset so that the pointer is straight up at zero beat.

Using a generator with crystal checkpoints or some other accurate signal source, mark the calibration points on the dial scale and fill in the numbers with transfer lettering. Voila! It is done. ■

Those Illegal CB Channels

-- and the tens of thousands using them

Yes, believe it or not, there *are* some significant differences between the CB sidebanders and the AMers. Such as local on-the-air conduct. On CB AM it is common to hear something like: "Howaboutcha, Ratchet-jaw? We're a-lookin' fer that Ratchet-jaw, one more time!" The CB sidebanders usually talk in ham-type monologues. During round table (net) discussions, the monologing per person is shorter. But not always! Sound familiar? They talk about technical radio subjects, if not about their own rigs. Sound familiar? When the skip is in, a lot of them "let their hair down" and get a bit excited, and their conduct deteriorates, depending upon the individual. Sort of like our weekend contests!

Fancy handles such as "Jailbird," "Sneaky-Snake," and "Buckeye-Badboy" are not condoned. Any newcomers to sideband who bring fancy handles along with them are soon told about it, either politely — or in no uncertain terms! The sidebanders give their first names or nicknames, such as "John," "Mike," "Carol," and "Dave." There is also a tendency to refrain from excessive tens-code use. Personally, "10-4" and "Roger" sound no more weird than our use of "fine business."

Some of our "ham codes" are used the same way, some differently. They use QSO, QTH, and XYL, for example, verbally the same. However, QRX and QRT are used together: "We'll pass along our 73 to you fellows; we're going to QRX and QRT." Yes, the sidebanders usually "73" instead of "seventy-thirds" or "Threes to ya, Guy!"

The term "CQ" isn't generally used, except a little by a few during skip conditions. Those who use it, use it as we do or some use it in place of the term "break," to catch the attention of skip QSOs already in progress. The latter does sound weird from a ham's point of view. Try to imagine suddenly hearing "CQ-CQ-CQ" from a third party in between transmissions!

Illegalities

Yes, CQing in any matter on the Citizens Band is an FCC no-no. So is working skip. Not to mention general "ragchewing." That's just the beginning!

Ever hear of a Siltronix 1011? Well, for about 650 bucks, this transceiver (that bears a remarkable likeness to Swan's* rigs) will vfo you, not only on all legal 23 class D channels, but also in between, below and well above them! And it will do all this with 100 to 150 Watts output, depending on how hard the finals are blasted! Not bad, 'eh?

Do these rigs sound familiar: Kenwood TS-520, Heath HW-101, Tempo One, Drake's T4X and TR4, and Yaesu FT-101? All of these are very popular with the CB sidebanders. Often these rigs are featured as first prizes at CB gatherings, such as jamborees! These rigs are easily modified to cover eleven meters (the ones without 11 meter bandswitch position). The "10 A" crystal, or its equivalent, is replaced with one suitable to tune "all around" the CB channels.

Maybe we hams are missing out on something here. Do we need more elbow room on 20 phone? Is "75" getting a bit too crowded now, with the foreign broadcasters moving in? Forty meters? And, just think, we can all use that new proposed 10 MHz band *right now!!!* OK fellows — I was only kidding. Besides, it would only mess up our QSL system, because we would have to resort to phony callsigns (usually assigned by a regional club) and central P.O. boxes.

Many CB sidebanders start out with regulation FCC, DOC type accepted radios. However, the "urge-to-slide (vfo)" becomes irresistable. Perhaps the chief reason is to escape from the AM crowd. Channel 16 is the unofficial "sideband-only" slot, but things get kind of crowded here, and the other twenty-two channels in the metropolitan areas are smothered with AMers. Often "16" gets AMed also. So where do they go? And, how do they do it?

Well, one way is those ham or equivalent type rigs I mentioned earlier. However, using existing gear is sometimes more expedient. The owners of older Hy-Gain CB sets merely purchase the accessory, type-accepted, *receiving* vfo, and plug it into the vfo socket on the rear panel. Then, by snipping "that famous yellow wire" inside the vfo, a relay is disabled and your set can slide around from a little below channel one clear up to 27.430 MHz, on both receive and transmit! See Fig. 1. Many "friendly dealers" would kindly snip that wire for you. Other brands of CB sets that use a 38 MHz output synthesizer are easily adapted to the Hy-Gain vfo. I quote from part of Hy-Gain's vfo ad: ". . . and tune in ALL the action!"

Another way to "tune in all the action" is to install one of the other commercial vfos made by such companies as Siltronix (remember them?) and PAL. They have outputs comparable to one of the crystal oscillators in the synthesizer. All you have to do is pull out one of the crystals and run in the vfo line. The AMers do all of this vfo stuff also, but the sidebanders seem to do as much or more of it, percentagewise.

A popular method is to slightly modify one of the synthesizer oscillators by installing a slug-tuned coil, such as a Miller 4204 in series with the crystal switch and transistor base lead. Tuning the slug will easily get you 10 kHz lower in channel frequency. 27.145 is very popular on sideband. See Fig. 1.

Some Surprises

Would you believe that the vast majority of all those ham rigs I mentioned are *not* illegally used on our own bands?

---

*I am *not* implying that Swan®, of Swan Electronics, Oceanside, California, is producing illegally-used, non type-accepted CB rigs, being marketed under a different name. *(Siltronix and Swan are both part of Cubic Corp. — Ed. note)*

Most of the CB operators have only an eleven meter beam. (Many of these are 60 to 100 feet high! Legal height for beam-type antennas is 20 feet, and 60 feet for omnidirectional.)

Quite a few CB sidebanders: A) are considering, B) are studying, or C) have taken the amateur exams. This is almost nil with the AMers.

You may find this hard to believe, but it seems that those who become hams will operate legally in the amateur bands. I guess our own peer group won't put up with too much illegal operation.

It's interesting to note that many CB AMers who have listened to two meter FM liked it. However, many CB sidebanders didn't care for it because (quote), "It sounded a little like AM CB!" *Darn* little, I might add!

More Surprises

There are a lot of licensed amateur radio operators using CB sideband. Many use it as personal communications to "home base" and such, complete with FCC callsigns and legal rigs. A few find it fun to "join the crowd" – if you know what I mean! Hm-m-m. Did "2" or "75" get boring?

CB sideband has many regional and state-wide clubs. Their original intent was and for the most part still is (quote), "To keep (CB) sideband from becoming another mess like (CB) AM!" It's too bad that most of them didn't also try to uphold entirely legal operation in terms of using FCC callsigns, unmodified type-accepted radios, and limited ragchewing, because I believe that as unified groups they had the potential power to speed up the pending extra "sideband-only" channels legislation, etc. As it now stands, I think they would only get the cold-shoulder treatment, due to the illegal operations by their members.

... And More Opinions

From my own observations and very rough headcount, I will venture to say that less than one percent of the AM CBers use or have possession of illegal, high power gear. The CB sidebanders, however, I suspect are up to 40 percent with high power equipment, mostly from base stations.

While looking at the ham gear ads (by *dealers*, not the manufacturers) in the Citizens Band publications and club newsletters, and listening to all of those same rigs in use "all over" eleven meters, I get the distinct impression that we hams comprise only about 50 percent of total amateur radio type gear sales here in North America!

As it stands, I believe that there is absolutely no need for a code-free Communicator Class amateur radio license. Because it's already here on eleven meters – clear up to 28 MHz! In fact, it's here in two stages: 1) Basic Communicator, starting with AM CB, and essentially cheaper radios; 2) Advanced Communicator, or sideband CB, for those who get tired of infantile type of operations, and can afford the higher priced gear. As I stated earlier, it's mostly the sideband CBers who move up to an amateur radio license. ■

Leading Zero Suppression

W. R. Kappele W6AVL
3030 Oceanside Blvd. #7
Oceanside CA 92054

From the articles on counter construction I have seen, it appears that a feature of the 7446, 7447 and 7448 decoders has been overlooked.

These little gems, along with their uncanny ability to make numbers out of pulses, have the added capacity to automatically suppress leading zeros.

Pin 5 on one of these items, when grounded, suppresses the zero. Pin 4, normally high, becomes low when the zero is present and suppressed. Therefore, in order to suppress all leading zeros, one grounds pin 5 on the highest decade, connects pin 4 to pin 5 of the next decade and so on, leaving the last decade open.

Now, when a zero is presented to the highest decade, it is blanked. Pin 4 goes low, arming the second highest decade, whose pin 5 goes blank when a zero is presented there.

When any number but zero is presented on any decade, the zero suppression on all lower decades is automatically lifted. Since about the only thing we are allowed to suppress any more is zeros, let's get up to date and do it. ■

Social Events

GRAND RAPIDS MI
APR 2

The Third Annual Swap and Shop will be held at the Northeast Jr. High School, 1400 Fuller Ave., N.E., Grand Rapids, Michigan, on Saturday, April 2 from 9 am to 5 pm in the cafeteria. Featured will be: CBs, monitors, ham equipment and electronic parts. For further information contact Grand Rapids React at the above address.

FRAMINGHAM MA
APRIL 2

The Framingham Radio Club will be holding an Electronic Flea Market on April 2, 1977 at the Framingham Civic League building, 2 miles south of Rt. 9 on Rt. 126. The doors will be open from 8:30 until 12:30 with a $1 admission fee. For advance indoor table reservation send $5 to W. R. Armstrong, 386 Howard Street, Northboro MA 01532.

COLUMBUS GA
APR 2-3

The Columbus, Georgia Hamfest will be held April 2 and 3, Palm Sunday weekend, at the Fine Arts Building at Fairgrounds, 9 am to 4 pm daily. Flea market, ham auction, prize drawing at 1:30 pm Sunday, talk-in 28/88, 3975 kHz, buffet dinner Sat. at 8 pm. For more information write K4JNL. Advance tickets: K3MTY/4, Rt 5, Box 750, Phenix City AL 36867.

TOWSON MD
APR 3

The Greater Baltimore Hamboree will be held Sunday, April 3rd at 9 am at Calvert Hall College, Goucher Blvd. and La Salle Rd., Towson MD 21204 (1 mile south of Exit 28, Beltway-Interstate 695). Food service, prizes, giant flea market. Admission charge S2. 225 tables inside gym. Over 1700 attended last year. Information and table reservation: Contact Bro. Gerald Malseed W3WVC at school address or call 301-825-4266.

ST. CLAIR SHORES MI
APR 3

The South Eastern Michigan Amateur Radio Association is holding its Nineteenth Annual Hamfest on April 3, 1977 from 8 am EST to 3 pm EST. It will be held at the South Lake High School in St. Clair Shores, Michigan, 21900 Nine Mile Road and Mack Avenue. For further information contact Dorothy Spilski WB8PRJ, Secretary S.E.M.A.R.A., 11906 Riad Avenue, Detroit, Michigan 48224, 313-521-6646.

CANBERRA
AUSTRALIA
APR 8-11

The ACT Division of the WIA would like to announce that the Canberra Easter Convention will be held April 8-11 in Canberra, Australia. There will be plenty of time for sightseeing embassies, the lake, the Captain Cook Memorial Water Jet, etc. For more information contact: Canberra Easter Convention, Post Office Box E338, Canberra, ACT, 2600.

RALEIGH NC
APR 16-17

The fifth annual Raleigh Amateur Radio Society Hamfest will be held April 16-17 at the Crabtree Valley Shopping Center, lower level rear, on highway 70W. FCC exams will start at 12:30 pm, Saturday sharp, by appointment only through the Norfolk FCC district office. There will be an eyeball social and doorprizes Saturday night between 7 pm and 12 pm. An expanded covered fleamarket, meetings, ladies program, and over 100 prize awards on Sunday from 9 am to 3 pm. For additional info contact: RARS Hamfest, P.O. Box 17124, Raleigh, NC 27609.

MOBILE AL
APR 16-17

The Mobile Amateur Radio Club will hold its annual Ham Fest and Computer Fest on April 16 and 17th — all the newest equipment on display, computers too. Swap & Shop all day Saturday from 9 to 5, banquet at 7 pm, doors open Sunday at 9 am, prizes, drawing at 1 pm. Activities for the ladies and children, campsites available, over 1500 people expected, the biggest Fest on the Gulf Coast. For more information contact Marvin Uphaus K4BVG, 512 Tuttle Avenue, Mobile AL 36604.

LIBERTY MO
APR 23-24

The P.H.D. Amateur Radio Assn., Inc., of Liberty MO (Kansas City area) will sponsor the Eighth Annual Northwest Missouri Hamfest on Saturday and Sunday, April 23 and 24, 1977 at the Kansas City Trade Mart, Exhibit Hall 2 (Municipal Airport terminal building). There will be a complete program of forums both days, a large number of commercial exhibits, swap tables, YL-XYL program. Doors open from noon to 6 pm on Saturday, April 23; and from 9 am to 5 pm on Sunday, April 24. Setup time for commercial and swappers will be from 10 am to noon on Saturday. There will be a Saturday night banquet at the world famous Gold Buffet, with ARRL president Harry Dannals W2HD, as guest speaker. Pre-registration is S2, admission at the door will be $2.50. Pre-registration including banquet is S8. Talk-in on 146.34/.94 and 3.925 MHz. For information and pre-registration write to: PHD Amateur Radio Assn., PO Box 11, Liberty MO 64068.

GREENVILLE SC
APRIL 24

The Blue Ridge Radio Society of Greenville SC announces its annual hamfest for 1977. The event will take place April 24th at the Thunderbird Motel on Highway 291 in Greenville. A flea market and dealer's display area will be featured at the motel. Doors open at 8 am.

SULLIVAN IL
APR 24

The Moultrie Amateur Radio Klub will have its 16th Annual Hamfest Sunday, April 24th at Wyman Park, Sullivan, Illinois. Heated indoor area and large outdoor parking area. No charge to vendors. For information write: MARK Radio Klub, PO Box 327, Mattoon IL 61938. Talk-in 146.94.

AMBOY IL
APR 24

The Rock River Radio Club Hamfest will be held April 24, 1977 at Amboy, Illinois (Lee County), at the 4H Center, Routes 30 and 52. Same place as last year. Tickets S1.00 advance. $2.00 at gate. Camper parking available at a nominal fee. Write: Carl Karlson W9ECF, Nachusa IL 61057. Indoor and outdoor facilities.

LAS CRUCES NM
APR 24

The Mesilla Valley Radio Club sponsors Whitey's Bean Feed and Swap-Fest Sunday, April 24th, at 10 am. Located near Las Cruces, New Mexico at La Mesa with talk-ins on 16-76, 04-64 and 3940 kHz. Fun for all the family with big prizes, plenty of food and the usual beverage truck. All included for $5.00 for adults, S1.75 for kids. Eat, drink and win a prize with Whitey K5ECQ as host. Free overnight parking at grounds so come for a spell. All correspondence should be made to: Thomas B. Rapkock Jr., 640 W. Las Cruces Avenue, Las Cruces NM 88001.

DAYTON OH
APR 29

The 8th Annual FM B*A*S*H will be held on the Friday night of Dayton Hamvention, April 29, 1977, at the Dayton Biltmore Towers (hotel), Main at First Streets, from 8 pm til midnight. Admission is free to all hams and their friends. Sandwiches, beverages, snacks and C.O.D. bar will be available. A live floor show will be presented by TV personality Rob Reider WA8GFF and his group. It will be followed at 11 pm by a fabulous prize drawing featuring an Icom IC-245 and many others. See you where the action is!

BROWNFIELD TX
MAY 1

The Brownfield Amateur Radio Club will hold a Swapfest on Sunday, May 1, 1977, in Brownfield, Texas.

WEST TRENTON NJ
MAY 1

The annual Delaware Valley Radio Association (W2ZQ/WR2ADE) flea market and auction will be held on Sunday, May 1, 1977, 9 am rain or shine at the Villa Victoria Academy in West Trenton, New Jersey (the school is located adjacent to Rt. 29 near the junction of Rt. 29 and I-95). Talk-in on 07/67 and 146.52. Refreshments are available. Advance registration $1.00; $1.50 at gate. For additional information or tickets write: DVRA, PO Box 7024, West Trenton NJ 08628, SASE please.

FRESNO CA
MAY 6-8

The Annual Fresno Amateur Radio Club Hamfest will be held this year at the Airport Holiday Inn on May 6 and 8, 1977. For more information write Fresno Amateur Radio Club, Inc., 4788 N. Safford, Fresno CA 93704.

MEADVILLE PA
MAY 7

The Third Annual Northwestern Pennsylvania Hamfest will be held May 7 at Crawford County Fairgrounds, Meadville PA. Free admission. Flea market begins at 10 am. $2 to display — hourly door prizes — refreshments — commercial displays welcome. Indoors if rain. Talk-in 146.04/64 and 146.52. Details C.A.R.S., PO Box 653, Meadville PA 16335.

SUPERIOR WI
MAY 7

The Twin Ports Two Meter Club will hold its Second Annual Swapfest on Saturday, May 7, 1977, in the hall of the Duluth First Methodist Church from 11 am to 3 pm. Pre-registration and door prizes will be awarded. Admission is S1.00 in advance and S1.25 at the door. Selling space is S1.50 additional — $1.00 with your own table. Food available on the premises. Plenty of parking. Talk-in on 34/94. For flyers and/or tickets, contact Twin Ports Two Meter Club, c/o Libby Welsh WB9MLN, 525 Homecroft Court, Superior, Wisconsin 54880.

BINGHAMTON NY
MAY 7

The 18th Annual STARC Hamfest will be held Saturday, May 7, 1977 at Binghamton, New York. Take exit 71N from NY-17, go 3.8 miles north on Stella-Ireland Road. Flea market, tech talks, hourly door prizes. General admission S2.00/person. Banquet by pre-reservation at S6.00/person. Indoor exhibit space by pre-registration at S5.00 per table. Outdoor exhibit flea market space free. Talk-in 146.22/82 and 94/94. For details and reservations, contact STARC, PO Box 11, Endicott NY 13760.

HERNDON VA
MAY 7

The Potomac Area VHF Society will hold its sixth annual hamfest on Saturday, May 7, 1977, from 8 am to 5 pm at Frying Pan Park on West Ox Road in Herndon, Virginia, which is approximately 15 miles west of Washington DC. Registration of $3 includes flea market or tail gate sales. Professional food and beverage catering and unlimited parking will be available. Talk-in on 146.52 and 31-.91. repeater. This is the hamfest formerly held in Westminster MD, but moved to Virginia because of the recently en-

acted Maryland traders law. For further information contact K3DUA or WA3NZL.

BIRMINGHAM AL
MAY 7-8

The Birminghamfest Amateur Radio Convention will be held May 7 and 8, 1977 at the Alabama State Fairgrounds, Birmingham and Rodeway Inn, Oxmoor at I-65 and Oxmoor Road. One of the country's largest flea markets, technical and operating forums, huge prize drawing, manufacturers' and distributors' displays, ladies' and children's activities. Booth display area will be offered free of charge to bona fide distributors, manufacturers, publishers, etc., on a first-come, first-served basis. Others may rent space in inside or outside flea market areas at a small charge. No admission charge. Prize ticket donations — $1. Talk-in 34/94, 3965 kHz. For booth display space, information, and reservations, write: Birminghamfest, PO Box 603, Birmingham AL 35201.

WARMINSTER PA
MAY 15

The Warminster Amateur Radio Club's "HAMMART," Flea Market and Auction will be held Sunday, May 15 from 9 to 4 at William Tennent Intermediate High School, Street Road (Route 132), 2 miles East of York Road (Route 263), Warminster, Bucks County, Pa. Registration $1, tailgating $2 additional. Talk-in on 147.69-09; 146.16-76 and 146.52. For further information write to Horace Carter K3ZAC, 38 Hickory Lane, Doylestown PA 18901.

SANTA BARBARA CA
MAY 13-15

The 22nd annual West Coast VHF Conference will be held on May 13-15, 1977 at the Miramar Hotel on the beach in Santa Barbara CA. The event opens with registration at 6 pm Friday (May 13), followed by a full day of technical presentations starting at 9 am, Saturday. Pre-registration fee is $2 until April 30. After that and at the door, $3. Registration forms, hotel information, and further details may be secured by writing Dr. Overbeck at the Communication Division, Pepperdine University, Malibu CA 90265.

VANCOUVER WA
MAY 21-22

The Fort Vancouver Hamfair will be held Saturday and Sunday, May 21 and 22 at the Clark County Fairgrounds, 7 miles north of Vancouver on I-5. Sponsored by W7AIA, Clark County Amateur Radio Club, in cooperation with W7KYC, Portland Amateur Radio Club. Camping, contests, swap & shop, prizes, displays, and many other activities. Registration donation $3. Send registrations to Dorman Stafford W7ZDR, Registration Chairman, Fort Vancouver Hamfair, 3509 E 21st St., Vancouver WA 98661. Make checks payable to Fort Vancouver Hamfair. Talk-in on 2 and 75 meters.

An FM Gadget

-- timer for the long-winded -- plus!

Bruce Fette WA7NMO
2310 W. Del Campo
Mesa AZ 85202

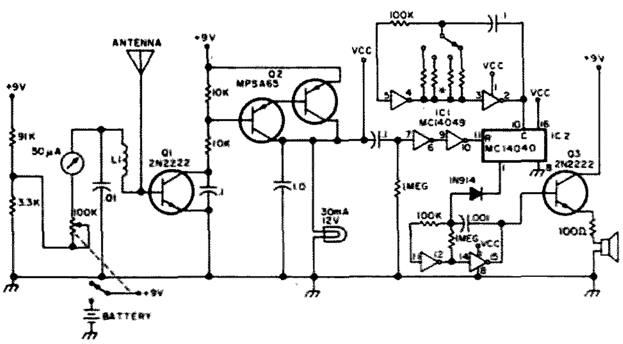

*Fig. 1. L1 = 3 turns #20 on 5/16" form. *Timing resistors:*

R	*Time-Min*	*Freq. Osc. Hz*
47k	*.5*	*82*
100k	*1.0*	*37*
220k	*2.0*	*18.6*
390k	*3.0*	*12*
510k	*5.0*	*7.3*

A field strength meter is a universal instrument in any ham radio shack. It tells you when your final transistor goes soft due to high swr, when your push-to-talk switch goes bad or the connector gets flaky, and the most insidious of all, when the swr shuts you off. But how many hams use their field strength meters?

This design promises to be a more useful ham shack toy than most. In addition to being an FSM, it is a timer to let you know when you have talked too much. This function is particularly useful to several Phoenix hams.

The front panel indicates relative field strength with a sensitivity adjustment, has a switch for time out ranging from .5 to 5 minutes, and displays an on-the-air light. At the end of the selected time-out interval (cleverly chosen to be equal to your neighborhood repeater), an internal loudspeaker signals a tone indicating "time out." So let up on the mike.

Circuit Operation

The antenna drives the base of Q1, which rectifies the signal and provides meter current. The sensitivity is adjusted by the 100k pot. The presence of base current turns on Q1, discharging the .1 uF capacitor in its collector and providing base current for Q2. The .1 uF capacitor could be as large as 100 uF, forcing you to let up on the mike button for one second before it would reset the timer.

When Q2 turns on, it provides current to the "on-the-air" lamp, a lamp carefully selected to draw 30 mA at 9 V so that it doesn't drain the battery. It also provides current to the CMOS integrated circuitry to begin timing the transmission. The timer consists of a hex inverter (MC14049) and a 12 bit ripple counter (MC14040). The combined current drain of these circuits is 1 mA consumed in the timebase oscillator. When Q2 turns on, an 8 V jump in voltage is coupled through the .1 uF capacitor to pin 7 of IC1, but slowly discharges to ground in .1 sec through the 1M resistor. The two inverters (7-6, 9-10 of IC1) square this pulse to reset all stages of the IC2 counter. An oscillator consisting of two inverters (5-4, 3-2 of IC1) runs at the frequency shown in Table 1. IC2 counts the cycles of this oscillator. On the 2049th count, Q12 of this counter will go high, and no longer will disable the audio oscillator (500 Hz, 11-12, 14-15 of IC1).

When this oscillator runs, a square wave is produced at pin 15 of IC1 which is buffered by Q3 to drive the loudspeaker. A resistor is used to limit the current to the loudspeaker, but lower values (or a transformer) would be required for adequate audio in mobile operation.

This unit was built into a Radio Shack minibox (1-5/8" x 2-5/8" x 5-1/8"), but that is a tight fit. The majority of the circuitry was built on one PC card. All ¼ Watt resistors and chip capacitors were used to keep down the size, as well as the smallest loudspeaker I could find. A 9 V alkaline battery is used for long life. The ICs should be kept wrapped in aluminum foil until ready to be soldered in (after all other parts have been soldered in). Pin 6 of IC2 must be cut off the IC, or bent away from the hole before it is inserted and soldered in. Solder pin 8 of the ICs first, thus grounding the static protection devices inside. Grid dip the tuned circuit to put it on the appropriate band or use values shown for 2m. The capacitor in this tuned circuit should be retweaked for maximum sensitivity with an on-the-air signal. On 2 meters the base emitter capacitance of Q1 is almost enough to tune L; however, adjustment of the antenna from ¼λ will optimize the sensitivity. ■

The Real Truth About SWR

- - if the transmitter loads okay, forget it

H. A. Ray WB5IAM
1406 San Rafael
Dallas TX 75218

Everyone writing on swr states some truths but invariably adds more mystery and confusion to the subject in the process. There is no question about whether energy or power flows in both directions on a transmission line. The existence of standing waves on the line is a summation of the forward and reverse waves and can be predicted with mathematical accuracy.

The confusion is in what the swr meter is saying to us. It is saying that "potential" energy is passing the meter in both directions and *if* this line were terminated at both ends in its characteristic impedance, that energy would be dissipated at a certain rate (which is called power). Note the *if*.

Let us take a few examples. If we have an infinitely long line with no loss and we turn a transmitter on for one second, a block of energy 186,000 miles long would propagate down the line and keep going long after the transmitter was shut off. The forward swr meter would read the transmitter power for one second as the block passes it. The meter simply says that *if* the far end of this line is terminated in its characteristic resistance, there would be the transmitter power in Watts dissipated in this resistor for one second when this energy block reaches it. It is perfectly respectable to call this energy flow, but it must be called "potential" energy and, at a certain time rate, "potential" power.

The forward swr meter doesn't know whether power was extracted at the far end or not. If the far end of the line is open or short circuited, then all of this potential energy will reflect and flow as a block in the reverse direction on the line. Now, suppose we turn the transmitter on for one more second. We now have two blocks of energy flowing toward each other. When they meet they will cause a standing wave on the line for one second where they overlap.

Now, let's turn the transmitter on a third time just as the first block of energy reaches its terminals. Depending upon the transmitter matching conditions, the first block of energy will reverse and combine with the transmitter power. We now have a new block of energy which will be read by the forward swr meter as greater than the transmitter power. This is not surprising, as we know part of it came from the transmitter and the rest of it was the reverse power, reversing again when it hit the transmitter.

This is not just a fictitious example. Time domain reflectometers show us pictures of the forward and reverse energy flow on lines. In fact, all calculations of impedance and standing waves on lines are derived from the forward and reverse energy flow on transmission lines.

Standing wave meters are just what they say they are. They show the magnitude of the forward and reverse waves which are propagating on the line and they convert this to the power that could be absorbed *if* the line were terminated in its characteristic impedance.

The above example illustrates that on a good line with large conductors or on a lossless line, there is no power loss due to large swr or reflected power. The power delivered to the line simply flows back and forth until it is dissipated in the antenna or load. Large standing waves produce points of high current on the line. The current squared times the resistance of the copper wire at this point is the loss in Watts. It is usually insignificant on amateur transmission lines. If the transmitter will load up to power, forget the swr. ■

Improving the Dipole

- - omnidirectionalization modification

73 Magazine *Staff*

Any dipole antenna, when it is reasonably well elevated, exhibits very definite directional properties. Maximum radiation occurs broadside (or at right angles) to the line of the antenna and minimum radiation occurs in-line or off of the ends of the antenna. Some amateurs put up a dipole antenna to take advantage of the directional properties of this type of antenna. But most amateurs really only put up a dipole antenna because it fits into the space available for putting up a simple antenna. The directional properties are simply a disadvantage of the antenna which have to be accepted. Most amateurs with restricted space available would probably prefer a good omnidirectional antenna for general purpose work on any one band. The vertical antenna is one solution, of course, but it requires a good ground system to be effective and should also be constructed in an area which is reasonably free of obstructions. Obstructions around the ground end, or high current and hence high radiation portion, of a vertical antenna are particularly destructive of its real efficiency. Vertical antennas are also not the least conspicuous of antennas, in situations where that is a consideration, as compared to a wire-type dipole antenna. So, what to do about making a simple dipole antenna have a better general-purpose omnidirectional radiation pattern? One possibility is to construct the dipole antenna in an inverted V fashion with the center point at the most elevated position and the sides having about a 90 degree angle to each other. A fairly omnidirectional pattern will result but with reduced radiation, as compared to a regular dipole, both broadside to and off the ends of the dipole. An alternative solution is the form of extended dipole antenna presented in this article. It offers broadside radiation efficiency equal to that of a regular dipole, radiation in the "off of the ends" direction only 3 dB down from the broadside radiation, and is extremely easy to construct or add to an existing dipole.

Some old-timers will remember when horizontal polarization was the accepted practice on VHF. Many antenna forms were developed for mobile use to achieve horizontal polarization and yet obtain a reasonably uniform omnidirectional radiation pattern. Most such antenna forms have long since faded into obscurity, but two of them still retain some degree of significance. By far, the most remembered form is the turnstile or crossed dipole configuration (Fig. 1). By properly current phasing two dipole (or folded dipole) antennas erected horizontally and at right angles to each other, one could obtain an almost omnidirectional pattern with the gain in any direction almost equal to that of an individual dipole. The design is still used for some omnidirectional type FM antennas. The second, and usually most forgotten, type of omnidirectional type of horizontally polarized dipole antenna is shown in Fig. 2. It lends itself particularly well to adaptation to HF wire type dipole antennas, although it seems to have practically disappeared from the VHF scene once the latter went "vertical" for most amateur radio usage.

The antenna form is simply that of a regular half wave dipole flat-top with quarter wave extension legs added vertically at each end of the basic dipole. The extension legs should be at right angles to the flat-top to achieve the best omnidirectional pattern, although if they are displaced by about 30 degrees or less no great harm will result. Preferably, the bottom ends of the extension legs should be themselves about a quarter wave above ground if the radiation off the ends of the antenna is to remain also horizontally polarized. If this distance is less, there still will be significant radiation off the ends of the antenna but its polarization will be a combination of horizontal and vertical components.

Changing the overall length of a dipole antenna will, of course, change the feed point impedance seen at the center of the antenna.

Any of the various matching methods described in antenna handbooks can be used to re-match the coaxial feedline normally used with an unmodified dipole to the modified dipole. One of the simpler methods which has worked out well in practice, however, is the use of a quarter wave matching section made from 300 Ohm

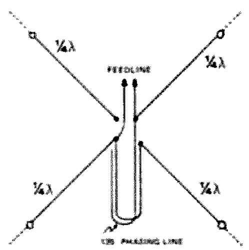

Fig. 1. Turnstile is an excellent form of omnidirectional dipole but obviously difficult to support since four elevated support points are needed.

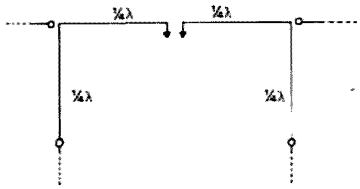

Fig. 2. Two vertical quarter wave sections are added to regular half wave horizontal dipole. Change in dipole feedpoint impedance must be compensated for.

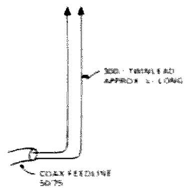
twinlead between the antenna and coaxial line as shown in Fig. 3. One should be prepared to do a bit of pruning of the 300 Ohm matching section. Start with a full quarter wave section and cut it back a bit at a time until an swr meter placed in the coaxial line shows the lowest reading. A balun transformer can be used between the coaxial line and the 300 Ohm twinlead for balance purposes if desired. Be sure to use a 1:1 ratio balun. The idea is not to use a 4:1 setup balun to match the coaxial line to the 300 Ohm section, as this would prevent the latter from acting itself as an impedance transformation device between the coaxial feedline and antenna.

When adding the extension legs to an existing dipole, they can be simply secured to the ground using a length of heavy duty plastic clothesline to keep them in position. Such line has enough give to it to act as a spring and thus keep moderate tension on the extension wires. Clothesline with a nylon core and not that with a metal core should be used.

Fig. 3. Needed matching line for dipole in Fig. 2. Twinlead length should be trimmed for lowest swr.



This dipole modification is not new. It has been used with success over a number of years in different installations. Although no comparison was made with a dipole oriented at right angles to a modified dipole, stations could be worked off the ends of the modified dipole which could not be worked before modification. ■

The 60 WPM Conversion

- - using 100 TTY on 60 wpm circuits

By now you have more than likely been hearing about the UART. This is, in long form, Universal Asynchronous Receiver Transmitter. This chip can receive, serially, signals with start and stop pulses of any 5, 6, 7 or 8 level data. The Baudot code used on amateur RTTY is (5) five level. Which it will work on is determined by putting a jumper on the chip or leaving it off.

The receiver's input recognizes serial input and converts it to parallel. This output is available on pins 26, 27, 28, 29, 30, 31, 32 and 33. The speed at which the receiver will operate is set by the frequency of pulses that one applies to pin 27. This is determined by multiplying 16 times the baud rate of the speed you wish to operate. To calculate this, use 7.5 as your unit per character of (5) five level code. For example, if you want 60 wpm, that is one word per second. One word in RTTY is five characters plus one character for space that must be printed, or six characters per second. Six x 7.5 equals 45 baud; 45 x 16 = 727 Hz.

The transmitter's input is parallel on pins 5, 6, 7, 8, 9, 10, 11 and 12. Its output is serial, with start and stop pulses on pin 25. The speed at which the transmitter operates is set by the frequency of pulses applied to pin 40. This tool is 16 times the baud rate of the speed you wish to operate. For example, if you wish to run 100 wpm, that is six characters per word, equaling 600, which divided by 60 seconds gives you 10 characters per second, which times 7.5 equals 75 baud. Multiply this by 26 and it gives you 1200 Hz. To make life easier, use the formula:

$$\text{FREQ} = \frac{\text{OPM} \times 16 \times 7.5}{60}$$

Remember, FREQ is the clock frequency you want in Hertz and OPM is the operation per minute you wish to run. For example, six characters per word, 100 words per minute, is 600 OPM. Six characters per word at 60 wpm is 360 OPM.

Now that we have all this, what are we going to do with it? The easiest thing would be to connect the parallel output of the receiver to the input of the transmitter. If we clock both at the same speed we have just made ourselves a regenerative repeater. This does not excite many hams at first, but let's go over it a bit.

Irv Hoff W6FFC and Howard Nurse W6LLO, as well as Paul Satterlee, Jr. WA5IAT, have written two very good articles on the UART in the *RTTY Journal*, April and May, 1974, issues. They say "most companies claim that signals within plus-minus 47-48 percent bias can be handled with perfect output timing being generated in the transmit section." In marginal copy, there should be a significantly fewer number of errors printed. By clocking the receiver and transmitter at different frequencies, we can build a digital speed converter to either go up or down in speed.

The schematics in this article should enable you to build a digital speed converter. You will note that I have added a FR15202E FIFO (First In First Out). This is only a 40 character 9 bit storage chip. As you load each 8 bit character into the input, it just drops through until it hits the output. Or, if there is memory in it, it will load up to that point.

Just think of it as a long hollow tube that you drop ping pong balls into. They will fall to the bottom if there are no other balls in the

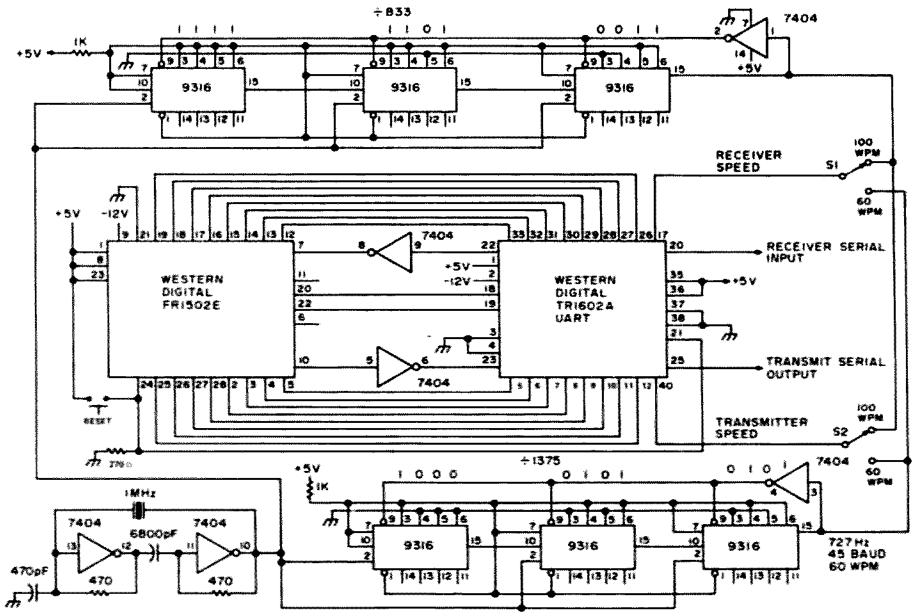

Fig. 1. Speed changer.

way. The UART will release the balls one at a time as it wants them, via pins 22 and 23. The purpose of this is that when you are keying at 100 wpm and sending at 60 you will have a 40 character storage. The whole idea of this circuit is to run your machine at 100 wpm. Now you can copy 60 wpm or 100 wpm by changing the clock frequency of the receiver, and be able to leave the transmitter output at 100 wpm. You can also connect up your 100 wpm keyboard to the receiver and transmit either 100 wpm or 60 wpm by changing the clock frequency of the transmitter and be able to leave the receiver at 100 wpm.

The only problem you might run into is if you run a TD at 100 wpm and transmit at 60 wpm. You can see that if you did that you would soon fill up the FIFO. You could build up a circuit that would recignize a filled up FIFO and stop the TD for a preset time. If you are typing on the keyboard, you will have to take a break once in a while if you type faster than 60 wpm for more than 100 characters at a time. I don't seem to have any trouble there, but I think a fast typist might have to slow down. The reset is used when you first turn the unit on, as you don't know what will be loaded in the FIFO.

Both frequencies are divided down from the 1 MHz clock. Any clock frequency you want can be used as long as you divide it down to the ones we discussed. If you don't like the clock I am using, there is a very good one by Irv Hoff W6FFC called the Mainline XB-6 UART Clock in the May, 1974, issue of the *RTTY Journal*. The 9316s are programmable dividers by Fairchild. For those who don't know how to program these dividers, let's look into them a bit.

The idea is to program dividers up so that when they reach the number you want, the output of the last device goes high. You use this output to feed back or reset the dividers back to the programmed number. Since the input is a crystal clock, you can see now that the output should be as stable as the input but divided by the preset number entered into the divider.

To calculate how to program the divider, you first convert the divisor to binary. Then take the 2's complement of this number and load it into the dividers. Each divider is a divide by 16, so you must load 4 binary codes into each one. The program inputs to each chip are pins 3, 4, 5 and 6. Pin 3 is the least significant number and pin 6 is the most significant number. A 1 is loaded as +5 and a 0 is connected to ground. Let's go over one to be sure you understand it.

To get 1200 Hz for the 100 wpm clock, we first divide this into our clock frequency of 1 MHz. This comes out to 833. Now this means we must program our divider to give us an output at every 833rd count of the clock. If you look at the circuit, you will see that this will also give us the feedback for the reset pulse. The easiest way I know of to convert 833 to binary is to just keep dividing by 2. If 2 divides into it evenly it is 0; if you have a remainder it is 1.

For example:

```
        1 - - - 1   MSN
      2 |3 - - - 0
      2 |6 - - - 1
     2 |13 - - - 0
     2 |26 - - - 0
     2 |52 - - - 0
    2 |104 - - - 0
    2 |208 - - - 0
    2 |416 - - - 1   LSN
    2 |833

ADD
0001 - 0100 - 0001
1110 - 1011 - 1110
                +1
------------------
1110 - 1011 - 1111  2's Complement
     REVERSE
1111 - 1101 - 0111  LOAD
```

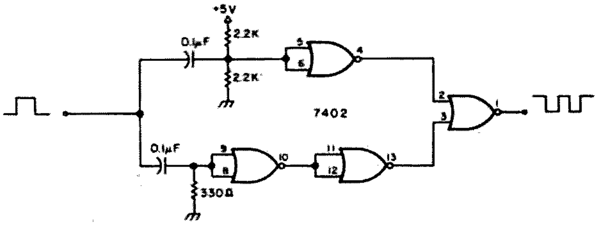
Note that the answer came out to only 9 places. You must add the three 0s to make it come out to 12, as each chip has 4 inputs and they must all be set. If the answer had come out to 8 places, we would have had to only use 2 chips. Now to get the 2's complement we invert all the digits — that is, make every 0 a 1 and every 1 a 0. We then add 1 to the least bit and we now have what we want. There's only one problem: They are in reverse. If you look at the circuit, you will note the LSB is pin 3 of the 1st chip and the MSB is pin 6 of the 3rd chip. What we have to do now is just reverse all the digits end for end or tip the sheet of paper upside down. If you want to get fancy, you could put a series of switches on the program inputs and then be able to pick out any frequency of pulses wanted.

There are many ways to interface the UART to the Mainline TT/L or ST-6. Several are in the May, 1974, issue of the *RTTY Journal*. Remember that the input and output are TTL compatible and you can operate the UART with any circuit that will work with TTL logic. Input is +5 volts and is pulled to ground to operate. The output is +5 volts when not being pulsed and goes to ground internally when operating. I am going to operate my unit in a separate cabinet with its own loop supply and optoisolator so it will be independent of my ST-6. Think I could use it better this way. Most people might like to put it into their ST-6, as you already have the 12 V. Coming up with +5 should be no problem. To operate the circuit you will need about 30 mA of 12 V dc and 50 mA of +5 V dc. This should be well-filtered and well-regulated.

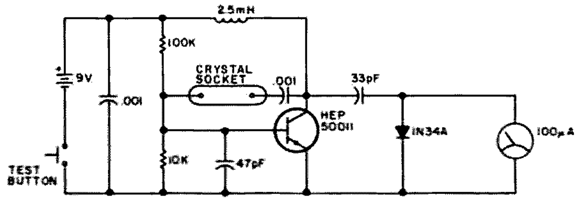
I would like to thank Bob Davis W6HUL for all the help he gave me on this article. Without his knowledge, it would not have been possible. ■

Circuits²

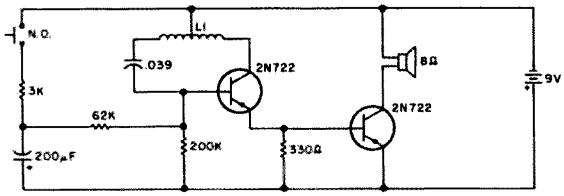
Want a free copy of any 73 publication? Sure you do. Just send in your favorite circuit, or even one that you don't especially like. If we print it, you take home the book of your choice.



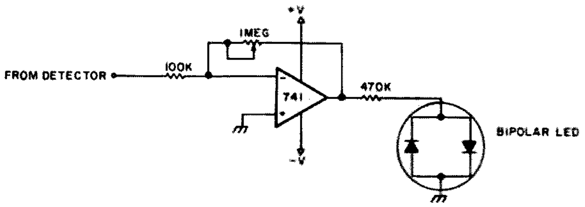
Here's a circuit developed for doubling the frequency of a TTL square wave. It locks onto the rise and fall of the input square wave. If high frequency operation is desired, the capacitors may be lowered in value. Thanks to Howard Gerber WB5YWS.



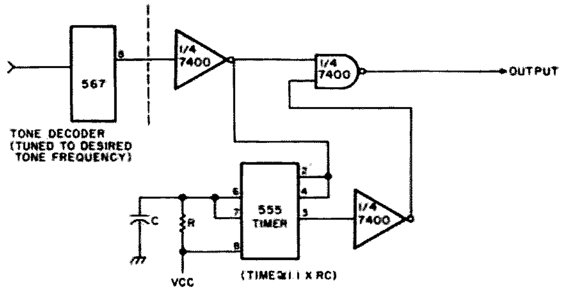
A crystal checker suitable for checking used crystals at hamfests, etc. If the crystal is good, the meter will show a steady indication. A good crystal will cause the circuit to oscillate when the "test" button is pushed, with a half scale reading on the meter. Thanks to John Mairs, Springfield VA.



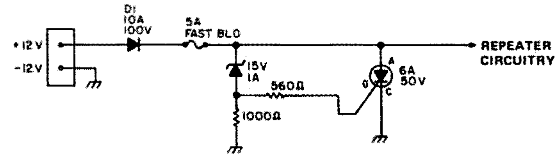
A siren oscillator that sounds just like an air mechanical device. L1 is one half an audio transformer with a 10k center tap. Thanks to Gary Capek K8NSA/5.



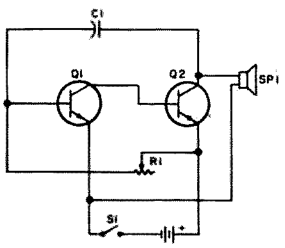
A zero center indicator for FM receivers. To adjust, tune in a station and adjust the 1 megohm pot for a null. Then ask the station to modulate and fine adjust so modulation peaks don't light the LEDs. Stations are properly tuned when neither LED is lit. Thanks to Michael Black VE2BVW.



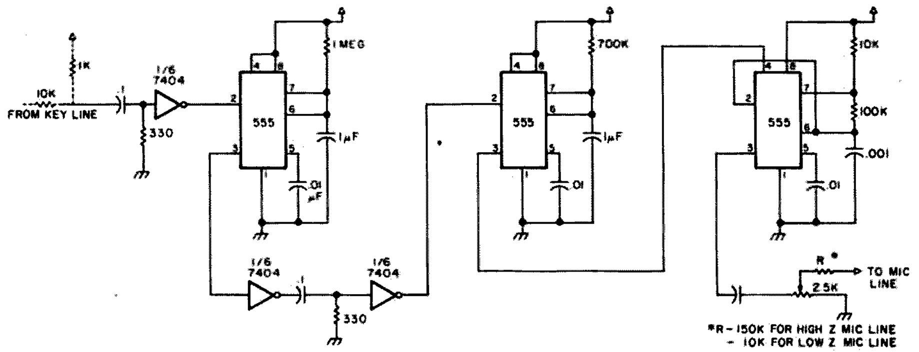
A continuous tone detector using 567, 555, and 7400 ICs. The output goes low only when the tone has been continuous and exceeds the timer pulse. Without a tone, the high at the 567 output is inverted, keeping the timer reset. When the tone comes in, the timer output goes high and, after being inverted, blocks the gate. If continuous tone is used, the gate is opened at the end of the timer pulse. If not continuous tone or shorter in duration than the timer pulse, the output of the gate remains high. The circuit could also be used to reset an alarm system or detect any TTL logic that required a specific length of time. Thanks to Raymond Thompson KH6IEL.



The best way yet to safeguard portable, emergency power repeaters from reverse or excessive voltage. D1 prevents incorrect polarity damage, and zener voltage determines the maximum voltage that will reach the rest of the circuitry. Use fast blowing fuse rated greater than the SCR current rating. Thanks to Paul Hurm WB8CLF.



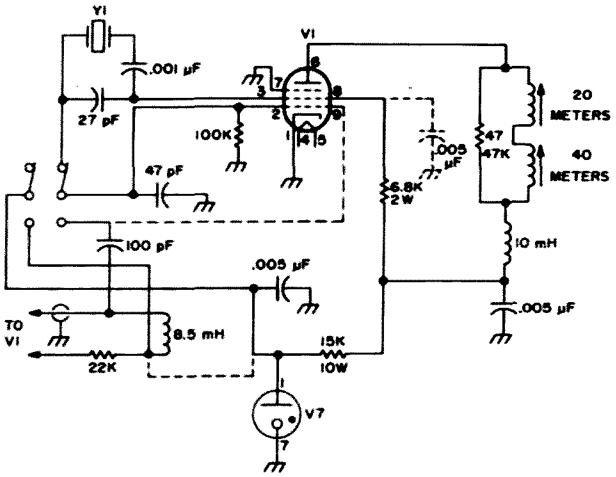
Your basic code practice oscillator, which works with 2 to 12 V dc (but 9 to 12 volts gives best volume and clean keying). R1 can be replaced with a 500k pot and the circuit will sweep the entire audio frequency range. Thanks to Rod Hallen, Tombstone AZ.



The "Key Up Beeper," designed for use on the Jacksonville FL 16/76. The circuit gives a .75 second tone burst 1 second after the COR is de-energized. Time delay may be changed by substituting another value for the 1 megohm resistor. Tone burst duration is varied by changing the value of the 700k resistor, and the frequency of the tone is changed by varying the resistor-capacitor ratio of the third 555 IC. The circuit is set up for 5 V dc, but can be used for 12 V dc applications by adding the components in dashed lines. Thanks to Jim Arner, Jacksonville FL.

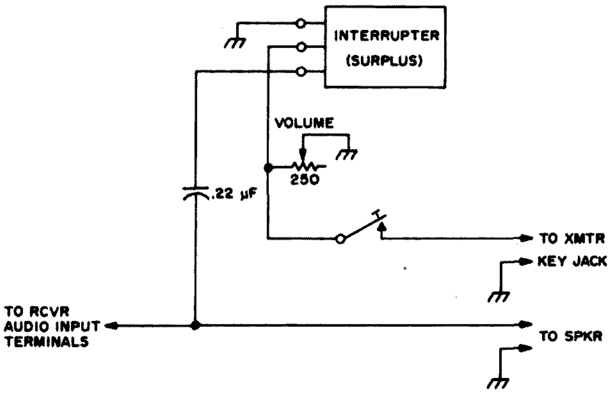
Q&A

This column will be a monthly feature of 73 Magazine. It is hoped that it will be of assistance to beginners and old-timers alike. We only ask that your questions be kept as general as possible. We will try to answer all queries received. Please mail your questions to Technical Editor, 73 Magazine, Peterborough NH 03458.



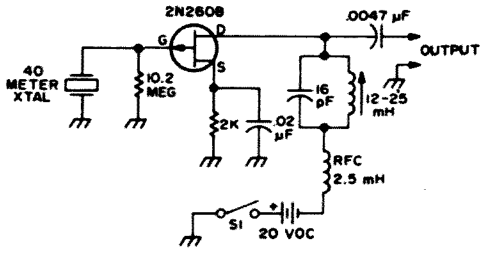
Q. For operation on MARS, CAP, etc., what modifications will allow crystal-controlled as well as vfo operation?

A. This typical-circuit modification (see the figure) will permit crystal-controlled operation and requires only a few small parts for a very worthwhile addition. And, original calibration of the set's vfo is undisturbed.



Q. Is there a diagram for constructing a simple keying monitor?

A. The interrupters in several pieces of surplus equipment, such as telegraph set TG-5, can be converted easily to an excellent keying monitor used with the station receiver and transmitter, as shown in the figure.



Q. Is there a crystal oscillator circuit that will operate at 7 MHz using a Siliconix 2N2608 field effect transistor (FET)?

A. The oscillator circuit in the figure will work very well. Leads must be kept short. The coil can be air-wound or a permeability-tuned unit. If desired, the tuning capacitor can be a variable unit and the value of the coil fixed. The amount of rf output will depend on the crystal (activity) and the voltages used.

Q. What is an integrated circuit?

A. An integrated circuit (IC) is a small piece of a specially treated mineral that has the ability to reproduce entire circuits that might ordinarily require dozens of transistors, resistors, and other components. There is at least one IC that is the size of a transistor that actually replaces a thousand transistors; some replace even more. Being very small, they are perfect for miniaturized construction projects or for simplifying larger projects. Usually they have fourteen or sixteen connections.

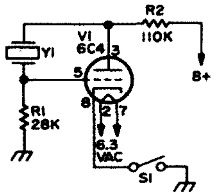
Q. How can a surplus frequency meter rf output be reduced?

A. Simple. To recap, however, the problem occurs when the instrument is tuned to a weak signal. What happens is that a heterodyning effect is produced — and quite an annoying one.

To remedy, a 2 megohm potentiometer should be placed in series with the original screen dropping resistor in the frequency meter. To null or reduce output, merely adjust the newly-installed potentiometer.

Q. If any, what are the advantages of SSB compared to FM?

A. First of all, FM requires more frequency space and more bandwidth. Second, performance of SSB on weak signals is better than FM. Lastly, FM cannot be received properly on an ordinary AM-CW receiver — SSB can, by using the bfo to inject carrier.



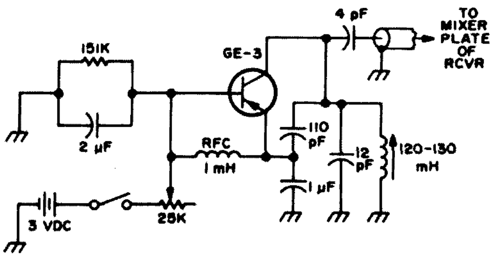
Q. How can you set the main tuning dial to the right spot so that the calibration of the bandspread dial will be accurate?

A. A crystal-controlled marker oscillator (see the figure) is about the best way to do this. The circuit shown can be built right into most receivers and turned on or off at will with a toggle switch mounted on the front panel.

A 3.5 MHz crystal will work nicely. The fundamental and harmonics of the 3.5 MHz oscillator make it usable as a band edge marker for all bands through 28 MHz.

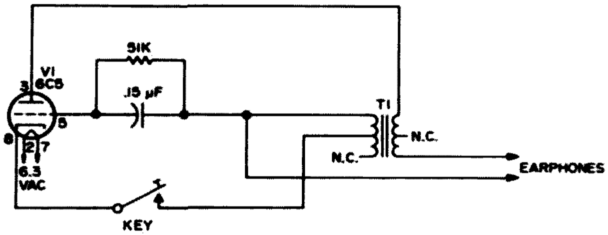
Q. Is the problem of key clicking, experienced with CW keying, also experienced in FSK work in teleprinter operation?

A. Yes, shifting frequency too quickly will result in sharp-edged waveforms. In order to achieve rounded characters, the keying transition must be smooth and slow. Abrupt changes in any keying signal will produce excessive bandwidth, and result in thumps or clicks, even though the affected receivers are tuned to a frequency some distance from the offending station's frequency.



Q. Is there a circuit diagram for a transistorized Q-multiplier that can be used with i-fs in the 1400 kHz region?

A. The lead from the Q-multiplier (see figure) to the plate of the mixer stage in the receiver should be shielded. The coil used should have a high Q and, for 1400 to 1450 kHz, should be an iron-core unit having a value of 120 to 130 uH. The resistor tied to the 25k pot will have a resistance of from 3k to 40 kΩ, depending on the transistor used; the value must be obtained experimentally. Try a 5k unit with the HE-3 transistor. Before changing resistors, try various low-voltage dc values. If a 2N1742 transistor is on hand, it will work extremely well in this circuit.



Q. Is there a circuit diagram available for building a code practice oscillator?

A. The code practice oscillator circuit in the figure can be built for approximately $6. This circuit does not require a plate or B-plus supply. It is essential, however, that high impedance headphones be used with the circuit for maximum performance.

Digital Autopatch

- - with touchtone dialer

E.E. Buffington W4VGZ

Burlington NC 27215

Photos by Danny Turner WB6TUG/4

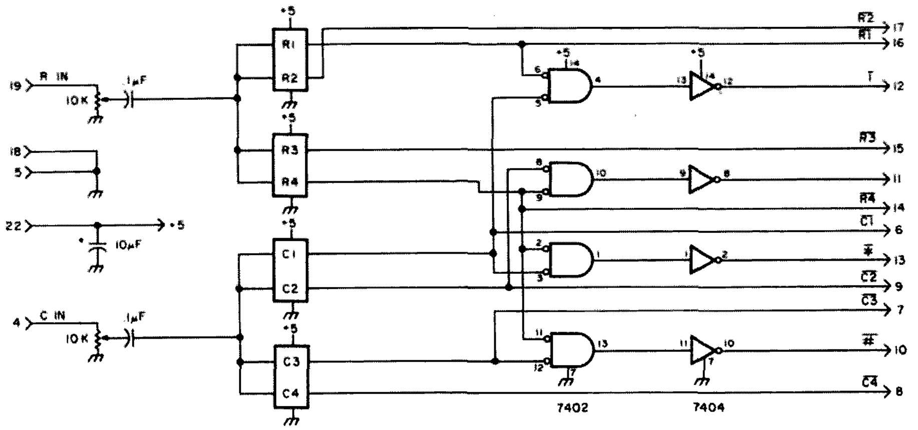

*Fig. 1. Decoder board with NAND gating to supply all rows, all columns, *, #, 1, and 0.*

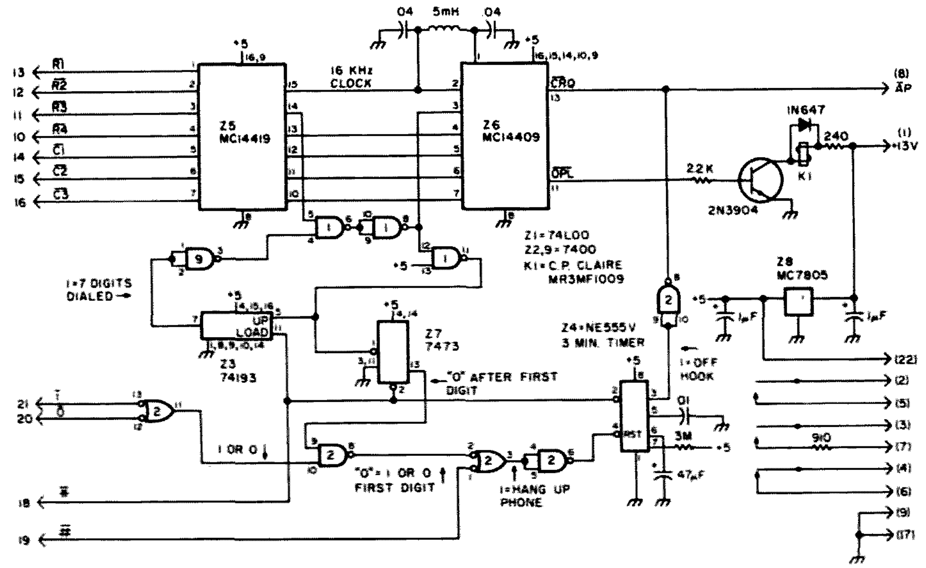

Fig 4. The dialer accepts logic signals from the decoder and dials the phone.

The recent introduction of two new IC chips by Motorola has really opened the door for a practical autopatch for the repeater that does not have access to a touchtone signaled phone line. This article describes all the circuits you need for phone patching.

The MC14419 and MC14409 are the good news items that we have been waiting for. The MC14419 is a 2 of 8 to binary decoder which takes a row-column input, does debouncing, and converts to a 4-bit binary number. The debouncing consists of furnishing a strobe pulse to the MC14409 only after the row-column information has settled. The MC14409 stores this data and dials it out at the proper pulse rate. The storage capacity is 16 numbers and can be read and outpulsed over and over again by using the redial feature. The autopatch described here is in operation on two repeaters presently and is performing just fine.

The Decoder

I designed the decoder around the EXAR XR2567 IC chip because it is a dual decoder and costs only slightly more than a single 567 decoder. The decoder board uses four of these chips to decode the four rows and four columns of the standard 16 button pad. (See Figs. 1 and 2.) There is some "AND" gating done to get (*), (#), (1) and (Ø). These four, plus all rows and columns, are

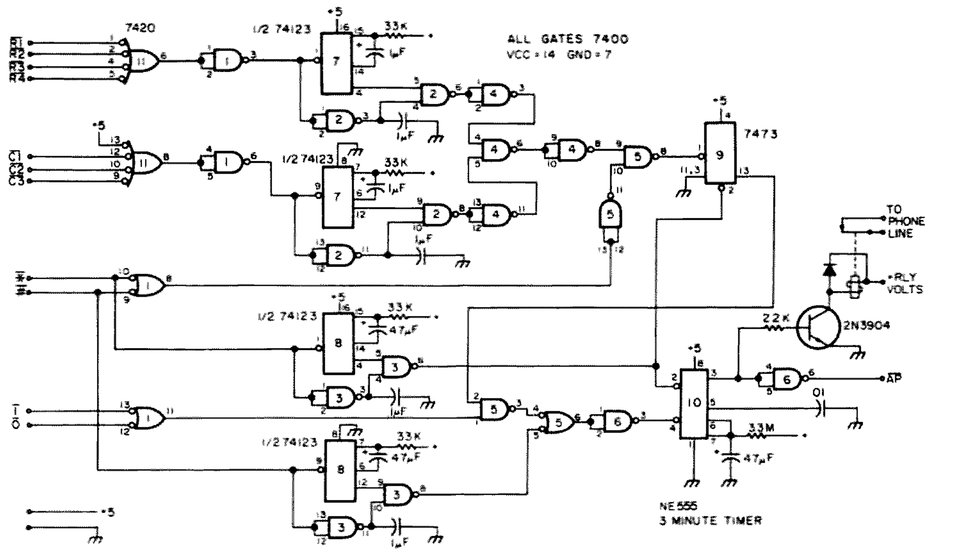

Fig. 7. Control circuit for touchtone signaled phone line.

(Ø) is the first digit, the phone will disconnect."

It was found in the model that some voices would cause a row-column match and keep dialing the phone after the connection was made. This was overcome by limiting the number of digits to 7. The 75192 loads a "1" with (*) and counts to 8, thereafter inhibiting strobe pulses.

The three minute timer will terminate the call after 3 minutes. The call will also terminate with (#) or with (1) or (Ø) as the first digit. The $\overline{AP}$ line is used to turn on the transmitter and the logging tape recorder (third party traffic, you know!).

A fix was also needed to keep voices from "talking up" a dial tone in normal repeater operation. A retriggerable multivibrator (74123) was used to insure that $\overline{*}$ or $\overline{\#}$ must be held low continuously for one second before the output goes low. I don't have a circuit board layout on this feature yet, but the schematic is shown in Fig. 5.

Touchtone Signaled Line Control Circuit

Fig. 7 is the logic for a control system that will initiate the call, start the timer, and provide lockout for (1) or (Ø) as the first digit. The operation of the circuit is pretty straightforward, except for the debounce feature. Begin with (*) going low for one second. This sets the J-K flip-flop ($\overline{Q}$ output goes high) and starts the three minute timer. The output of the timer is inverted and is furnished as a signal to start the tape recorder, make the phone line connection, and keep the transmitter on. If the next digit is a (1) or (Ø), the timer will reset and the phone connection will be broken. The first digit dialed will clear the J-K flip-flop so the next or any subsequent digit can be any digit including (1) and (Ø). A (*) or (#) is not recognized as a digit. The retriggerable multivibrator 74123 is used as a debouncer. The any-row or any-column debouncer is set at 20 milliseconds; the (*) and (#) debouncer is set for 1 second. A logic low must be present for the full time in order to get an output after that time. Any glitching or contact bouncing that takes

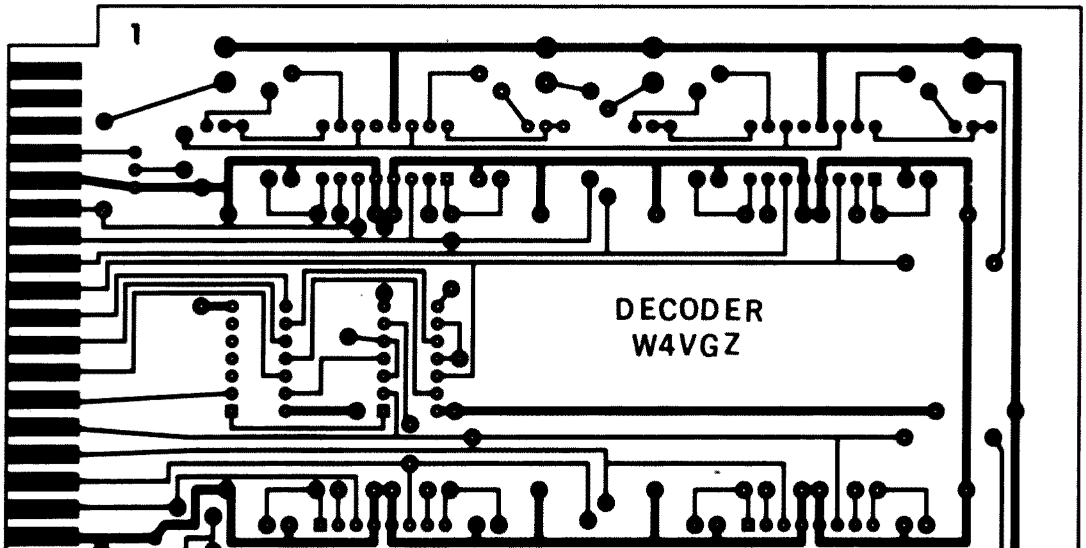

Fig. 8(a). Decoder board.

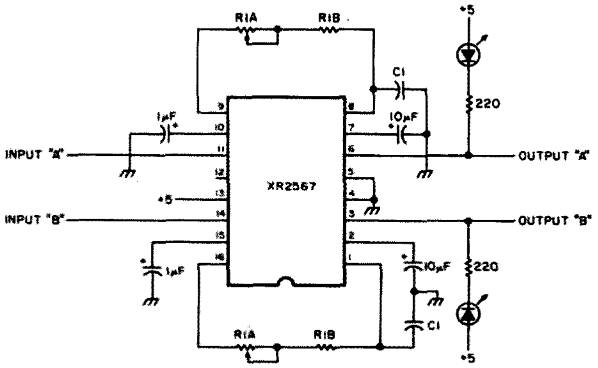

Fig. 2. Dual tone decoder. Four of these decoders with R1 and C1 values from Fig. 3 are used for the complete decoder (Fig. 1).

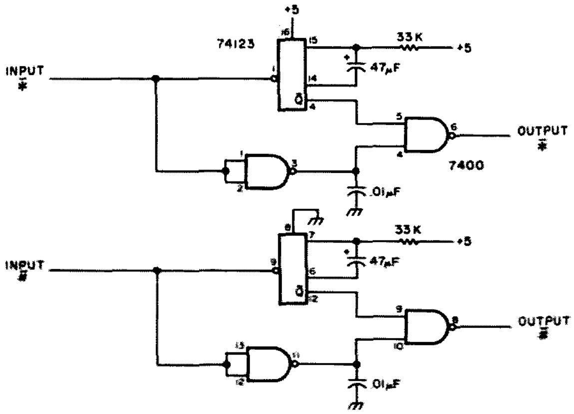

Fig. 5. Dual contact bounce eliminator.

	Freq.	C1	R1 (Nominal)
Row 1	697 Hz	0.1 mF	14.3k
Row 2	770 Hz	0.1 mF	13.0k
Row 3	852 Hz	0.1 mF	11.7k
Row 4	941 Hz	0.1 mF	10.6k
Column 1	1209 Hz	.047 mF	17.6k
Column 2	1336 Hz	.047 mF	16.0k
Column 3	1477 Hz	.047 mF	14.5k
Column 4	1633 Hz	.047 mF	13.0k

Fig. 3. Decoder frequencies and timing resistor and capacitor values.

provided as outputs. The decoders are trimmed to frequency by monitoring pin 9 or 16 of the XR2567 and adjusting the pot for a free-running frequency equal to the desired lock frequency. This is done, by the way, without an input signal. The nominal value of R1 is shown in Fig. 3. The fourth column is not used for autopatching; however, you may find it useful for control of some repeater functions.

The Dialer (Fig. 4)

I decided that I didn't want to pay for someone else's toll calls, so I put in a "fix." This fix makes the logic statement: "If a (1) or

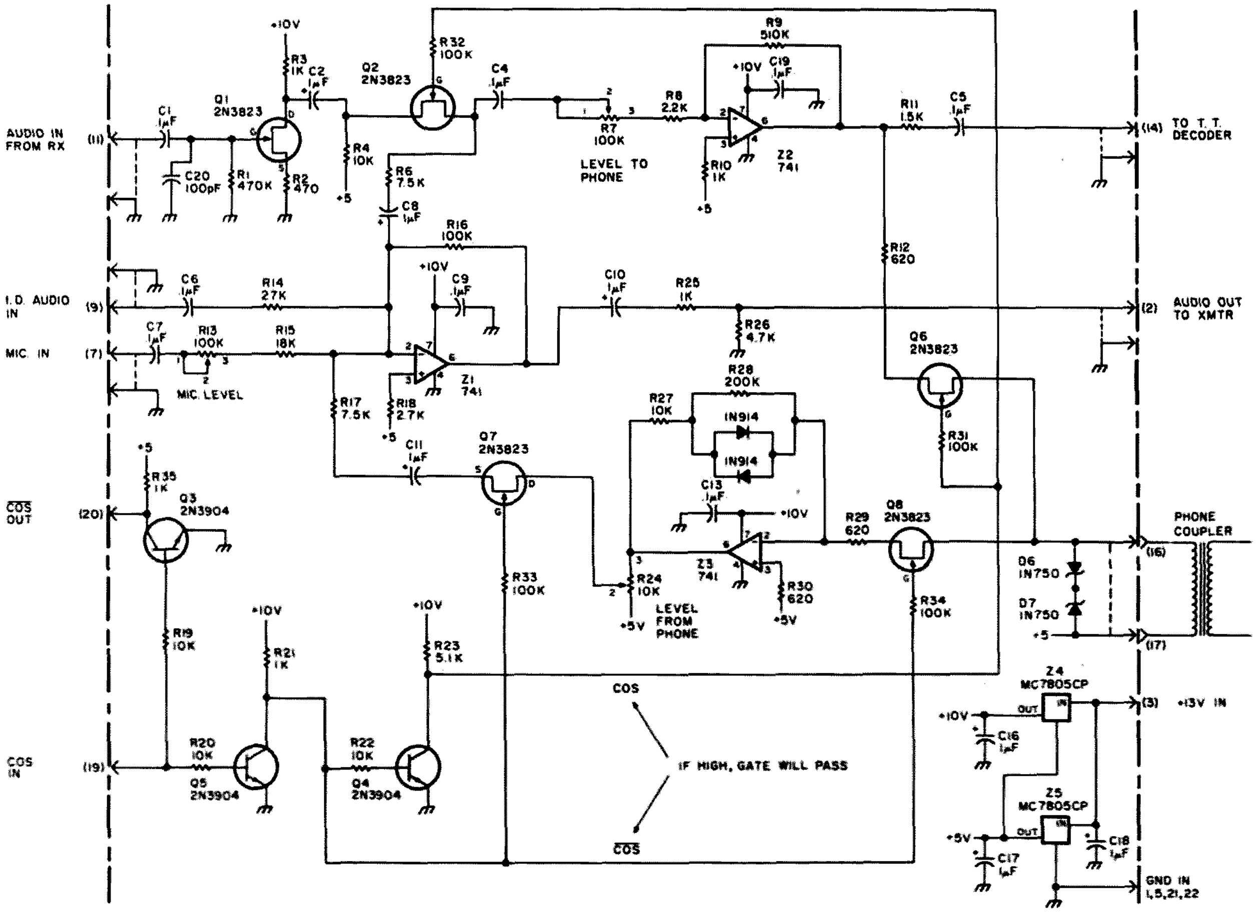

Fig. 6. Audio interface board. R5, Q3 not used. Highest R = 31; highest C = 20.

place before this time is over will retrigger the single shot and extend the time by the single shot period.

Audio Interface

The audio board (Fig. 6) connects the receiver output to the transmitter, phone

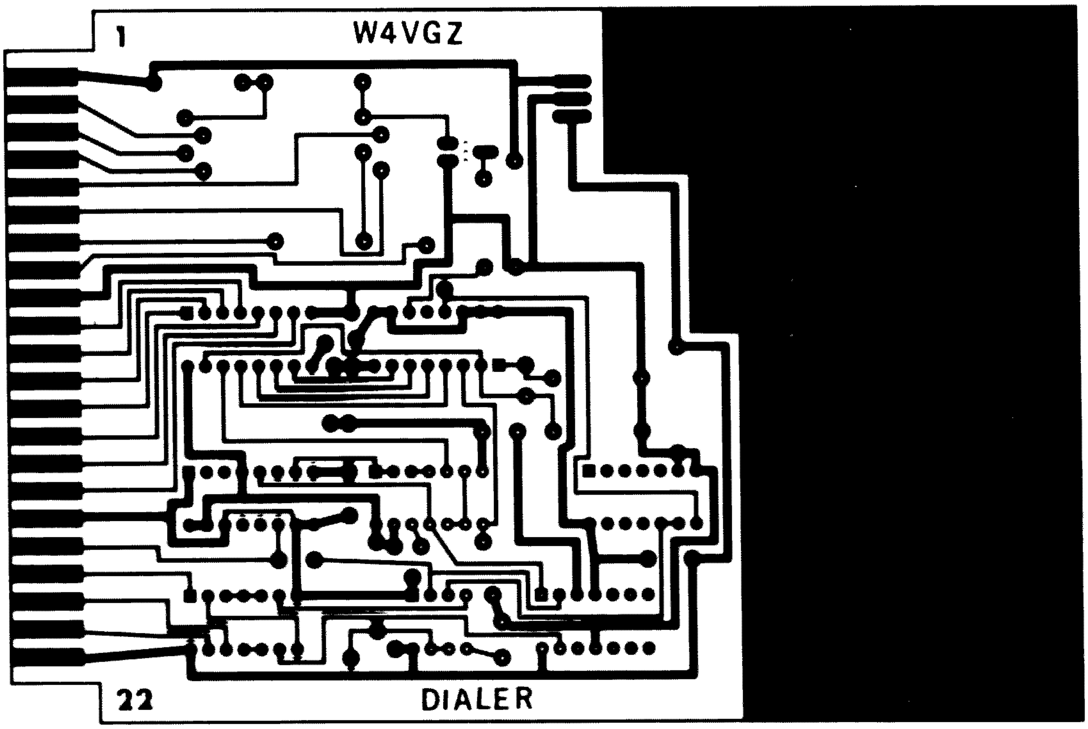

Fig. 9(a). Dialer board.

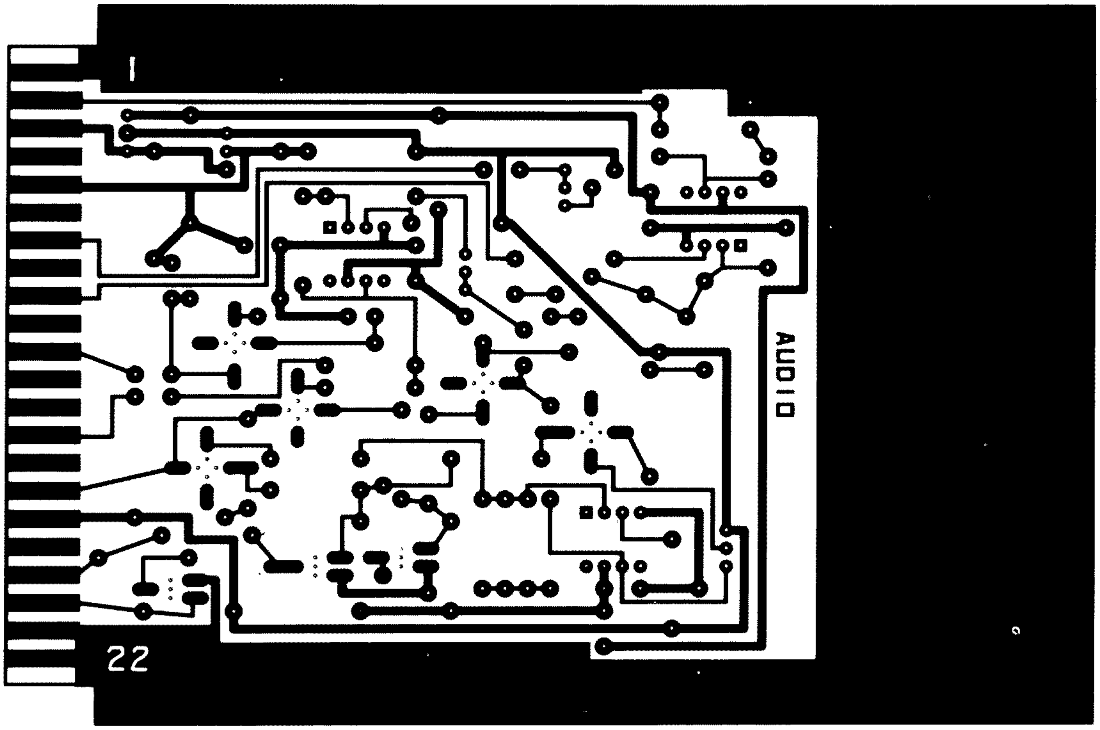

Fig. 10(a). Audio board.

line, and decoder. It has provision for local microphone and ID audio, and has a compression amplifier for boosting the phone line signals. The compression amplifier has high gain for weak signals and less gain for strong signals. All switching is done by FETs. The carrier operated switch (COS) input is active high. If you have touchtone signaled exchange, the audio board, the decoder board, and the additional logic (Fig. 7) are all you need.

O. C. Stafford
427 South Benbow Road
Greensboro NC 27401

Price is $20.00 per set, postpaid.

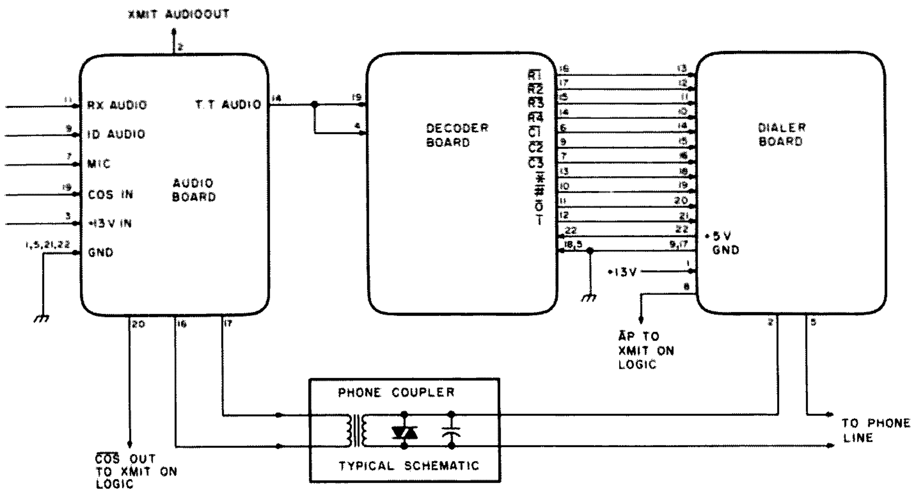

Fig. 11. Overall schematic.

Construction

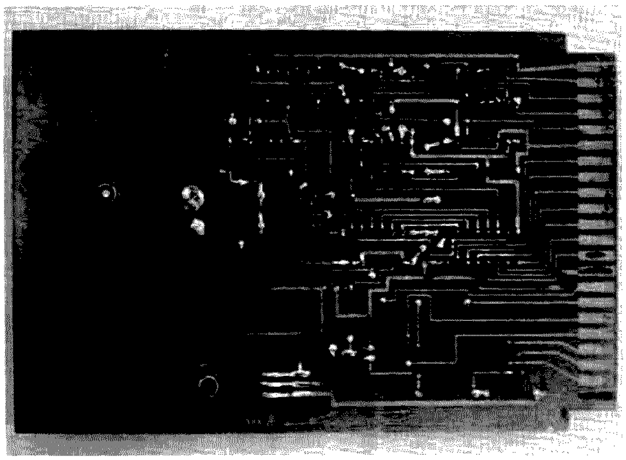
Any local print shop can make the negative (or positive) you need for making your own boards. You can purchase, from Kepro, presensitized boards in the 4 x 6 size. Just follow the directions given in every package of boards and you shouldn't go wrong.

The inductor for the 16 kHz clock oscillator shouldn't be a problem. I have used coils from 3 to 10 millihenries (with the appropriate capacitors) and they worked OK. You can mount the coil on the area used for the 5 volt regulator heat sink. The formula for finding the value of the capacitors is:

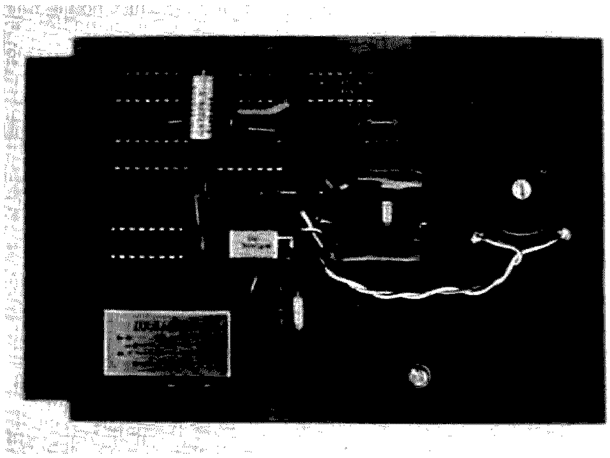
$$C_L\ (\text{uF}) = \frac{2}{10\ L(\text{mH})}$$

Cheapskate Shortcuts

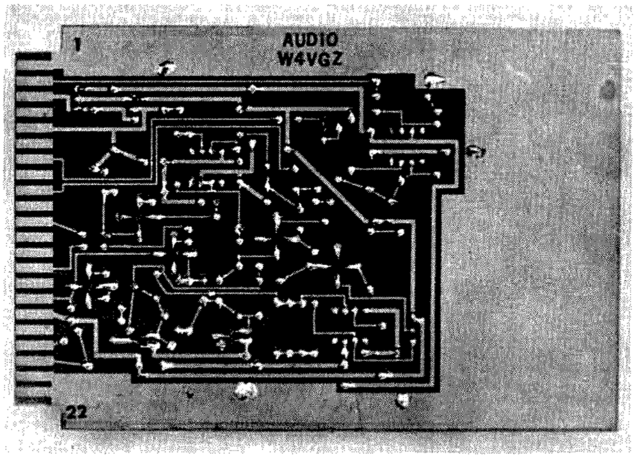
All boards mount in 22-pin card edge connectors. You could solder directly to the fingers and save some



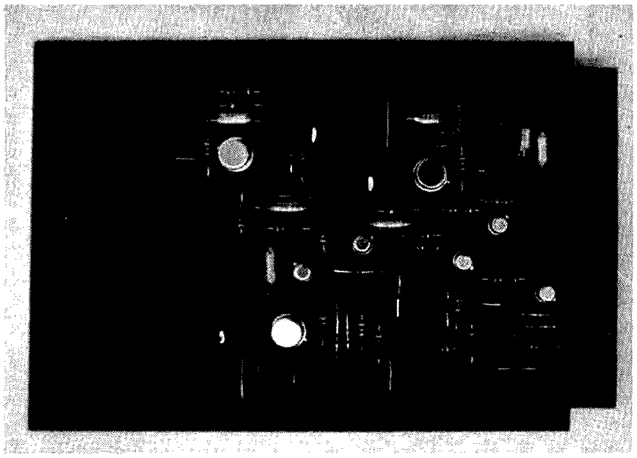
Dialer board, foil side view.



Dialer board, component side view.



Audio board, foil side view.



Audio board, component side view.

money. Fixed value resistors could be used for the audio input on the decoder board to limit the input to less than a quarter of a volt rms or so. The level is not critical at all. You could soldertack a pot to find the value needed for proper frequency and then substitute fixed resistors if you want to save about $15 in pots. Watch out for the orientation of ICs, especially the MC14409. Make sure you don't put them in backwards. Pin 1 on the PC board is square instead of round. You could get by without the LEDs. Just increase the load resistor from 220 Ohms to 1k or so, and put in a strap for the LEDs. A junk box relay could be used (instead of the reed relay specified) and mounted externally to the circuit board; just put in jumpers over to the contact fingers.

Parting Shots

An attempt was made to keep a constant impedance on the phone line between transmit and receive. If there is any problem with the phone company on this, you will have to put in a hybrid coil and take out the FET switch Q6.

One day you might find yourself getting wrong numbers. Check first to determine if the phone company is set up for dual mode signaling on the line. They have a setup so that either dial pulses or touchtone will work. The system used here does not mute the tones, so that both the tone and dial pulses will be present on the line. I have not encountered this personally but have talked to others who have. The circuit shown in Fig. 7 should be used if this is the case.■

Harness the Wind

-- practical hints

The wind bloweth, and the hams want to use it. The articles that I have been perusing are good in theory. In practice they do not work, period. Even the commercial wind electric generators are very disappointing in performance. I know; when I was young I was making a living making those stupid contraptions work. When the power company brought in the wires, I looked for another job.

If you are interested in putting up a wind electric system, follow the outlines of a good theorist, but do the main things he leaves out, which are: You cannot charge a 12 volt battery with a 12 volt generator, the generator being 30 feet in the air, and the battery under cover at ground level. Even the commercial units try to do this. Also, you cannot light a 12 volt bulb with a 12 volt battery over the house wiring. All that you will get is a red light, depending if the battery is fully charged or not. The secret of a successful wind electric system is to have the generator rated at twice the voltage of the lights, to a voltage regulator positioned close to the battery, with the battery one and one third times the voltage of the lights.

At that time I used a six volt system. Thus, a 12 volt generator to a six volt regulator to an eight volt battery. Four batteries were wired in series-parallel. The wiring must be as heavy as you can afford.

Practicality works when the theory leaves much to be desired. The alternators of today would greatly increase the efficiency of the device, as the wind does not blow steadily. Any questions? ■

EDITORIAL BY WAYNE GREEN

LEARNING CODE

While on the one hand I'm a bit concerned over the code courses that are proliferating . . . thus inevitably touting some newcomers away from the *73* cassette series . . . on the other hand I'm both surprised and delighted to note that none of the competitors seems to have yet grasped the basic concept of how code is learned and what the true significance is of the plateau in learning.

In every objective test of the effectiveness of code courses, the *73* series is at least twice as fast as the next closest course. How can that be?

Let's take a moment to consider just what it is we are trying to do when we learn the code. The usual way of starting the process is to enter the data in the mind, which enables you to translate a di-dah into the letter A, etc. First you memorize the dots and dashes for all of the letters, numbers, and punctuation. Then you listen to them sent slowly and mentally look up each dot-dash pattern in your mind, comparing it with the table you have memorized. When you get a match, your mind tells you what the letter is and you write it down.

Then you gradually speed up this process until you are operating at the fastest speed the mind can handle on a conscious level . . . which means a code speed of around ten words per minute, give or take a little . . . and in no case as high as thirteen (why do you think the scoundrels set the speed at 13?). No matter how hard you try, your mind can't go faster looking up each code group . . . hence the plateau.

But obviously something does happen, for we have people who can copy code at close to 100 words per minute . . . so there is a way past the plateau. What happens is that the code sound patterns . . . not the dots and dashes themselves . . . are automatically translated by the subconscious mind and the character comes to mind seemingly from nowhere. This is why good CW operators can sit and talk with you and then turn around and typewrite the copy they've been hearing while they were talking. The copy had nothing at all to do with the conscious mind processes . . . it was all on a subconscious level. It is this complete retraining which produces the plateau.

The plateau is a long one because there is a long battle in your mind, with the conscious trying to translate the dots and dashes . . . and not being able to keep up . . . while the subconscious is quietly trying to get through and tell you it's got perfect copy . . . shut up already with the other process. This battle defeats all too many prospective hams.

But is this whole battle really necessary? Why should we even bother to go through the conscious mind process at all, since it is of no long range benefit and in fact is about the worst possible way to tackle the project? Tradition . . . as Teyve lauded in Fiddler. Tradition is still with us and bogging down tens of thousands of poor souls who are trapped by it. Tradition keeps the ARRL pursuing this system . . . and sucking hundreds of ham clubs into it with the ARRL tapes. The *Ham Radio* tapes stick rigidly to the ARRL tradition. And so do most of the rest of them.

So how can code be learned without the old process? By starting directly with the training of the subconscious mind . . . starting out above the speed the conscious mind can handle. I'll bet that a newcomer to Morse code can learn the code almost as easily at 25 words per minute as he can at five words per. He has to learn to recognize the sound pattern of the letters rather than the dots and dashes. Even at 50 words per minute, it doesn't take long before you can pick out the letter "E". Then you'll begin spotting the "I"s and so forth. If you let your mind go blank and listen to fast code, you'll start having the letter E jump right out at you with only a few minutes practice . . . and gradually the other letters. You then have to train your fingers to type them as they come . . . or to put them on your mental blackboard and copy them in your head.

There is a limit to how fast we can spell out words, even with the submind doing the work . . . but I don't know what it is. I suspect that the high speed CW fans are copying words rather than letters . . . particularly when they get up around 100 wpm. This is more like speaking a foreign language . . . a lot like it. You have to use a foreign language quite a bit and continue to use it to keep it functioning on a subconscious level where you don't have to translate everything both on receive and send. Eventually you get so you "think" in the new language . . . and this is the way of high speed CW.

A good Morse code course will start the beginner out with each character being set at the end desired speed . . . 13 wpm. Then, as the subconscious gets trained, the spaces between the characters are closed . . . but the sound *patterns* are kept the same. We're trying to recognize these sound patterns, and if we continually change them by changing code speed, we are essentially forcing the brain to start all over again. This is okay if you have the time and a world of patience.

Code instructors from clubs run into hard core cases where people are unable to learn even the whole alphabet. Their conscious mind just won't make the grade. I suggest that these people may well be able to do just fine on a subconscious training program. Send code to them from the *73* 13 wpm cassette and ask them to listen first for the E . . . then the I . . . etc.

The subconscious mind can do fantastic things. Many of the brilliant mathematical skills are done subconsciously. In fact, there have been many cases of people who were barely able to function on the conscious level, but who could do cube roots subconsciously. They didn't have any idea of how it happened . . . the answers just came to them from nowhere.

During my years working as a psychological counselor, I used a direct approach to the subconscious to avoid the protection against mind repairs put up by the conscious mind. The subconscious mind is right there all the time and extremely easy to contact and use, once you get the hang of it. You're using it all the time . . . trying to remember a name . . . which "comes to you" a bit later. Or trying to solve a problem and a solution "occurs to you" later, etc.

Starting right out to learn the code with a 13 word per minute tape is a shock . . . it staggers the conscious mind . . . heck, everyone knows you can't learn the code that way. Nuts . . . you can start out at 20 words per minute if you want, and you'll be able to copy it perfectly in a fraction of the time of the chap who starts out at two . . . five . . . seven . . . ten . . . plateau . . . plateau . . . twelve . . . thirteen . . . grunt . . . and slowly upwards.

I have no doubt that loyal ARRL fans will continue to make life miserable for prospective Novices and Generals with the traditional code system as epitomized by the ARRL tapes and W1AW transmissions . . . even though it goes against everything we know about how the brain works. In the meantime, those who have lucked onto the *73* cassettes will have a tremendous advantage . . . and they will mostly end up enjoying code instead of hating it.

It is difficult to love anything

which causes you a whole lot of pain . . . and learning the code via the traditional method is a big pain in the . . . ah . . . mind. No wonder so few amateurs go on to stick to the CW bands! Code can be easy and fun, if it's taught right. It can be a skill to be proud of, and not a dark and unpleasant stumbling block which you have to overcome to get a ham ticket. Which way are you making it for the new hams?

AVUNCULAR ADVICE ASKED

You are probably not unaware that the Novice training courses started by ham clubs around the country are generating thousands of Novices and that the drop in the number of hams has been turned around. A good deal of the recent growth of readership of *73* has been due to these Novices subscribing . . . mostly as a result of their use of the *73* Morse code tapes and the *73 Novice Class Study Guide*.

Perhaps you, as an old-timer, have some advice for these newcomers to our hobby. You may have an antenna that you think they should know about . . . perhaps there is a rig that you think is great and you'd like to recommend . . . maybe you have some modifications which would help them . . . or you might like to suggest books or magazines which would benefit them.

You can reach these newcomers to hamming via the pages of *73* . . . with a letter to the editor or perhaps a short article. It's easy to write for *73* . . . just be sure to type it double-spaced so we can fix up them grammar or speling errors. Give these chaps a helping hand through *73*.

SIGNS OF DECAY

A letter from John Askew W4AMK suggests that every member of the ARRL hierarchy be required to read C. Northcote Parkinson's book, *Parkinson's Law*. He refers in particular to chapter six, which seems to almost have been written with the ARRL directly in mind.

The gist of the chapter is that the building of a well-planned headquarters is achieved only by institutions on the point of collapse. Parkinson has done his homework well on this, and gives voluminous proof to support his contention.

As far as I know, the members of the League were not consulted about the use of nearly $1 million for additions to the headquarters building. Here we are at a time when more and more amateurs are becoming seriously concerned over the approaching debacle at Geneva with the ITU and WARC . . . and money that could have gone for some ham ambassadors to visit third world countries and garner support for amateur radio is being spent on newer, bigger, and better offices. Just think how far a million dollars would go toward protecting amateur radio!

Parkinson points out that a vigorous institution spends its time getting things done and pays little attention to its surroundings. A visit to the ARRL's enormous building, with its chrome furniture and pile rugs, can be contrasted with the utilitarian *73* offices, with old desks and a strictly make-do atmosphere. We have over 60 people working at *73*, jammed into a 250-year-old house and having the time of their lives.

It isn't until an institution is running down that it spends its time erecting an edifice . . . and this turns out to be its monument to the better days of the past.

Here we are with the U.S. government ready to take away half of our 75 meter phone band and the whole 40 meter phone band as their official proposal at WARC . . . and the ARRL is spending most of the money it has gotten from us over the years on administrative space to provide comfortable offices for even more assistants to the assistants.

You may put me down as being overly critical of the League only if you can come up with an alternate proposal which will help protect amateur frequencies and include spending $800,000-plus for more office space in Newington. I don't think anyone has more input on what is really going on than I do . . . and I see no cause for complacency.

SELLING THE SALESMAN

I'm a real sucker for anything new . . . and Chuck Martin WA1KPS, down at Tufts Radio, knows it. I blundered into his store the other day to drop off some of our newly published books . . . *The New Hobby Computers* . . . and the store was so packed with hams that I had trouble finding a spot to park! Chuck was up on the roof putting up more antennas.

Once he was back on the ground and we'd eyeballed for a while, I mentioned that my IC-230 had one lamp out . . . maybe he could fix it. Oh, pshaw, he said (or words to that effect), "Why are you driving around with something as out-of-date as that? You should be using the latest in digitally-synthesized ham gear." That sounded good to me, I admitted . . . and before I knew what was happening, my IC-230 was out and a brand new IC-245 was in. I sure hope he gets a good price for the 230 for me.

The IC-245 is quite a step ahead. No longer do I have to be bewildered over the 15 kHz splinter channels. I had 'em all on the IC-230, but I never knew which was which, and when I visited another area I just had to fly blind. With the 245 I get a readout of the receive frequency when receiving and the transmitting frequency when transmitting. I can program the darned thing for 600 kHz splits, for 1 MHz splits . . . or any other splits that repeaters may come up with. It knows all about transmitting high in the 147 band and transmitting low in the 146 band, but this can be defeated for the upside downers.

After some months with the 700A Kenwood at the home shack, I have been accustomed to tuning in the receiver with a regular tuning dial . . . and liking it. They sure don't hide any repeaters from me any more! The 245 tunes the dial in 5 kHz synthesized jumps. This makes it so I can tune up and down the band, checking active repeaters as I go. If I want to break any of them, my transmitter is right on channel automatically. No more trying to remember if the upper/lower switch is in the right position . . . no more using a switch to go from the 146 segment to the 147 . . . and the whole package isn't any larger than my old IC-230.

Chuck was so slick about it that I never did notice when I had agreed to take the thing . . . he just assumed that I would, and the next thing I knew I was driving away programming the new rig as I went. I did have to run a separate power wire for it to keep the synthesizer powered. When you turn the rig off with your ignition switch, you then have to reprogram the synthesizer again — and that gets old. You can use a transistor radio battery for the keep-alive current, if you are too lazy to run the extra wire.

And that isn't all. The audio from the 245 sounds a whole lot better, both on receive and transmit. Mr. Inoue, you've done it again!

SPIES NEEDED

If you are anything like me, once you get your hands on a tunable two meter receiver, you set about making a list of every repeater you can hear . . . and every simplex net. You look for the inputs of strange repeaters and get the call letters of all that have any identification . . . and listen a lot on the channels of repeaters which are obviously being kept sub rosa. In other words, you are curious and a snoop.

If you are cut from the same bolt, how about making a copy of your list of repeaters and sending it in so we can be sure to keep our repeater list updated? We'll update the *Repeater Atlas* and publish late changes in *73*.

We want to keep the *Atlas* as up to date as possible as a help to traveling hams . . . so do your part . . . be sneaky and send us your secret agent reports . . . send them to Fearless Leader, *73 Magazine*, Peterborough NH 03458. That goes for DX hams, too, by the way.

HAMS VS CB

For some reason I seem to get a lot of newspaper clippings from *73* readers which involve CB radio. I have two things to say about this . . . first, please keep it up. I appreciate every clipping you can send me about CB (good or bad) . . . about ham radio . . . or about any of my other not too secret interests such as Jordan, submarines, UFOs, microcomputers, and things like that.

A recent clipping sent in by good friend K7EML was an ad in a newspaper for a 100 Watt CB amplifier (not to be used on CB) for $120. This points up a question . . . is the FCC serious about CB linears or not? Another dealer ran an ad for a linear in a magazine and got a phone call from Charlie saying in effect to go ahead and sell 'em, but don't advertise, because that would force them to put on the heat.

Even though about 80% of the new hams are coming via the CB ranks, there is a question in my mind as to whether what goes on there is really any of our business. We don't mix with the mess on the marine channels . . . or the terrible things on taxi and police channels. CBers have no patent on bad language over the radio. CB is another separate service, and I feel like we're butting into a family problem . . . someone else's family . . . when we get involved with CB.

Since I do write a weekly newspaper column for CBers, I have a personal interest in CB . . . not a whole lot . . . I don't get involved with any base station baloney or rag chewing with base stations. My column is mostly devoted to explaining the facts of life to CBers and pointing out the advantages of getting into hamming . . . what skip is and why . . . what the sunspots are going to actually do to them . . . stuff like that.

WAYNE TALKS

I'll be on the program at Atlanta on June 18-19th . . . come armed with questions. I often forget to cover things people want to know about, so make notes and bring 'em. I'll also be talking at Seattle July 29th, if you're in the vicinity. Both of these are going to be superb conventions, so I hope you'll be there and say hello.

COMPUTERIZED POLICE

More and more police departments are following the lead of the Las Vegas PD and installing computer terminals in the road cars. This permits them to check on car licenses automatically and find out if the car is wanted anywhere in the country (or if there are any warrants out on the registered owner). The whole business takes about 10 seconds, versus the pre-computer time period of 10 minutes or more.

The police officers were against the innovation, but when they found out how useful it was, opinion changed. It didn't help when one officer got involved with using the terminal while driving and wrecked the car, the terminal, and almost himself. Most of the officers now pay more attention to the rules about stopping before using their terminals.

The system provides automated dispatching of the patrol cars and automated report writing, in addition to the computer data base on people and car licenses.

In Washington DC, this has made it possible to check on parking tickets quickly and put one of the "Denver" yellow boots on the wheel of a car which has outstanding tickets against it. The boot locks on and keeps the car from being moved until the owner settles up on the unpaid parking tickets.

HAM COMPUTERISTS

I've been asked to give a talk on the ham uses of computers at the 1977 World Altair Conference in Albuquerque (May 3-7). Although I've heard from a few hams who have been using microcomputers, there are a lot of you out there who haven't written. I'd appreciate getting as much information as possible on any applications you may have developed.

LETTERS

PART 97.112

Federal Communications Commission
Washington DC 20554

This is a request for the FCC to consider modification of FCC Rules and Regulations, Part 97.3(b).

I propose that the following words be deleted from the part mentioned above: "and without pecuniary or business interest."

This particular phrase, while questionable as to its intended implications, is virtually unenforceable, the subject of wasted controversy, and overtaken by events that continually transpire on repeater autopatch facilities.

It is agreed that Part 97.112 is valid and needed regulation; however, the broad and ambiguous wording of Part 97.3(b) is detrimental to the amateur service because of the unnecessary confusion created by it.

While the primary reason for requesting this change is to realize the full advantages of repeater autopatch technology, the parallel case is operation of the Class D Citizens Band under Part 95. We have virtually no difference between a Class D operator ordering a pizza via his CB radio or an amateur doing the same via a repeater autopatch – except that the former is authorized while the latter is steeped in controversy. The question of avoiding telephone company tariffs is moot, because in the case of the CB operator the telephone is avoided completely, while the autopatch is providing an income for the phone services.

Your expeditious consideration of this subject is solicited and a copy of any germane request for comment or rule and order is hereby requested.

William J. Howard
FPO San Francisco

HAM SCHOLARS

The Foundation for Amateur Radio, Inc., a nonprofit organization with its headquarters in Washington, D.C., announces its intent to award four scholarships for the academic year 1977-78. All amateurs, wherever resident in the U.S. and holding an FCC license of at least General class, can compete for one or more of the awards if they plan a full-time course of studies beyond high school.

The John W. Gore Scholarship pays $750. Applicants must intend to pursue a career in electronics or a related science and have completed at least one year in an accredited college or university toward a baccalaureate or higher degree. Preference will be given to residents of the District of Columbia, Maryland, and northern Virginia.

The Richard G. Chichester Scholarship also pays $750. Applicants must be members of the ARRL and be sponsored by an ARRL-affiliated club. There is no restriction on the course of study, but applicants must be enrolled in or have been accepted by an accredited university or college and intend to seek a baccalaureate degree. Preference will be given to residents of Ohio, Kentucky, Indiana, Illinois, the District of Columbia, Maryland, and northern Virginia.

The Edwin S. Van Deusen Scholarship pays $250. Applicants must have been accepted or enrolled in an accredited 2-year technical school and intend to seek an Associate degree in a science-related area. Area preference is the same as the Gore Scholarship.

The Radio Club of America Scholarship also pays $250. There is no restriction on the course of study, but applicants must be enrolled in or have been accepted by an accredited university, college, or technical school and intend to seek at least an Associate degree. There is no area of preference.

Application forms can be requested from FAR Scholarships, 8101 Hampden Lane, Bethesda, Maryland 20014. Requests must be postmarked prior to June 1, 1977.

The Foundation is devoted exclusively to promoting the interest of amateur radio and to scientific, literary, and educational pursuits that advance the purposes of amateur radio.

Amateur Radio, Inc.
Washington DC

TV 3320

The following is a rundown on my experiences with the TV Typewriter 3320 designed by Jeff Roloff and sold by Mini Micro Mart. Possibly you haven't built this model TVT, but maybe my experiences will help you in shooting trouble with the one that you are building. This happens to be the third TVT that I have built, and each time the various models develop new problems, so this time I am going to put into writing the problems that I ran into. I feel sorry for the fellow 40 miles from nowhere who runs into some of these problems.

First off, the delivery of the kit was somewhat late. Apparently the supplier of the PC board lost the prints and didn't make delivery on time. So really this was not the fault of Mini Micro Mart. I would like to make mention that when I called Mini Micro Mart, they at least answered the phone, and at one time accepted a collect call from me. I completed the assembly on Christmas Eve, getting all of the bugs worked out at that time. It prints a very nice copy.

One of the things that I would highly recommend you use is the timing chain waveforms if you have a scope but don't have a counter. Most scopes will count the crystal frequency and then the prints indicate the divide by n as you go through the circuits or ICs. If you lay out the exact number of waveforms on the scope for the input frequency (let's say 10 square waves to start with for 10 mm of deflection), then if the timing chain indicates the next test point is half the frequency, you will come up with 5 square waves for 10 mm of deflection (which says that the next IC has divided by 2).

As you go through the complete timing chain, you will note this takes place. Also, any offsets will be apparent. Also, if you take a ruler and extend the various waveforms back up the sheet, you will see where they compare to some previous waveform that should indicate whether the circuit is working correctly or appears to have trouble. As you continue down the chain, you will discover where the scale changes, and you will have to recalibrate the timebase (frequency of scope) setting of the scope. This will give you a new setting to start with, and then you can continue from there. Frequencies in the timing chain of Mr. Roloff's TVT all come out correctly. I also found that the timing chain in SWTP TVT #1 came out OK; I built two of their units.

Getting back to the TVT 3320: I found some printing errors on the schematics. In Fig. 16 showing timing, the output of IC #2 pin 9 is L or 7920 cycles, pin 8 is M or 3960 cycles, and pin 11 is N or 1980 cycles. All of these terminals and readings are correct. These frequencies go to IC #14, and this is where the first error occurs. The first error shown is L going to pin 13 – really it's N. Pin 9 of 14 shows N going there, and it's really L (the final addition of the frequencies comes out OK, but if you attempt to check the input to IC #14, it can throw you). L1 comes out 7920, which is correct from the timing chain. I might mention at this time that L1 and L1 bar are the same frequency-wise but have a phase reversal; that is, the wave train on the scope will be right side up for L1 and upside down for L1 bar.

Also at this point, I would like to mention that the waveforms should be all of the same height. I had a condition where I had 5 mm of height going into the IC but less than 1 mm of height coming out of it (due to a small piece of wire from a piece of steel wool that had accidentally gotten onto the bench). A defective IC following this loading effect can also cause loss of power in the drive.

Another schematic error is in Fig. 16 on timing. IC #17 pin 3 is shown as going to Fig. 18 (next line blanking), IC #41 pin 11. Instead, IC #17 pin 3 goes to IC #12 pin 11 and then IC #12 pin 10 goes to IC #26 pin 5. So IC #2 is used in place of IC #41 as this particular inverter. The final frequency and inversion is correct, but if you are tracing trouble with a scope, you can be talking to yourself.

At this point, we were feeding a composite video signal into the video display. The problem was that we were getting broken and distorted letters and numerals. The consistent thing was that any letter trouble was always the same as if it were hardwired, which indicated that the trouble was not a spike or frequency problem. The trouble appeared as if maybe a solder ball might be underneath some socket (which I used throughout).

At this point, I used a piece of wire from the five volt supply with a 330 Ohm resistor in series, and touched terminals 17, 18, 19, 20, 21, and 22. This will give a letter display on the screen as follows: 17 will give an AT's in some circuits, but in this circuit it gives an A; 18 terminal will give a A when an AT's appears before, but if an A appears, then a B will appear; 19 will give a D on the full screen (same as above); 20 will give an H; 21 will give a series of P; and 22 will give a blank. You can tie any or all of these input terminals together, and get any letter or numeral in the ASCII code. With this type of input, I proved that the trouble was either in the 2513 character generator or the 74166 shift register. The only letter that was distorted was the A, as on both outputs the above letters were all OK.

I now duplicated the circuit of the 2513 and 74166 on my proto board and fed the output into the transistor buffer that fed the video display. Lo and behold, all of the letters and numerals that I could generate were alright.

Now the problem was to find the cause of the trouble. At this point, I would like to make the comment that I have found that you can short the inputs and outputs of the 2513 and the 2519 and the 74166 and not get into any trouble.

So I started by shorting the outputs of the 2513 character generator, which is also the input to the 74166 shift register. As I am going along, I discover that I can duplicate my exact condition by shorting pins 6 and 7 of the character generator (which says I have duplicated the trouble). This bears out the above assumption that it must be hard-wired and possibly a solder short. After looking very closely, I conclude that the trouble has to be under the 2513 character generator.

Well, this is a 24-pin socket soldered to a double-sided board, and God had better be with you if you are going to unsolder and remove the socket. After very careful consideration, I decided that unsoldering was not the answer. Rather, I took a small screwdriver and pried the plastic holder up, leaving the terminals soldered into place. It came off very easily, and nothing broke, believe it or not.

Now I checked terminals 6 and 7 with a continuity meter again and the

short was still there. Getting the magnifier into operation, I could not find a solder glob of any size. I did find an eyelet just barely touching a piece of foil. This was corrected with a very sharp knife, and the short disappeared on continuity. The black plastic form for the 2513 socket was gently pushed back on the soldered terminals and then taped into place, and everything looked real good. I fired up the TVT and it worked beautifully — giving me the excellent Christmas Eve present of a workable TVT, which I believe was worth all the trouble I went through.

NITTY GRITTY

I am a CB to ham convert. I came across a deal on a SSB CB radio in Sept. '76 that I could not pass up. It was installed in my vehicle and I listened (not having anything to say) on various AM channels for about two weeks. I found for the most part that it was crowded with people who had nothing to say.

The next step was to try upper and lower SSB. I did and could not make sense out of what I heard on the channels. Somewhere along the line, I found lower 16 and intelligible conversation. It didn't even resemble the nonsense on AM.

I found a "home" for listening on lower 16, but I did not understand a lot of things, i.e., QRT, QSY, QRX, go down ten, Apache 45, Ex-Calibre 99, etc. I found no one used their FCC callsigns. Anyone not conforming to procedure (using the 10 code, AM talk, using callsigns) was quickly ridiculed by the "knowledgeable" frequency cops. I once heard a guy call, "CQ 11 meters — CQ 11 meters," to which he received a chewing out about not understanding radio. (Only now do I realize that the poor guy was probably only a ham with at least a General ticket and more radio knowledge and ability than anyone on 16.)

One way or another, I came in contact with one of the SSB club members, went to a meeting, and joined the club (needed one of those funny callsigns). I learned what the codes meant and messed up my radio with all the "trickstuff" a good SSBer has.

I was OK for about three months, until I finally realized that I was running as illegally as possible, going nowhere, calling myself an 11 meter radio operator (never a CBer) and being just plain frustrated.

Several members of the club have ham radios they run on 11 meters only (what a waste). I saw their radios and knew I had to have one, but it would never transmit on 11 meters.

I dropped out of SSB, sold my radio, passed my Novice written back in January, bought a radio and am awaiting my ticket.

Now the nitty gritty!

I turned on my radio tonight to monitor the Novice bands. I tuned 40 meters and found a QSO where the guys had a good fist and were a little faster than I could copy (good practice). All of a sudden, right on the frequency of a QSO, some lid began tuning up and calling CQ.

This is not the first time I heard this, but tonight it made me sick and reminded me of CB.

I did not try to put down CB, but ham is heads above. It makes me sad.

Louis C. Berry
Simi Valley CA

P.S. You do not have to plead with CBers to upgrade to ham. It takes some longer than others, but it is a natural transition (if they will spend as much time learning the code as they do bad-mouthing it).

What more can we say? — Ed.

WORD FOR WORD

I hope that you will print this letter word for word in *73*.

To begin with, I am sorry that I have ever spent a cent for *73 Magazine*. I feel that the magazine spends a lot of space on slandering — that's right — slandering the ARRL and its publication *QST*. If you use all of the space that you waste doing this on amateur radio issues, you might find that radio would benefit from it.

For example, in February, 1977, *73*, we find Wayne Green attacking the League on the WARC. Nowhere in his editorial did he offer any concrete evidence on what the ARRL is doing. Unless he can back up malicious statements like "... but I know they are far more interested in spending $800,000 on a new wing for the HQ building than trying to protect our bands." Wow! A magazine that would print such a thing as this with not one single word of supporting evidence (i.e., names, dates, places, or even quotes from the WARC) must be a really poor publication. I don't know how many hams have benefited from the HQ services, but without the nightly (and daily) code practice sessions, I am sure that there are many hams out there who would not have gotten their General (and above) tickets. (By the way, I don't see *73 Magazine* operating a service like this to the amateur radio community.)

Come to think of it, and correct me if I am wrong, outside of publications of various kinds, I don't see where *73* does anything at all, save sit around and condemn the ARRL. It is easy to sit in a chair and say what the ARRL is doing and what you *think* they should do. After all, you're not the one who is doing anything, except perhaps misconstruing and taking out of context everything in a League publication. You aren't in the position where decisions have to be made, and sitting in a chair with a good hindsight is a lot easier than having to make the decisions.

Then I read articles like "Talk About DX — WOW!" in hopes of finding out some new research in propagation and see how much of a waste of space it is. Or then there is "CB Can Do Some Things Better." Could we have these spaces filled with something worthwhile about amateur radio? (Before the CB world comes down on me, I have a CB and a license for it, but if I wanted to know something about CB, I would go to a CB publication.)

Then, the mere fact that you print some of the letters you do — do you select as many anti-League letters as you can? Letters using great and outstanding examples such as HAL discontinued a keyer or that one of the thousands of electronics companies has a PEP wattmeter and then saying something like,"ARRL is really on top of things," just shows how foolish these readers are. I hope that if they miss anything in the field they are in for a career, that their credibility will never again be trusted. (By the way, if I may use the same unsupported logic from these people, if *73* has ever printed an ad for Trigger, which I have also had trouble with, I hope that we realize that it is not as interested in the amateur radio world as it is in securing advertisers to increase its greedy income — see, I can speculate too — but, in doing so, I have condemned everyone who writes or works for *73*. Are you letter writers really using your heads?)

I am not saying that *73* is all bad — I have seen good things. But some changes have to be made. For instance, when the term "dBm" is used in the "Novice Q & A" column, it ought to have a definition. Many beginners, as well as old-timers, may not understand such things, as the only place I have seen it is in the commercial broadcasting.

Secondly, if you, or any of the letters you publish, condemn the ARRL (or any other organization), do it — but don't do it without any proof. I have seen no proof of any kind that is substantial enough to say the ARRL is doing more for themselves than ham radio or that they are behind the times.

The space you waste on condemning the ARRL and then the fact that you don't seem to be doing anything about it really gives me a negative attitude on the whole magazine. In fact, it is hard to trust the credibility of any article in a magazine whose editors spend their time blatantly cursing everything else. If you are against something and can show substantial evidence, then I might withdraw my ARRL membership. But as it stands now, you only help support my belief that the ARRL is the finest organization available to amateurs. If you want to put the ARRL down, quit talking and get up your own teams of lobbyists and go to the WARC. Prove yourself. I am only sorry that readers often tend to listen to writers of poor editorials. If everybody agreed with your philosophies, then we would all read *73* and the FCC would be able to pass any regulation they wanted to and amateur radio would be the loser.

I hope that you will publish this entire letter, as I feel that it has a lot to say. I am sure that a lot of readers will condemn me for this letter, but if they cannot prove their points by showing good evidence that I am wrong, then they only prove my point further.

David O. Wever WB2CQX
Greenwich NY

GOOD BUDDY

Received my March issue of *73* today. While I am a very recent subscriber to your publication, I must rate it tops in its field. No offense intended to *QST* or *CQ* magazines, as I have subscribed to both of them in bygone years.

First off, I was a ham long before the 11 meter Citizens Band was even thought of. I used to work the 11 meter ham band, as I am almost certain that Wayne Green did (judging from his call letters). The thing that irks me, and probably most hams who did not rise from the ranks of the CBers, is the very fact that we were chased out of the 11 meter band, in order that it could be handed to a group, on the proverbial "silver platter," and used in the same manner in which the hams had been using it. Except, no examination requirements were involved. This provided many would-be hams with a cheap and effortless way to enjoy hamming. This probably was not the intent of the FCC. But, what else could the FCC expect? After all, a person who did not possess enough intelligence to plug in an electric coffeepot could obtain a Class D Citizens Band license, with no questions asked. That is, provided he or she met the age requirements and could produce the license fee. Pretty cheap price to pay for hobby-type communications privileges.

Many articles which are published in *73* seem to promote the idea of ham clubs going all out to recruit prospective hams from the CB ranks. This seems ridiculous to me. If these CBers had desired to become hams, they would have done so in the first place, the same as thousands of us did in years past. I am employed as an electronics technician for a railroad, and have a shop in a terminal. Many railroaders, who are also CBers, come into my shop, asking if I can furnish them with railroad frequency crystals for their CB rigs. The railroad radios operate on approximately 1-3/4 meter FM. These same people refer to themselves as radio operators (not as electrical appliance users). When mention is made to them that they

may be interested in becoming a ham, the first question is, "What have I gotta do to get a ham license?" When the ham licensing requirements are explained to them, the immediate response is, "too much trouble." One young man accepted my offer of assistance, and is now a very devoted amateur radio operator. So, it is possible to make a radio operator out of a CBer.

I was amused by the letter from Jim Cullen WA2ENR, in which he asks, "Where would hams be without CB?" I wonder if Jim believes that all hams rose from the ranks of the CBers. For his information, there were hams long before CB was even thought of. As a matter of fact, there have been hams since the very beginning of radio, as we know it today.

There are many complaints of jamming, tuning up on net frequency while nets are in session, profanity — the list could go on and on. This is not good for ham radio in general. It seems as though this sort of thing has become more prevalent within the last decade. One cannot help but wonder if these offenders did not rise from the CB ranks.

Anyone reading this letter may draw the conclusion that I am down on the Citizens Band radio service. That conclusion would be far from true. However, I am down on the inconsiderate people who use this band strictly for hobby purposes. CB was intended for small businesses and individuals who had need for an economical two-way radio service for business use. Many persons who invested money in CB equipment for business use soon learned that CB had been taken over almost entirely by "The Good Buddy Set," who can talk all day and say nothing.

During the 25 years that I have been a licensed ham, I have tutored many people to hamdom. I have lost count of the number. This was not done through a recruiting program. Anyone who expressed a desire to become a ham received my encouragement, cooperation, and assistance. If we go out and start a full scale recruiting program from the CB ranks, we might well end up with the 80, 40, 20, 15, 10, 6, and 2 meter Citizens Bands. There is strength in numbers, but quality should also be given some consideration. Lest we forget, hams must demonstrate their ability as radio operators before they are permitted on the air. Let's keep it that way. Let us not permit people to become licensed amateurs simply because they have enough money to purchase a ham rig. The ham license has already been cheapened enough.

Verle D. Francis W0SZF
McCook NE

220-420 CB?

This letter is regarding the use of 225-420 MHz by the government and the letter by Merrill See W8BGZ, of Kalamazoo MI. Although I am not a government agent who can give you an official report, I can give some informal information as a bit of background.

For the past 8 years I have been a Ground Radio Maintenance Technician (that is, a radio repairman) for the US Air Force. A major portion of my job in that time has been with radios that operate in the 225-400 MHz frequency range. These radios are used mainly for Air Traffic Control (ATC) of military aircraft. They are also used extensively for other information to pilots, and for command and control. These uses mean that these radios are used continuously on a 24-hour, 365-day-a-year basis. The only thing I've ever run across that is used more is CB's channel 19, and the VHF ATC radios used by both the military and civilian airports. To open this frequency range up to Citizens Band type use would require that not the military but the Congress of the United States and the budgetary bodies of many foreign countries allocate a very large sum of money to scrap a working worldwide system and design something new to replace it with. Moving all operations to the VHF ATC frequencies would not work, because of the increase in congestion and because some places use more spectrum space than is available in the entire VHF ATC band (which in itself is larger than the entire 2-30 MHz HF range).

The 406-420 MHz band is also used worldwide by the military. Although it doesn't carry as much traffic as the 225-400 MHz band, it is used daily for ground mobile radio service. Moving this would also be an expensive proposition.

The preceding is not meant to be a complete report; it is just my observations of one user that I have worked with on three continents.

As an answer to question #3, "Careful evaluation of the priorities of the needs of the United States Citizens," I personally think our needs are being served fairly well for an important purpose on these frequencies. They are not very visible to the public, but they are used extensively for a public service.

If anyone still wishes to convert these frequency allocations to a direct citizens' use, I recommend that they practice by removing their local police, fire, and other government services from the frequencies now used by those services.

Ronald E. Seibel
Edwards CA

NEW DIMENSIONS

My three-year-old son is one of the estimated 335,000 Americans who cannot hear any speech; he is able to hear or feel sounds below 800 Hz only with much amplification. Unlike the many blind who are able to participate in our hobby, he and another estimated 13,000,000 hearing-impaired persons have, by the nature of our early emphasis on audio communications, been excluded.

We do have one thing in common — the desire to communicate. FCC code regulations would seem to limit licensing, but my son Kurt can recognize most of the code alphabet and will certainly be able to copy as soon as he can write (although much of the chatter on our CW bands is trite and hardly a learning experience).

In the past few years, relatively expensive telephone TTY equipment has been offered to the deaf. The slow data rate utilized by most limits use to local calls, but mass production should bring the cost down and thus make for more availability to amateurs. I am sure you can see the possibility of a "deaf net."

A new, exciting communications mode has been made available to us through the efforts of the Public Broadcasting Service and FCC order RM-2616. If you have ever tried watching TV with the sound off, perhaps the Muppet Show, you soon realized that something is missing. PBS has developed a system by which captions can be sent on the previously unused scan line 21.

Persons desiring captions would use a simple decoding device. Mass availability of this device, estimated to cost around one hundred dollars commercially (probably less through our surplus channels), would also give us easy access to any TV for TTY, computer, or code conversion uses.

The basic system is described in graphic form in Figure 17, Section 73.699, of the television standards.

Line 21 would start with the normal blanking pulse and program color bursts. This would be followed by seven cycles of an approximately 0.503 MHz signal to synchronize the decoder clock, two cycles of spacing, and then 17 cycles to transmit two 7 bit plus parity ASCII characters. Line 21 of the next field would be used to send a 9 bit pseudo-random framing code to indicate where the two characters should be located. Each eighth frame would consist of a pulse to set the zero crossing bias point.

While this system has the disadvantage of slow speed (52.5 characters per second or 630 5-letter words per minute), it has the advantages of being CMOS-compatible (cheap), not sending unless space data (the pseudo-random code) is provided, and requiring minimal onboard memory.

It should be obvious that dropping the clock run-in, slowing the clock rate to one telephone-compatible, and adding memory would allow the same system to be used for other purposes.

A letter to your local PBS station might speed adoption of this system, and give us yet another equipment dimension.

Our efforts to introduce the deaf to our newer modes of communication might well add a new dimension to our hobby.

Wichita KS

LEVY REPLIES

I would like to take a moment to correct a gross misrepresentation of the facts presented in Mr. Briggs' letter in a recent issue of *73*. It can be expected that there may arise misunderstandings in business dealings, but there is no excuse for distortions of the magnitude represented there.

Mr. Briggs purchased a prescaler kit in February, 1975. Nothing was heard from him until the summer of 1976, over a year later, with a complaint about low sensitivity. A suggestion regarding the possibility of shorted input protection diodes was made, and a set of diodes was sent, free of charge, for him to try. Failing in that, I advised that the cost of a new scaler chip, if that were the problem, would be about $35.00. He subsequently returned the unit, advising that the diodes did not cure the problem. He had mounted the scaler board in a box, from which it was removed, and examined. The difficulty was in fact a defective chip. There was a delay of several weeks prior to the completion of the repair, for various reasons. It was decided to make the repair at no charge. The chip was replaced, the unit reinstalled in Mr. Briggs' enclosure, tested (despite what Mr. Briggs may say), and the unit and his check returned. A nasty letter containing the same allegations as in his letter to *73* arrived a couple of weeks later.

If Mr. Briggs had taken the trouble to open his box and examine the scaler prior to making his allegation, he would have noticed that the chip had on it a date code subsequent to his original purchase date, which is pretty good evidence that it was in fact replaced. The unit was tested prior to being returned with an in-calibration $2300 signal generator; why it did not function for Mr. Briggs is merely conjecture on my part. However, any suggestions to remedy the problem were cut short by his letters.

There are no other manufacturers that I know of who do service on kits eighteen months after sale for free; Mr. Briggs might like to try that with a large manufacturer and see what happens. In any event, there is no excuse for accusations of "sunshine" repair at any price when they are simply not true. Mr. Briggs would do well to check his facts next time.

CB TO 10M

I just read your article in the *73* Holiday edition, 1976, about the possible changes of CB equipment to a usable 10 meter system. This sounds great to me. I am a frustrated CBer who is working on a ham license.

I fell in love with 2 meters during my recent exposure to The Salvation Army work in Guatemala, where I was responsible for establishing an emergency radio system. We used 2 meter equipment with a repeater on top of a mountain for 200 mile coverage of the area. Now I just need that extra push to get at least a Tech level.

But back to the article: This is something that needs to be followed up with some organized system. There sure are a lot of people with closets like mine, used to store CB equip-

ment. It just got too noisy!

Keep up the good work. Could you put in some novice (simple) projects for beginners? I'm not quite an electronics engineer yet — but working on it!

Fred Musgrave
Baltimore MD

We have a series of CB to 10m conversions coming along, Fred. With the current depressed prices of 23 channel equipment, the time is right to obtain a rig and get in on the fun on 10. See you there. — Ed.

BRIEFS BOOSTER

The recently expanded "Briefs" section is great. Warren Elly is to be commended for his efforts in searching through countless club newsletters to keep us all up-to-date on interesting news. I have seen to it that *73* has been added to the mailing list of *Spark Gap* from the Two Rivers Amateur Radio Club.

After reading the Editorials, Briefs, Be My Guest, Looking West, the FCC news (with and without commentary), and the vast quantity of readers' letters each month, I find myself very well informed on what is happening in ham radio. The rest of the magazine seems like a free bonus!

Also like the corrections letters grouped together rather than scattered as they were in the past.

Don't change a thing (except for the better).

Joseph R. Nelis, Jr. K3JZD
Trafford PA

THE RASCALS

I find myself puzzled at the logic of many of the amateurs who write letters to *73*. So many complain that ARRL is not representative of the amateur fraternity and that *QST* simply does not fill the bill as a "ham rag," so — as so many have written — they refuse to join the League until *QST* becomes the kind of magazine they want.

In view of the fact that ARRL is a membership organization, and that *QST* is its journal, the way to *least* affect the nature of the organization or the content of its journal is to resign or not join. That leaves it with members like me who like the journal as it is now published — in fact, it gives us almost total sway in keeping it much as it is now. Quitting such an organization and railing at it from the outside is much akin to telling the baseball team you'll quit and take your football home if they don't let you be the quarterback, when every other member of the team has a football in his hot little hand. Obviously, your leaving makes it even easier for the rest to do things without regard to your wishes.

If you honestly want to see change — in what is clearly an important spokesman for amateur radio (perhaps in a way you dislike) — don't quit. Join, and get your buddies to do the same. Then "vote the rascals out," electing directors who espouse your point of view and who will move to make *QST* what you want. I'll still be there trying to buck you, but I don't even have to try while you're outside. Obviously, the League must, legally and morally, pay more attention to my wishes than to yours. After all, I am a member.

Don't holler at me in the pages of *73* (to which I am also a subscriber). Join the League and take me on where you can influence the things you dislike.

David G. Boyd WA9GBW
Waukegan IL

You could not have summed the editorial position of 73 more concisely, Dave. For your information, most of the hams at 73 are League members. — Ed.

A WORLD OF GOOD

First of all, thanks to you and your fine staff at *73 Magazine*. You've done it again. Through an unfortunate mistake, I lost my faith in Heath Electronics, and with your help all is going great guns again. They *do* stand behind whatever they sell . . . even to the point of refund. So, here is to Heath, keep up the good work.

Another unbelievable first for a "biggie" — I wrote KLM Electronics concerning technical advice on their PA10-160BL 2 meter amplifier, and guess who I got an answer from? Mr. Leland M. Farrer wrote me personally and in simple terms, so a lid like myself could understand. He explained my problem and how to correct it. This exchange of information took less than ten days. Now we know why Mr. Farrer is president of KLM; let me say they are fine folks to do business with!

Just one last word about you and *73 Magazine* — please, please, keep up the good work. So many amateurs become discouraged too easily with one thing or another and give up this fine hobby. But, with your help, the editors' "feedback" section, and reporting good things along with the bad, it does us all a world of good. Please accept my personal thanks for making my hobby much more fun!

David L. Martin WB9UKJ
Evansville IN

MISUNDERSTOOD

I would like to come to the defense of a group of misunderstood people.

After reading in your magazine about "steely-eyed" examiners, and such comments that would make someone think of the FCC as an enemy of sorts, I cannot hold my silence.

Having taken my General, Advanced, and Extra class exams, all from the Boston office, or outlying examination points, I have never gotten an unkind word, and, as a matter of fact, have found that these people really extend themselves to help you, and make you feel as relaxed as they possibly can.

They won't break any rules for anyone, but we really couldn't have it any other way, could we?

Your books are great, and I could not have gotten my Extra without their help.

E.L. Melanson W1HOB
Montville ME

A SWIFT KICK

The controversy about I/O is still going on, in spite of the handwriting on the wall, huh? Please do me a favor and eliminate all that wasted space devoted to DX, super basic electronics, CW, 6800 micros, RTTY, history, etc. I am really not interested in any of that. (Did I miss anyone's toes?) Oh, the argument is that there are magazines devoted to computers, and you should leave it to them? How about saving the space you waste on contests? "You know who" has many, many pages of contest data every month. Leave it to them.

Seriously, a year ago, I could have written a 10 cent article (at your rates) about everything I knew about computers. Now (the XYL will never forgive you) I have George Morrow's 8080 and I am slowly putting a system together. Who knows? Another year and I may learn some programming.

By the way, how about asking those wonderful, talented Fergusons if they could rewrite that OS (Ahhh! beautiful system) for 8080 with no monitor. You could probably find a half page to print the dump.

As far as leaving I/O to computer magazines, I am a charter subscriber to *KB* (same as in the radio area, only 1 mag) but *KB* is not really the place to print Oscar locator programs or (dare we hope?) Don Alexander's program for winning RTTY contests without even being there.

I have only one complaint. Why didn't you give me a swift kick at an RCB meeting many years ago, when I didn't give you my $37 for a lifer?

Al Klein W2PMX
Miller Place NY

SOFTPEDALING

I really have enjoyed *73* the last three years and am looking forward to the next 36 issues.

One thing, though, for *myself* and perhaps many other hams — I hope you soft-pedal the I/O section. There are so many areas of amateur radio, e.g., slow scan, ATV, Oscar, and many others that we haven't touched yet, that there is no time for I/O.

The amateurs who have been at it for years and have explored all the other facets of the hobby perhaps go for it, but I changed to *73* because it had more projects for the *average* ham, with more down-to-earth projects. Don't spoil it all.

73 is put together nicely, and the advertisers I have dealt with, such as James and Poly Paks, have given good service. I don't always agree with your ideas, but that's a free press.

D.S. May WB8ATR
Van Wert OH

Sorry 'bout that, Don. If you check through past issues of 73, I think you will see as many "general" articles as always, including the I/O section. Computers are to some as RTTY is to others, and should be considered a special interest area of ham radio. I don't think you would knock the RTTY content of 73, so lay off those who are interested in computers — everyone has his thing! — Ed.

1635 UTE

Recently, while monitoring 3725, I began to note a strange popping coming over the speaker. At first I did not pay too much attention to it, as QRM and QRN are quite commonplace on all the bands. As the intensity increased, I suddenly realized that my antenna was being bombarded by a form of radiation. The longer I sat there, the more intense it got. I began to get a little shook, having kept track of the latest Chinese nuclear explosion for a while after, due in part to its size and the cloud it had created. I called the local police to find out who monitors the environment in this area. I was told they couldn't help, as they had no contact with any group or individual who did. Then I called the local air base and the operator put me in contact with base environment. I was told that their reading was normal. I couldn't believe it, so I called downtown to the American Atomics Corporation to see if they would take a reading for me. Their man had already gone home for the day, but an individual gave me the phone number of a local civil defense official here in Tucson. His secretary told me she would try to locate him and ask that he call me, and he called in about ten minutes. I explained to him what was happening over my receiver and he said that he would take a few readings and call me back.

He called back and notified me that I had nothing to worry about, as they could not detect anything more than normal. About 30 minutes went by before Les Heru W7WIT called and gave me another number to call. This is what I learned. Some parts of the universe are studied more than others, and our area, the Crab Nebula, is studied rather extensively — in the constellation of Taurus the Bull.

Recently, a strong emission of gamma radiation was detected in a tight band of wavelengths coming from the Crab Nebula pulsar. This radiation is caused by positrons (a subatomic particle the size of electrons but opposite charge) and electrons destroying themselves.

Some of this radiation may have been what I heard coming over my speaker. I really can't say without more research, but as the Chinese radioactive cloud created by their latest endeavor was out-of-phase with my QTH at the time, it is unlikely that it was the cause.

If some of the hams who read your magazine have also heard this, I would like very much to hear from them as to time of day and date and approximate intensity. What I heard came over the speaker 19 Jan. '77 and seemed to peak out at 1635 UTE. The sound is somewhat like popcorn being popped or, for those of you who have heard radiation in a geiger counter, the sound is the same.

Bill Morris WB7ETZ
Tucson AZ

Are you sure it wasn't a noisy 12AU7, Bill? — Ed.

POTSHOTS

In the March '77 "Letters" column, Bob Billson WA2TXY, regarding the 1976 Hudson Division Convention, complained that "he could not afford that type of a hamfest and that it cost $4.00 to get into the flea market." In addition, he felt it chased CBers away. Well, Bob, I've got some news for you — the convention (not hamfest) registration cost was $4.00, which included all forums, exhibits, flea market, and hotel activities. Forums take a lot of time and effort, besides expense, to put together. They are a platform for exchanges of ideas and a place to learn. Anyone can wander around a flea market all day — it's only one part of a convention.

Over a hundred of your fellow hams spent 12 months of spare time and time off to put it all together, not to mention considerable personal expense, and we had to buy our own $4.00 tickets. We don't deserve cute potshots by people who don't take the time to find out what it's all about. The hotel was sold out . . . and over one third of the registrants were CBers who thought more about the hobby than you did. Many of them requested training and license information. If you can find us a site and workers to put on a hamfest for three to four thousand people at no cost, please let me know. By the way, have you ever attended a convention?

As for cheap shots from the Editor regarding nonprofit organizations, you should be interested to know that we donated $1,000 to the ARRL for WARC preparations and $500 to AMSAT. So go the profits. We welcome requests for funds to be used by worthwhile national and division projects. See you in '78.

Henry Wener WB2ALW
East Hills NY

OKALOOSA

The time has come to take my favorite editor to task with respect to the article "CB Can Do Some Things Better" by David Norman in the March, 1977, issue of *73*.

I would like to correct some implications in the "Public Service" section with respect to Hurricane Eloise. First, we hams did not fold our tents and fade into the sunset when the repeater went down. We knew for a long time that our split site repeater on Okaloosa Island was vulnerable to high water. Therefore, our emergency plans did not include a great dependence on WR4ABZ. (As a matter of interest, the repeater was off the air for less than 24 hours.) Our operations shifted immediately to 52 and 94 simplex. Even when the antennas were lost at the Civil Defense Center (primarily due to the wind loading of the large CB antenna on the mast), WB4VJP, the Civil Defense Station, was back on the air in minutes with an emergency antenna.

As far as "the odds of having two units equipped with 2 meter rigs in both those places at that particular time," there was at least one instance during Eloise where a heart attack victim was provided rapid ambulance service because there were 2 meter rigs at both the emergency shelter and the hospital.

In addition to the local communications efforts, local hams handled hundreds of pieces of traffic from all over the country with relation to Hurricane Eloise, a function which cannot be supplied by CBers.

I do not mean to downgrade the effort put forward by the local CBers (which was outstanding), but to dismiss the effort of over 40 local hams with "and then the lights went out all over town" is, to say the least, misleading.

You would have been surprised, and pleased, at the number of hams that showed up with HTs, battery packs, mobiles and home stations with emergency power, and spent many hours in public service during Eloise. Further details on Hurricane Eloise can be found in the February, 1976, issue of (excuse me) *QST*.

Please keep up your usually good editorial work with *73*.

S.M. Allen K4JEM
President
Playground Amateur Radio Club
Fort Walton Beach FL

NUTS!

I haven't had any gripes with your magazine until now.

I am speaking about the article in the March issue, "CB Can Do Some Things Better."

That article should be in a CB magazine. If a person wants to read about CB, just pick up one of the tons of CB mags on the market. I want to read about stories pertaining to ham radio. If you ask me, the article had no place in *73*.

Not taking anything from *73*. It's still a great magazine.

John Kotras WB9UIL
Milwaukee WI

Nuts! We have had several letters like yours concerning the CB contents in 73. I find it hard to believe that hams are still affected by the '60s CB image. Personally, I became a believer this winter when, had it not been for a CB radio, I would have spent several cold hours on the shoulder with a broken fan belt. No, John, we are not becoming a CB magazine, but 73 definitely feels that CB has its place when it comes to public service. I really wonder if you've ever listened lately, John, or is your reaction to the article purely emotional? — Ed.

KEEP ON FIGHTING

I am currently awaiting my Technician license and am interested in 2m FM. I would also like to take this opportunity to congratulate you on an extremely fine magazine. I have recently had 2 letters from the ARRL wanting me to join. Hi hi. Who are they trying to kid? Keep on fighting them and the FCC. Speaking of the FCC, I had passed my Tech exam on November 12, 1976, but still no license. I see no reason for an over 12 week wait for it. They did not even reply to a letter I sent over 3 weeks ago concerning this. All this government nonsense has got to stop, but I see no solution myself.

Finally, I would like to commend International Crystal for their prompt and friendly service in processing a recent order, not to mention your own in sending me the back issues I requested. Also thanks to John King W9KZO for his patience in getting me started in ham radio.

Steve Royer
Greenville IL

500 MILS

Re: "Logical Storage for Logic," March issue.

Enjoyed the article very much, as is typical of your articles. A couple of points/hints:

1. The technique adapts readily to CMOS by the simple expedient of laying a sheet of aluminum foil over the styrofoam. For best results, bond it with glue to keep it from tearing as parts are inserted or removed. This keeps the device pins shorted, preventing static buildup, which is the major problem in CMOS storage. (Always be careful not to touch the pins when handling the devices. An easy way to extract them is to use a plastic alignment tool to pry the parts out.)

2. Conductive foam solves the whole problem. This is what commercial bulk users use (among other things). It is available in reasonable quantities from distributors or bulk IC users, who often throw it out after the parts have been disposed of.

3. Spacing between pin rows is almost always 300, 400, or 600 mils, never the 500 mils stated.

San Jose CA

CUSTOMER SERVICE

This letter is about an unusual company, Godbout Electronics. Last May I bought their 8 Amp 12 volt power supply kit. In October, when I finally got around to putting it together, it drove me crazy trying to figure out why it would only produce 300 mA before shutting down. A letter to Godbout brought suggestions from Kevin Fisher in their service department. More pulled hair and no solution. Another letter and a reply with a new pair of pass transistors and an offer to fix it free. I could not find the problem, so off to the post office with my 300 mA supply. I enclosed a check for return shipping. The supply returned with the check. Thanks, Godbout, for your assistance. Thanks for being a company providing outstanding customer service.

Ross Weber WA0SHA
Killeen TX

PONIES?

By gosh — I've sure heard about the lousy service for some outfit named Trigger, but let me tell you the other end — the business end of the rifle — Bullet Electronics of Dallas sure gives service to their customers. I ordered one of their kits on Feb. 7th, sending a personal check in payment. They received it on Feb. 12th, shipped on Feb. 14th, and I got it on Feb. 18th. How's that for real service?

Now if we could only convince Uncle Sam to stop using ponies — and — well — I can always dream, can't I?

Bob McCormick K4FRX
Columbia SC

A GIFT HORSE?

I have heard a lot of on-the-air criticism about Docket 21033, but those who criticize should ask themselves, am I, or am I not, mature and responsible enough to operate? Yes, there is the possibility of another CB-type bedlam situation developing, but the amateurs I know and associate with are mature enough to handle this relaxation of rules and expansion of privileges. For those who are against Docket 21033, I feel you don't realize that you are looking a gift horse in the mouth and, by rejecting the docket, I feel that you are saying that you are an irresponsible person unable to accept the additional responsibility the FCC is willing to give us. I am willing and able to accept it, are you?

Bill Fulcher W4AST/K4RTA
Hendersonville TN

For the uninitiated, 21033 is the "Repeater Docket" that would, among other things, allow HF repeaters. See Jan. 77 Briefs. — Ed.

HATS OFF

Let me tell you about the "GOOD GUYS." I have been a ham for about 15 years, and have been buying equipment for just as long. In all of this time, I have not found a dealer that I trusted 100%, that is, until Electronic Distributors, in Muskegon, Mich. Some time ago I called them and spoke to Carl. At this point I ordered 2 Kenwood TR-7400As. Right from the start I was told the truth! I was told that the rigs were back ordered, and that I might have to wait 4 to 6

weeks. I sent in a check for a deposit and asked that they ship them C.O.D. Some time later, the active filters came, but no radios. I called; Carl told me that they were shipped 3 weeks before my call. He told me to please give it a few more days and then call back. Well, a few days later the radios came and in good shape. My hat is off to Carl and all the boys at Electronic Distributors. Keep up the good work — they will be getting more (all) of my business!

Keep up the good work!

Midland Park NJ

RECOVERY

I would like to congratulate the members of the Birmingham Amateur Radio Club who participated actively in advertising the fact that some amateur equipment was stolen last December from the Instructional Resources Center of the University of Alabama in Birmingham. This equipment was to be installed in our ham shack. The equipment was a Yaesu FL2000B linear amplifier and two Yaesu digital readout devices, as well as an antenna.

Thanks to the Birmingham Amateur Radio Club, in cooperation with the University of Alabama in Birmingham Radio Club, the equipment was retrieved by the University Police and the culprit will be prosecuted.

Robert M. Ervin WB4VNH
Instructional Resources Librarian
The University of Alabama
Birmingham AL

THE I/O DEBATE

I really like the articles on amateur radio. I will cast my lot with those who say keep the I/O portion to an absolute minimum or else *73* will lose its spot as one great amateur publication. I know there is a lot of interrelated theory, but if you broaden the scope of your magazine too much you will lose the amateur radio buff. Personally, I could care less on what makes a computer tick or how to build or program one. *73* can either be a good amateur publication or a good computer publication — but not both. Somewhere it will cross that dividing line and just fade into a blur of images.

Paul Overdier WBØODK
Westminster CO

BIRDSHOT

I only wish I had subscribed to *73* years earlier! It seems you should start a column devoted entirely to Trigger Electronics, Inc. Up until last month, when I inherited a year's back issues of *73*, I gave Trigger the benefit of the doubt *and* my money. I have suddenly realized that my three or four polite letters to Trigger were like using birdshot on a rhinoceros, and I will have to develop stronger weapons. My thanks to your "Letters" column and WBØPTM (June '76) for the ammunition. Wish me luck. Meanwhile, I have sent for *your* code tapes to begin my long-awaited start in hamming (which has been waiting since May '76 for code tapes from Trigger). I am looking forward to your sensible code approach. Much thanks for an alternative to the ARRL method, which I hear "ain't so hot."

Keep up the good work, and count me in on your side.

Sam Prepelka
Pittsburgh PA

BUILT-IN STATIC

Can anyone top this for a code course on records?

I have a set of five 78 rpm records put out by the "Victor Talking Machine Company in collaboration with the Marconi Institute" in 1918. These recordings are all in the old spark gap mode and progress from the basics to 20 words per minute. Boy, talk about weird-sounding code. The last record has built-in static to teach operators to pick the code out of the QRN. Imagine the task those brasspounders had in those days, picking manmade static out of nature's.

This course was put out to train World War I Signal Corps operators, but the cover says, "commercial students and amateurs may, through these records, become competent operators at home or in camp." So hams had recorded code courses almost 60 years ago.

Elmer W. Hill W8RFB
Wakefield MI

EXTRA CLASS

I had found a note in my 21 wpm code tape that asked for some comments as to the value of the practice tape in preparing for my Extra Class.

I first started out with the 14 wpm and, after copying about 70% of it, I started with the 21 wpm. Both tapes are excellent practice, because when copying tapes of mixed groups, you have no time to think about what is next and it starts to become automatic in a sense.

The FCC has changed the written exam, so you cannot memorize the license manual and pass the test. Some of the questions on my written were right out of the blue.

Cliff Riley K9ZPN
Fort Wayne IN

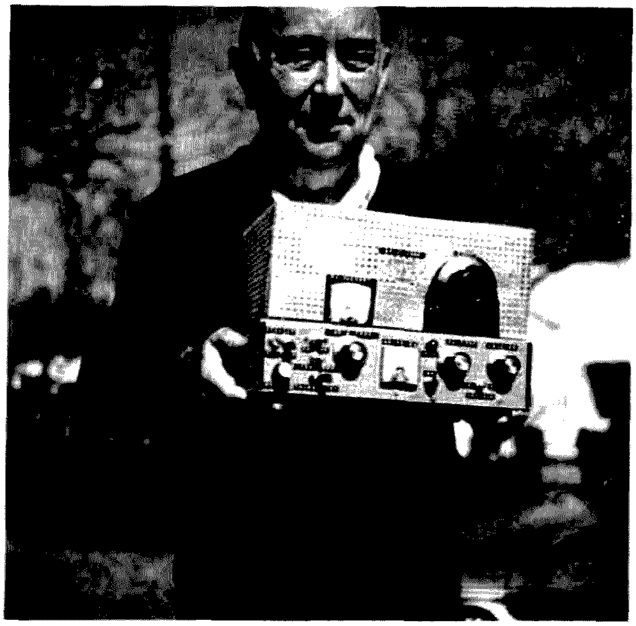
HOME BREW

I built this transmitter from scratch using mostly parts from my old black and white TV set. I have had many QSOs over the years with this little rig and a great many inquiries about it, so perhaps somebody will be interested in seeing it.

The circuit uses a 6AU6 VFO, 6W6 driver/mult. (TV audio output tube), and a pair of 6QD6s in the final (TV horiz. output tubes). And if my measurements are correct, I run a maximum of about 160 Watts input with about 120 Watts out.

John C. Conner
Chattanooga TN

Come to think of it, I haven't seen a good tube article come in for quite awhile — hmm. — Ed.



John Conner holds his home brew transmitter built from his old TV.

GREENBAUM REPLIES

This is in reply to WB6OIM's comments in Letters to the Editor, March, 1977, to my gross oversight by not touching upon the subject of 10m FM in my January, 1977, article, "Ten Meters: Dead Or Alive?"

My article simply explains one facet of enjoyment on 10m, namely Ten-Tenning. I did not intend to imply that any mode was better or more fun than another. This is a personal preference and also subject to considerable controversy.

I also would like to see more use of FM on 10m with a possible gentlemen's agreement to keep it on 29 MHz and above, avoiding the Oscar downlink frequencies, of course.

He mentions the thrill of working your next-door neighbor through a repeater 3000 miles away. Is this really necessary when you can do it simplex with a milliwatt?

Propagation conditions being alike, to work a DX station on FM with full quieting will still take an appreciable increase in power over other modes and can still be worked on SSB with a fraction of that power. Again, this is a personal preference.

To monitor 29.6 for band openings would prove fruitless if no one was on at that time or if the channel was being used by locals. This is why I prefer monitoring 24-hour beacons in different parts of the world to see if an opening has occurred and to where.

I do not intend to degrade FM, as it has proven its worth tenfold on the 2m band. My personal preference, as far as DX is concerned, is still SSB for its efficiency whether it's on 10m or 2m. To each his own.

Ten Meter Beacons

They transmit a carrier with CW identification.

SORRY 'BOUT THAT

In your Novice Q and A for March 77, you state that a transmitter can easily be set up for CW operation by plugging an af oscillator into the mike jack, and keying it.

A setup like that will have us Novices producing MCW or A2 operation, definitely a no-no on any Novice band, or any band at all below 50.1 MHz.

Please make the distinction between doing the above on an AM transmitter and an SSB rig (the latter will produce A1 operation).

Thomas Marquardt WB9UHX
Sharpsville IN

Briefs

Compiled by Warren Elly WA1GUD and Stan Miastkowski WA1UMV

Got a good ham radio news story? Drop us a line, or call it in, and take home the 73 publication of your choice, provided we publish your news tip. Be sure to specify which book you want. OK?

The WARC situation is not looking much better. The latest word from our Washington sources relates to the upcoming 5th notice on the frequency allocations tables proposed for the 1979 WARC conference. (A fourth notice will probably not contain any reference to the frequency allocations.) In the 5th notice, due out by late spring, the FCC is expected to drop two large segments of the 75m and 40m amateur bands. The proposed table (which still, of course, must withstand WARC scrutiny in 1979 and domestic debate at the FCC level) calls for *elimination* of amateur allocations between 3.9 and 4.0 MHz and between 7.2 and 7.3 MHz. Both segments would be allocated for international broadcasting. These latest developments would seem to indicate a better chance of amateur allocations at 10, 18, and 24 MHz, although they would probably be shared with other services. Underscoring the FCC proposals is word from the Canadian DOC, whose WARC allocations plan should be public by the time you read this. The DOC plan would also delete 3.9-4.0 MHz, along with 3.8-3.9 MHz, from amateur use. As for 21 MHz, the word at deadline was that there is a good chance of restoring the band to its original status of 21.0-21.450 MHz.

Senator Barry Goldwater K7UGA has again introduced RFI/TVI legislation in Congress. The bill, assigned number S-864, resembles previous RFI bills Senator Goldwater has written, all of which failed due to heavy lobbying by the manufacturers. Goldwater's latest bill would force TV sets and hi-fi equipment to be designed with better front ends and suppression.

Contrary to some conflicting reports in the media, instant upgrade of amateur licenses was effective at all FCC field offices on the first day of March. Initial reports from around the country indicate that offices have been packed to the walls with applicants during the last few weeks. In a *73* interview, Frank Skeiber, examiner at the Boston office, said that since the elimination of the license fee and the start of instant upgrade, Boston and many other field offices have been forced to schedule a separata day for handling the crush of applicants. Although Skeiber declined comment on the percentage of applicants who pass their exam, he did indicate that it seems that many people feel that with the no-fee test, if they don't pass the first time, they can try again.

The on-again, off-again comprehensive code exam plans of the FCC are on again ... this time, FCC spokesmen say, the exams will begin nationally on or before July 1st. But, it is important to emphasize that target dates have been set before, and a call to your district engineer's office *prior* to taking the trip may be in order. The word at deadline was that the code exam tapes had been duplicated, but the latest hang-up was the actual written exams.

As many prospective Novices have discovered, the FCC goofed on one version of the current exams. A circuit diagram Ohm's Law question is impossible to answer in its published form, so Gettysburg has been instructed to give all applicants taking that particular exam credit for the question.

We're still scratching our heads over this CB QSL from Switzerland. It came addressed to "BX 250," Peterborough, but we've been unable to find anybody answering that description. The Swiss op reports BX 250's signals were 58 to 9.

W1AW may be losing its license! That's if an FCC proposal becomes law. It all started with the incredible flood of license applications (CB and amateur) that has swamped Gettysburg since the first of the year. Over a million applications were received in January alone, and amateur applications reached the highest rate in history — well over 21,000 received in a month! A thousand 1x2 callsign applications were coming in per week at press time, and secondary license applications (undoubtedly fueled by the suspension of license fees) were coming in by the hundreds. By late February, FCC staffers were scrambling for a solution, and the results may not be very easy for most amateurs to swallow. The Commission has frozen all new secondary call applications, and proposed a rulemaking which would eliminate club and military club calls, secondary tickets, RACES calls, and special events calls. What's more, the proposal would phase out all existing secondary and club calls upon expiration. (The proposal may well be modified to set up a specific expiration date instead.) In the future, all calls except 1x2s and 2x2s for Extras (yes, 2x2s) will be issued systematically, thus eliminating all other requests for special or reassigned calls. The docket, assigned number 21135, can be commented upon until June 2nd, with reply comments due by June 30th. Needless to say, a strong reaction is expected from the League, as well as from clubs now holding club calls.

Hidetsugu Yagi, the man who did pioneering work on antennas in the early 1920s, died in January in Japan. He was 89. Besides the antenna that bears his name, Yagi did the first work in UHF. In 1926 he had equipment working on 2.5 GHz. Thanks to *Break-In*, the Journal of the New Zealand Association of Radio Transmitters.

Amateur radio played a big part in the Visveswariah Industrial and Technological Museum Science Fair in India this past January. According to the *ARC News Letter*, published in Coimbatore, VU2VTM was on 40 meters for the entire week of the fair, with more than 200 QSOs logged. Leaflets explaining amateur radio were distributed to all visitors, with a lecture transmitted by VU2ARC on the final day of the event. Incidentally, in the January *ARC News Letter*, 30 US stations were listed as being worked/heard by VUs, although only five made the difficult 20m SSB list — KP4AST, WA3TZT, WA4AMJ, WA4KMY, and W4JY.

Smokey reports don't violate the law, ruled a judge in Pontiac, Illinois. A CBer was cited by a state trooper for "obstructing a police officer," after the CBer gave the lawman's position over the air. The Radio Association of Erie PA said that the state is considering an appeal.

In an effort to decrease the amount of HF activity, the FCC is continuing to take legal action against members of the so-called "HF International" group. Late in January, show cause license revocation orders were issued against 21 alleged members of the group. According to a source at the FCC, six of those requested hearings, twelve waived a hearing, and three did not answer and were considered to have waived hearings. As this issue of *73* was going to press, the first of the hearings were taking place in Houston TX and Sacramento CA, before administrative law judge Walter Miller. Also scheduled was a hearing in Los Angeles on the renewal of the amateur license of Jack Randall, the alleged publisher of *SSB News*.

Meanwhile, the enforcement division of the FCC continues to work around the clock to apprehend offenders. Field Operations Bureau Chief Richard Smith told *73* that the 13 fixed monitoring stations have increased their staff and added a number of mobile monitoring vans. Smith added that the main concerns of the FOB at the moment are operators using illegal high power and the TVI that results.

In a related development, an Atlanta GA area CBer was recently sentenced to 90 days in jail on charges of using obscenity on the air. It's the second conviction this year that has resulted in a jail sentence.

The FCC's bandwidth docket (20777) may be delayed, but it's not dead. In early March came the first Report and Order on bandwidth (more are expected to follow), which sets harmonic and spurious emission limits on all amateur transmitters. The specifications call for suppression of at least 40 dB under carrier level for emissions under 30 MHz, and 60 dB for emissions between 30 and 235 MHz. The regulation affects *all* amateur equipment, whether home brew or commercial. FCC spokesmen say they believe most amateur equipment currently in use can pass the specifications, which in essence adopt the ITU standards recognized around the world. Another angle is that FCC engineers believe the new limits are likely to give them another handle on "black box" amplifiers and CB transceivers that are manufactured under the guise of being amateur gear. Keep in mind that this is not a proposal — it becomes law in late April.

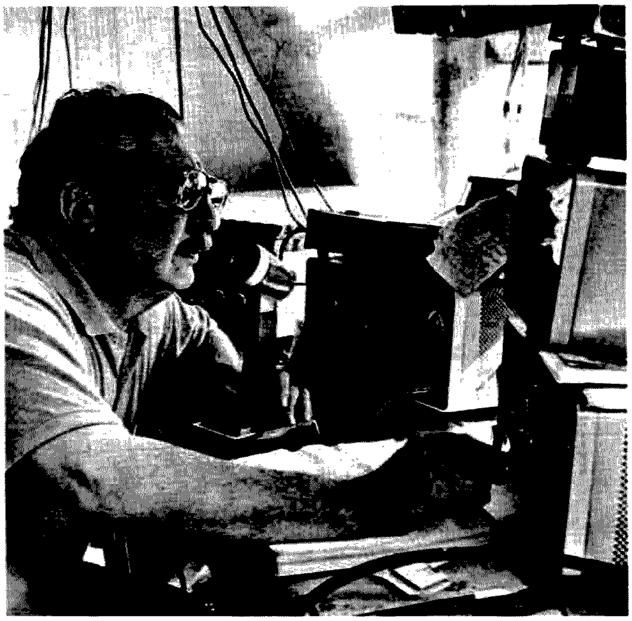
From one end of the country to the other, the interference problem continues to grow. In northern New Jersey, an amateur who saved the crew of a ship in trouble in the Caribbean (see "Be My Guest") continued his fight against a $2000 fine over zoning regulations and towers. In Texas, the state legislature saw introduction of a bill that would put $100 fines on interference convictions, without even considering the equipment being interfered with and the possibility that it could be at fault. Representative Samuel W. Hudson III reportedly introduced the bill after a citizen in

his district got nowhere with a TVI complaint to the Dallas FCC office. After some quick jawboning by the American Radio Council (led by Frederick Maia W5UTT), Representative Hudson agreed to let the bill die in committee. According to a report in the *Atlanta Journal and Constitution*, the National League of Cities is circulating a proposed model ordinance which would limit antennas to no more than 25 feet off the ground or six feet from the rooftop. In Lee, Massachusetts, a CBer was ordered by a district court judge to stop "the annoyance" of stereo interference. He ruled that RFI/TVI represents a disturbance of the peace. The CBer was given thirty days to comply. John Gallo, of the Personal Communications Foundation (PCF), was quoted as saying, "What we are experiencing is a crisis of unprecedented proportions . . . law suits are falling like rain in a hurricane against two-way radio operators." (The PCF has taken the position that interference ordinances are illegal because they are discriminatory and in violation of the 1934 Communications Act.) And in an AP story datelined Washington, Senator Barry Goldwater K7UGA was quoted as saying that he has an inexpensive remedy when neighbors complain about interference: "I just pick up a .00 or .50 resistor and go over and install it for them." We're hoping AP might run a correction, or, as K6QQN put it in a note accompanying the clipping, "Barry, I think you have a great idea, but I would stick with the first value of the two resistors." Thanks for the above items goes to K6QQN, WA4FSK, W5UTT, and WB2NEL.

The pressure on amateurs from the big money groups continues as WARC '79 draws closer. Recent spokesmen for the broadcast industry have noted that their services address millions of people every day, while the total number of amateurs is less than 300,000. Also mentioned was the fact that a comparatively large portion of spectrum space is assigned to amateurs which "could be better utilized elsewhere" . . . like broadcasting. Thanks to the *West Coast DX Bulletin*.

Reports continue to filter in to *73* of the valuable emergency services provided by amateur radio operators during the snow and cold weather that hit the east and midwest early in 1977. The Holland MI Amateur Radio Club reports that area hams manned CD and National Guard emergency shelters throughout the emergency. At several points, overloaded telephones caused 2 meter autopatch facilities to be used.

Alien hams operating in the U.S. under reciprocal agreements must still notify the FCC when operating portable. Although U.S. amateurs need not notify the FCC of portable operations, aliens must still file form 410 with Washington.



Hank Greenberg W2LTP, of Cranford NJ, saving lives and fighting to keep his antennas. Photo courtesy of The Daily Journal, *Elizabeth NJ.*

With all the controversy surrounding strict new tower ordinances and RFI complaints throughout the United States, *Overmodulation*, the newsletter of the Poinsettia Amateur Radio Club in Ventura CA, reminds us that it was the case of Whitehurst vs. Grimes in the United States District Court for the Eastern District of Kentucky in 1926-1929 that *denied* municipalities the right to regulate or restrict amateur operation.

Some postscripts to reports on the 220 MHz CB situation — *Sight and Sound Marketing* quotes Hy-Gain cofounder Andy Andros as supporting 220 CB. "It's a bad situation in that there are five megahertz of band space (at 220 MHz) occupied by only some 250,000 to 300,000 amateurs, and of that number it's estimated that only 150,000 at most, are active . . . on 220 MHz, it's estimated there are fewer than 3,000 amateurs who have had any equipment since the beginning of time." As for the amateur service, the other founder of Hy-Gain, Ted Andros, is quoted as saying that ham radio may have outlived its usefulness as a generator of technological developments through experimentation. Andy Andros (the Hy-Gain president) is quoted by *PerCom* as saying, "It is a national scandal that 2,000 to 3,000 people (hams) can hold on to that space, when 15 million CBers could use that band . . ." Thanks to WB2VUJ, WA2JXE, WB2ZLA, and *CFAR News*, Oak Park IL.

One area of interest to the authorities is the merchandising of "black box" linear amplifiers and amateur gear to CB types. The mailing of these advertisements may be in violation of Federal law. We are looking for any ads mailed to our readers, for the purpose of forwarding to the FCC. Especially of interest are sale sheets (and other paraphernalia) aimed at dealers. Several we've received include 100 to 500 Watt amplifiers, labeled "illegal for use on 11 meters." Think about the mark-ups on these TVI/RFI generators — a 100 Watt "bi-linear" which puts out "an honest 100 Watts," list $179.95, dealer price $92. Or a "Pride DX300 500 Watt Amature Linear" (their spelling), which promises a $200 profit for dealers. The same wholesaler proudly announces availability of a major line of amateur gear, just above his listings for "common mixer crystals" — great for putting that 11m rig up onto the "HF" band (or sliding a ham transceiver down to 11 from 10m)! Thanks to WA1FIH.

Before the FCC released its proposed ban on the sale of linears capable of 10 and 11m operation, the San Antonio Repeater Organization had already filed a counterproposal. The club's docket and legislative committee chairman, Robert Weaton K5PKK, says that abuse of the type acceptance exemption by manufacturers and dealers has made new regulations mandatory. The San Antonio group's petition asks the FCC to restrict the sale of transmitting and rf power gear to licensed persons, establish a dealer licensing program, and provide for mandatory penalties against anyone involved in the unlicensed use of transmitting equipment. As for type acceptance, the San Antonio petition argues against it: ". . . We submit that the inclusion of amateur equipment into the type acceptance program would fail to get to the heart of the problem. Conversely, a total ban on all forms of linear or rf power amplifiers . . . would be shortsighted and prejudicial to many lawful and conscientious users, but would also fail to stop the availability of high-powered transmitters to unlicensed operators. The amateur transceiver offering a power input of two kilowatts PEP, with 11m "receive only" provisions, would simply replace the lower powered versions currently available."

The San Antonio petition concludes that the issue is not the actions of the majority of radio amateurs who would be affected, but instead commercial greed. "We are hopeful that strong regulation of sales will stop the rash of new state and local laws attempting to deal with the radio and television interference problem, most of which . . . usurp the Commission's authority to regulate transmission of radio signals."

Our friends to the north have not gone unaffected by the linear amplifier problem. Shortly after the FCC proposed a ban on the manufacture and sale of commercial amps covering 24-36 MHz, the Canadian DOC released a plan of its own. According to reports in *The Canadian Amateur*, the sale of amplifiers would have to include (within ten days) paperwork addressed to the DOC. Specifically mentioned in the Canadian proposal is the General Radio Service (CB), but the Amateur Service is not mentioned. The proposal calls for $1000 maximum fines and up to a six month jail term. Editorializing on the DOC plan, *The Canadian Amateur* didn't seem very optimistic: ". . . this measure is coming on the scene too late to prevent the present chaos prevailing in the GRS, which sports illegal transmitters, illegal amplifiers, illegal procedures and various and sundry other illegal operations, much to the detriment of those who need the service for legitimate purposes." But the strongest point of the editorial was aimed at the DOC itself. ". . . In our opinion, this amendment will be as useless in cleaning up the situation as the rest of the Radio Act has been — unless the political leadership of the DOC and its top management show some fortitude in enforcing the proposed amendment and the rest of the Radio Act and the Regulations . . ." Along with the linear amplifier proposal, however, the DOC moved against RFI/TVI on the manufacturer's side. The plan would ban the sale of "machinery, apparatus, or equipment that causes interference to radio reception," within yet to be defined (at press time) limits. Yet another section of the Canadian proposal limits the sale of emergency locater transmitters (ELTs) to aircraft and seaworthy vessels. The closing date for comment to the DOC was March 17th, although an extension had not been ruled out at deadline.

A stolen repeater? Yes, unfortunately that's right. WRØALU, the only free-access autopatch repeater in Minneapolis/St. Paul MN, abruptly went off the air on March 2nd. The 16/76 machine, located on the 23rd floor of the Shellard Tower building, had been vandalized. Left behind were

the transmitter and receiver strip, but the autopatch and duplexer had been ripped from the rack. The thieves apparently jimmied a stairway door. Owner KØFHC was expected to have the machine back on the air by the time you read this. Thanks to WBØSCV.

Still more changes in the works at FCC — the Commission has proposed eliminating the 4 month requirement for notification of a change in station location. According to FCC staffers, the idea is to leave notification up to the judgment of the individual amateur — keeping in mind the remaining regulation that FCC mail be able to reach you promptly. Another issue under consideration is elimination of group Novice exam mailings, a procedural matter not requiring a rulemaking. FCC spokesmen say that hams have let them down by failing to send back unused exams, so the result is counterproductive. Instead of cutting the paperwork, as the FCC had hoped, only more paperwork has been created!

With the release of the dockets on linear amplifiers and type acceptance of amateur radio equipment, the FCC also had something to say about ham radio. Chairman Richard Wiley wrote of his reservations, "... While I concur in the Commission's proposals to ban use of linear amplifiers in the 11m citizens radio band, and to require type acceptance of amateur equipment, I must admit to doing so with some reservations ..." Wiley went on to say, "... in attempting to deal with the rapidly proliferating and sometimes troublesome CB service, we may appear to be penalizing the amateur community which, in my judgment, is one of the most professional and self-regulated services within the Commission's jurisdiction ..." And Wiley concluded that, whatever happened to the linear amplifier and type acceptance proposals, he wanted to take the opportunity "... to express my respect and admiration for the amateur community..."

Chairman Wiley also had some comments of interest in testimony before the House Appropriations Committee in Washington. The topic was the FCC's nearly 60 million dollar budget. Wiley, according to wire service reports, testified that the FCC will not attempt to institute a new fee schedule, because of a lack of accounting personnel necessary to meet the federal court order which struck down the original schedule. Documentation filed with the committee showed that the FCC has collected over $150 million in fees since 1970.

There isn't much left of Guglielmo Marconi's giant antenna system erected at the turn of the century on the dunes at South Wellfleet MA. There were originally twenty masts in a 200-foot circle on the sand dunes, but they blew down in a northeaster during November of 1901. Marconi replaced them with four 200-foot wooden towers. Today only two of the tower bases remain, the rest of the famous pioneer's station having been eaten by the erosion of the Atlantic. As reported earlier on these pages, the Town of Barnstable Radio Club will celebrate the 75th anniversary of Marconi's first transatlantic radio transmission. We've learned since that the US Postal Service is working on a commemorative stamp for the event, which runs multi-operator style from the South Wellfleet site between next January 14th and 22nd. The Barnstable Club still needs help with donations, and is offering a commemorative cachet envelope, 10 of which are available for a donation of $1.50, postpaid. Contact Robert J. Doherty W1GDB, RFD 1, 14 Pine St., Sandwich MA 02563.

A second phase III satellite for amateurs may be in the works for 1979. AMSAT president Perry Klein told *73* that NASA approached them early in March with a tentative proposal to allow one of the space shuttle flights to carry an AMSAT satellite. At press time, Klein said it was not a sure thing, but looked good. Asked if AMSAT had the capabilities for building a second phase III spacecraft, Klein replied that the goal of a new fundraising program just underway has been raised to $250,000 over the next three years, with $50,000 hoped for by the end of 1977.

Under the program, contributors can buy solar cells for the new satellites in multiples of $10.00. Each contributor will receive a certificate attesting to the fact. Each of the phase III satellites will carry approximately 2500 solar cells.

Both Oscar 6 and Oscar 7 continue to have their problems. Oscar 6, according to Klein, is "limping along," despite battery problems. Oscar 7 was reported to be jumping modes inexplicably early in March. Klein added that the mode jumping was taken care of by Canadian control station VE3SAT, the first completely microprocessor-controlled command station. It's hoped that all earth stations will eventually go to full computer control. Both phase III satellites will have micros onboard.

An FM repeater system aimed at keeping hunting and fishing parties in reliable radio contact with settlements up to 75 miles away is now being tried out in an Eskimo community in Quebec's arctic region.

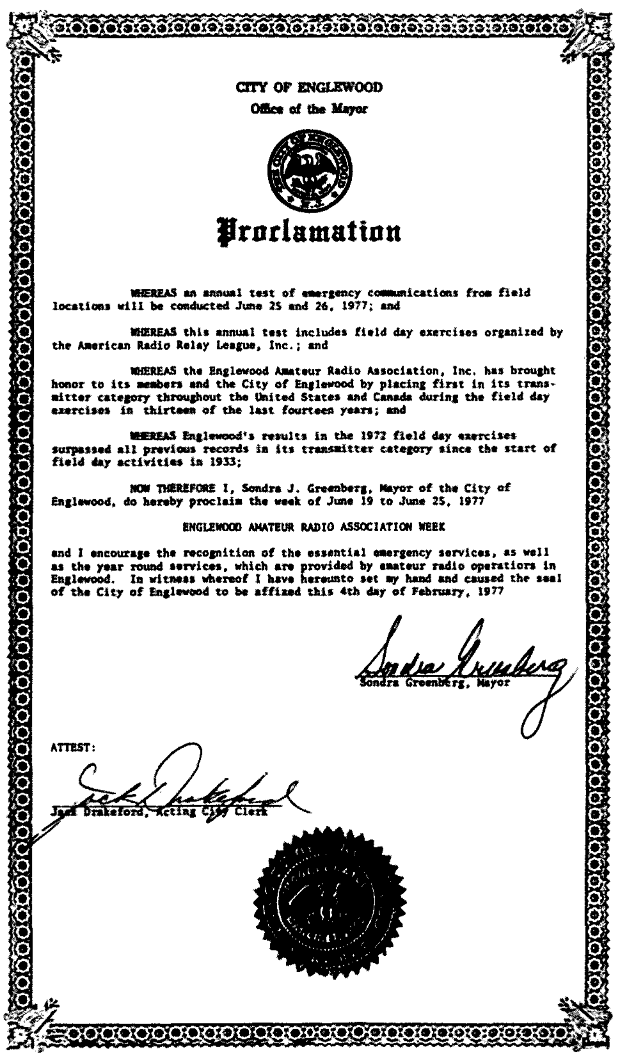
Snowmobile portable rigs will work back to the repeater base station in the settlement of Koartac, about 300 miles north of Fort Chimo.

The original development work, complete with a phone patch, was tried out in the Ottawa area utilizing a 2 meter repeater set up by DOC's Communications Research Center in the hills north of the city. The station, VE2KPG, boasts an autopatch, and with the participation of local amateurs, provided development information for the prototype now being given field trials. The station has now reverted to amateur use. Thanks to the *Canadian Radio Amateur*.

In a trend that seems to be surfacing throughout the country, the theft of two-way radios from cars has been decreasing over the past few months. The Plano TX amateur radio club reports that in the Dallas area the theft rate dropped for the seventh month in a row. In January, 390 radios were ripped off, as compared to an average of 920 per month throughout most of 1976.

Sondra Greenberg, Mayor of Englewood NJ, has declared the week of June 19 to June 25 Englewood Amateur Radio Association Week, in honor of the city's amateur club. She cited the fact that recognition should be given to amateurs for their essential emergency services. The Englewood Amateur Radio Association has placed first in its category during 13 of the last 14 field days. In 1976, they were in a class by themselves (21A), chalking up a total of 10,186 points (with 2845 contacts).

Our English friends, who have been leagues ahead of us for years in the microwave ranges, have adopted a new callsign system for ATV and SSTV. A report in *CQ-TV*, published by the British Amateur Television Club, says that the Home Office has discontinued issuance of /T (television) licenses. Instead, existing amateur sound A and B licenses will be replaced with new ones, which will include both ATV and SSTV authorization.



CITY OF ENGLEWOOD

Office of the Mayor

Proclamation

WHEREAS an annual test of emergency communications from field locations will be conducted June 25 and 26, 1977; and

WHEREAS this annual test includes field day exercises organized by the American Radio Relay League, Inc.; and

WHEREAS the Englewood Amateur Radio Association, Inc. has brought honor to its members and the City of Englewood by placing first in its transmitter category throughout the United States and Canada during the field day exercises in thirteen of the last fourteen years; and

WHEREAS Englewood's results in the 1972 field day exercises surpassed all previous records in its transmitter category since the start of field day activities in 1933;

NOW THEREFORE I, Sondra J. Greenberg, Mayor of the City of Englewood, do hereby proclaim the week of June 19 to June 25, 1977

ENGLEWOOD AMATEUR RADIO ASSOCIATION WEEK

and I encourage the recognition of the essential emergency services, as well as the year round services, which are provided by amateur radio operators in Englewood. In witness whereof I have hereunto set my hand and caused the seal of the City of Englewood to be affixed this 4th day of February, 1977

Sondra Greenberg

Sondra Greenberg, Mayor

ATTEST:

Jack Drakeford, Acting City Clerk

A proclamation from the mayor of Englewood NJ honoring the accomplishments of the Englewood Amateur Radio Association.

Japanese amateurs working on the AMSAT A-O-D mode J transponder prototype. The ARRL will be responsible for all operations aspects of the satellite, which will be designated AMSAT-OSCAR 8 after launch late this year.

Officer Jay Webb of the Plano TX police and Marvin Arnold WB5BWW check out 5/8 wave 2m antenna during simulated emergency test that saw all police communications traffic switched to amateur frequencies.

Here are some details of the AMSAT-ARRL agreement on OSCAR 8, as reported in last month's "Briefs." According to the document signed by representatives of both groups, the ARRL will pay AMSAT $50,000 within two weeks after launch (the delay to allow a period of time to assess performance). ARRL General Manager Dick Baldwin's draft goes on to say, "Once in orbit, it is understood that both the ARRL and AMSAT will consider the spacecraft to be in the public domain without specific ownership." Baldwin's letter to AMSAT goes on to outline the League's intentions: "Our principal interest in this spacecraft is for providing continuing ten meter downlink signals for the OSCAR Education Program, and the performance of the spacecraft will be evaluated with this application in mind." The agreement calls for AMSAT to continue offering technical assistance on a no cost basis during the operational lifetime of the spacecraft. As we reported earlier, the ARRL, in addition to the $50,000 payment to AMSAT, will loan two staffers to work full time (at League expense) in Washington on the A-O-D project.

A word of caution about tubes and transistors using beryllium-oxide ceramics: While normal use is perfectly safe, the fumes and dust are highly toxic and can result in serious injury or death. Almost all ceramic power transistors use BeO, as well as Eimac 4CX250 tubes. Most are not labeled as containing the chemical. Never alter, grind, or clean any ceramic part of the tube that could generate dust or fumes. They should be returned to the manufacturer for disposal. Thanks to VE3AAC.

As mentioned in last month's "Briefs," part of the observance of Armed Forces Day will be the traditional military/amateur communications tests. Crossband operations will be conducted from 1300 UCT on May 21 to 0245 UCT on May 22. Military operators will transmit in their portions of the band and listen on amateur frequencies. The following is a list of frequencies that will be used. The left-hand column is the military frequency in kHz unless otherwise noted. The right-hand column is the appropriate amateur band in MHz.

NPL, (Naval Communications Station, San Diego CA)

14.389 (1500Z-2100Z)	SSTV	14.225-14.250
7.370 (1500Z-2100Z)		7.16-7.19

NMH (Coast Guard Radio Station, Alexandria VA)

14.470	SSTV	14.225-14.250
7.346.5		7.16-7.19

WAR (Army Radio, Washington DC)

4001.5	CW	3.5-3.75
4020	LSB	3.775-4.0
4030	RTTY	3.65-3.775
6997.5	CW	7.0-7.15
14405	CW	14.0-14.2
20994	USB	21.25-21.45

NAM (Naval Communications Station, Norfolk VA)

3385	CW	3.5-3.75
4040	LSB	3.775-4.0
6970	LSB	7.15-7.3

AIR (Air Force Radio, Washington DC)

4025	LSB	3.775-4.0
7305	LSB	7.15-7.3
7315	CW	7.0-7.3
14397	USB	14.2-14.35

The "CW" receiving test will be conducted at 25 words per minute for any person capable of copying International Morse Code. The "CW" broadcast will be a special Armed Forces Day message from the Secretary of Defense to all participants. A ten minute CQ call for tuning purposes will begin at 22/0300 GMT. The Secretary of Defense message will be transmitted precisely at 22/0310 GMT from the following stations on the frequencies listed.

WAR – Army	4030, 6997.5, 14405
NAM – Navy	3385, 7301, 14400
NPG – Navy	4005, 6989, 14375, 49.995 MHz, 143.995 MHz
AIR – Air Force	7315

The RTTY receiving test will be transmitted at 60 words per minute. A ten minute CQ call for tuning purposes will begin at 22/0335 GMT. The special Armed Forces Day message from the Secretary of Defense will be transmitted at 22/0345 GMT. Transmission will be from the following stations on frequencies listed.

WAR – Army	4030, 6697.5, 14405
NPG – Navy	4010, 7347.5, 13922.5, 148.410 MHz
AIR – Air Force	7315

Transcriptions should be submitted "as received." No attempt should be made to correct possible transmission errors.

Time, frequency, and callsign of the station copied, as well as the name, callsign (if any), and address, including zip code of the individual submitting the entry, must be indicated on the page containing the test. Each year a large number of acceptable copies are received with insufficient information, or the necessary information is attached to the transcription and was separated, thereby precluding the issuance of a certificate.

Entries should be postmarked no later than 25 May, 1977, and submitted to the respective service copied.

Stations copying NAM and NPG should send their entries to: Armed Forces Day Test, Chief, Navy-Marine Corps MARS, Building 17, 8th St. & So. Courthouse Rd., Arlington VA 22204.

Stations copying WAR should send their entries to: Armed Forces Day Test, Commander, United States Army, Communications Command, ATTN: CC-OPS-OM, Fort Huachuca AZ 85613.

Stations copying AIR should send their entries to: Armed Forces Day Test, Air Force Communications, Service/DOYF, Richard Gebaur Air Force Base MO 64030.

The Plano TX Police Department recently tested an emergency communications system provided by the Plano Amateur Radio Klub and Plano area amateur radio operators. All car-to-car and car-to-base communications were performed on the two meter amateur band. This exercise was a Civil Defense simulated emergency test to familiarize the police department personnel and amateur radio operators with operating techniques that might be utilized in the event of a natural disaster or failure of the police department radio equipment. Plano area amateur radio operators undergo regular training by the National Weather Service and provide weather watchers in the event of severe weather. During severe weather, the amateur radio operators provide a station at the police department, and the National Weather Service has direct contact with the amateurs. Frequently, the National Weather Service requests the amateurs to check storm cells in a particular area that look threatening on the weather radar. Thanks to W5FQA.

A County Circuit Court judge has ordered a temporary injunction against Trigger Electronics. The injunction, which bars any catalog mailings or magazine advertisements, is to be followed with a request for a permanent injunction, according to Assistant Illinois Attorney General John McPhee. Among the witnesses testifying against Trigger owner Irael Treger: an official of the Federal Trade Commission, six amateurs, and an SWL. The rub may come, however, when people who have ordered merchandise from Trigger and not received it, try to collect. The consumer fraud office at the Illinois AG's office

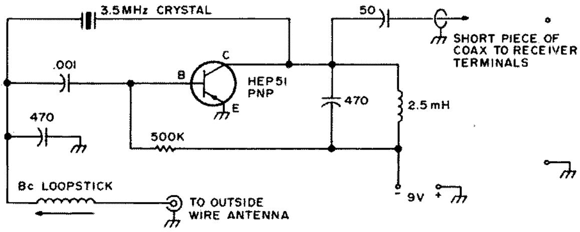
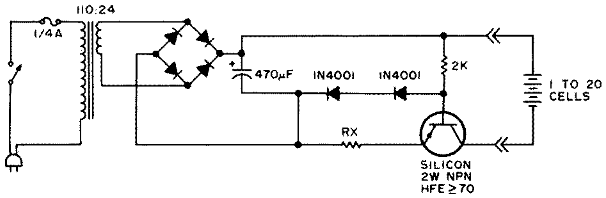
Circuits²

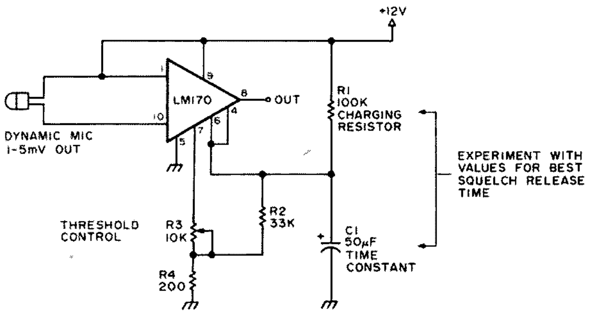
Want a free copy of any 73 publication? Sure you do. Just send in your favorite circuit, or even one that you don't especially like. If we print it, you take home the book of your choice. Just be sure to specify which book you want. OK?



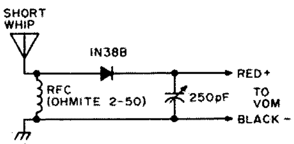
Here's a simple LF converter allowing coverage from 25 kHz up to 500 kHz. Be sure to use short coax from the converter to receiver antenna input. Here's how to use it: Tune receiver to 3.5 MHz, peak for loudest crystal calibrator signal. You are now tuning the 25 kHz range. As you tune your receiver higher in frequency to 3.6 MHz, you're tuning the 100 kHz range. 3.7 MHz puts you at 200 kHz, 3.8 MHz equals 300 kHz, 3.9 MHz yields 400 kHz, and 4.0 MHz gives you 500 kHz. Thanks to James Dates W2QLI.



A great way to keep those nicads at full charge. R_X = 0.6 volts divided by the desired current limit. We suggest 12 Ohms at R_X for 45 mA into 450 mA/hr AA cells. Thanks to Arvid Evans K7HKL.

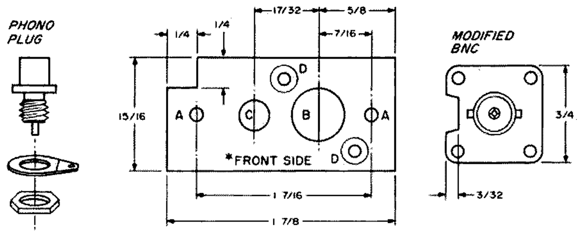


Wondering how to squelch out amplifier fan noise and assorted ham shack racket between sentences? This circuit will do all that, and make for more reliable VOX operation when a compressor is in use. Built as an addition to the IC compressor-expander circuit published in the January '77 73, the audio gate is placed in the early stages of the audio chain. It attenuates the audio path below a preset input level, and functions just like the squelch circuit on your 2m radio. Thanks to John Webber WA7ZMC.



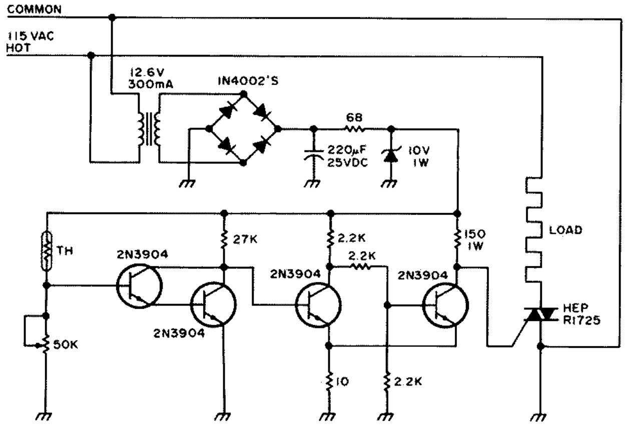
Ever wondered how to make a VOM do double duty as a field strength meter? Well, here's how to do it, with thanks to Dick Peters WA1PWF.

Here is a handy way to get -9 volts for your 1702A EPROMs from your regulated -12 volt power supply. Note: Each diode drops 0.6 volts (5 x 0.6 = 3.0 V). Diode type is 1N4004 (or equivalent). Current limited to 1 Amp through diodes. Thanks to Don Parks K4IJV.

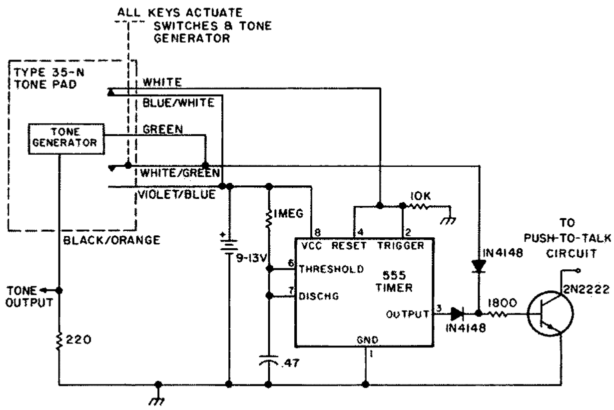


*FACES TO REAR OF RADIO

If you're as fond of phono plug rf connectors as we are, you'll be interested in this mod for the Heath 2036 2m FM transceiver. To replace the phono plug with a BNC, first make the adapter illustrated above using 1/16" aluminum stock. Drill "A" holes with a #33 drill and tap them with 6-32 threads. Drill "B" hole 7/16" and "C" hole 1/4". Drill two "D" holes and countersink for 4-40 flat head screws. Then attach the phono plug to the adapter with the nut and ground lug on the rear side, at hole "C". (Note that it is advisable to use a washer on the front side for clearance at the PC board.) Now attach the modified BNC connector with the notch towards the phono plug nut. The flange is on the back of the adapter. Attach the adapter to the rear panel plate with the notch at the slide switch cutout using two 6-32 screws. It may be necessary to enlarge the oblong hole slightly. Drill a round hole in the antenna connection pad on the power amplifier PC board, just large enough to accept the BNC pin. Now assemble in a manner described in the Heath manual, starting on page 103. (Be careful to pay attention to the tightening and strain warnings.) Thanks to Bill Chedeville W3GOD.



Believe it or not, this circuit was originally designed to control the temperature of water in a slow cooker at the ideal level to make yogurt! The temperature controller uses a model K600A thermistor available from Allied Electronics. The potentiometer value can be changed to allow triggering of the circuit at proper temperature. A polarized power plug should be used for proper circuit operation. Thanks to Jim Arner, Jacksonville FL.



Here is a way to end the autopatch-while-in-motion blues. The circuit operates your rig's push-to-talk whenever any touchtone pad button is pushed, thus ending the need to engage mike before dialing. The circuit remains active for about 2 seconds after the button is released. Thanks to Harry Ketler W1DGD.

Hank's Dilemma

His name is Alfred "Hank" Greenberg W2LTP. Greenberg is a retired deputy sheriff in Cranford NJ, and he's up to his ears in legal trouble over his antenna farm. Greenberg says he's the victim of political shenanigans, and his antenna fight is bound to affect similar cases in New Jersey, and possibly across the country.

More than 30 years a licensed amateur, Greenberg is considering a mortgage on his house to finance his appeal of a $2000 fine brought by a municipal court judge earlier this year. At issue is the classic question of an amateur's right to erect antennas.

Greenberg's troubles began last September, when a neighbor complained his four 55' telephone poles were an eyesore. That brought down the local building inspector, who promptly filed a complaint charging Greenberg with violating the local building code. Greenberg erected the poles during the summer of 1975, hoping to stack beams on them to supplement his Christmas tree array on a frontyard tower. Four poles were put in, two in his side yard, and two in the rear. Two of the poles aren't even in Cranford, because the Kenilworth town line runs through his property.

The Cranford building inspector told Greenberg the issue wasn't TVI. Instead, the town was wondering why he hadn't applied for a building permit before erecting a structure over 16 feet high. Greenberg contends that no one has ever had to obtain a permit in Cranford for antenna towers before and he points to much higher antenna supports in the commercial district, including the town's own fire station, public works building, and first aid squad headquarters. All are higher than Greenberg's telephone poles, and he contends that the others never even asked for permits. In one case, the town actually sent people over to direct traffic while the tower was being put up. Greenberg then asked the town if it wasn't violating its own ordinances. That approach got nowhere, and Greenberg's lawyer, Elson Kendall W2INL, advised that it was time to go to court.

On December 8th of last year, Hank Greenberg was convicted of violating the Cranford zoning ordinance and fined $2000. What's more, Greenberg was ordered to pay $200 a day for each day the phone poles remained in the air after January 15th. Sixty amateurs turned out for the court case, all prepared to testify on Greenberg's behalf, but Judge Charles J. Stevens would not let them testify, ruling that no further testimony was necessary. Defense witnesses who did get to take the stand included Dr. Jerry Sevick, a physicist and antenna expert with Bell Labs, and Dr. James M. O'Kane, a sociologist at Drew University. Dr. O'Kane testified on the social value of the volunteer services performed by amateurs, and his testimony would, months later, be underscored by an emergency at sea.

The decision was quickly made to appeal Judge Stevens' ruling, and as this issue goes to press, Hank Greenberg says he's determined to win. Greenberg is so committed to his cause that he's planning to mortgage his house, if necessary, to continue the fight. In the interim, Kenilworth town officials moved to bring charges of their own on the poles within their borders.

While he waited for the appeal to come up in county court, Greenberg's case began to attract more and more attention in the local media. Front page stories in the *Elizabeth Journal* and *Daily Journal* soon brought a flood of letters to the editor. Most supported Greenberg. Wrote Irene Kowalski of Elizabeth, "This is a sad state of affairs when a retired man has to mortgage his home in order to defend himself against attacks by officials. People who attended his trial have told me that everything he, his attorney, or witnesses had to say was objected to . . ." Wrote Jim Dembeck of Elizabeth, ". . . It seems to me that the question boils down to this: Is one man's hobby, for fun, justified, when it has an adverse effect upon his immediate neighbors? . . ." And Lorraine Bardack of Roselle Park wrote, ". . . One man who lives behind Mr. Greenberg told him that he could put his antenna on his garage . . . I know of the fine work Mr. Greenberg has done . . ." And so it went, until February 18th — when Hank Greenberg's "unsightly" telephone poles helped save nine lives.

According to Greenberg, it was a pretty normal Friday night at W2LTP. "It was about 4:30 am and I was working KH6FC on 40m SSB," Hank told *73* in an interview. "All of a sudden I heard this super-weak signal on frequency calling 'break — Mayday, Mayday — this is W3' . . . but I couldn't get the rest." Several tries later, Greenberg had copied W3LBU maritime mobile, but getting the rest of the frantic call wasn't easy. Minutes passed and the pieces began to fit together — it was a distress call from a

RETRACTION

It was stated in the newspages last month that Robert Booth W3PS not only is the General Counsel of the American Radio Relay League (ARRL), a nationwide organization of amateur radio operators, but also represents the National Association of Broadcasters (NAB) and, therefore, does not and cannot adequately represent the ARRL. That statement was incorrect. Although Mr. Booth and his law firm, Booth and Freret, do represent AM, FM, and TV broadcast stations before the FCC, we know of no instance in which such representation has limited or conflicted with his representation of the ARRL and amateur radio before the FCC, Congress, or elsewhere. We offer our apologies.

The QTH of Hank Greenberg W2LTP. His property happens to lie in two towns, both of which are trying to force him to remove the telephone poles.

vessel somewhere in the Caribbean. The bilges were flooded, and the ship's pumps were not working. W2LTP, with the help of those "unsightly" antennas, kept W3LBU transmitting and called the Coast Guard in New York. They called New Orleans and Galveston and the FCC. Direction-finding put the troubled craft (named the *Explorer*) between Cuba and Jamaica. Five hours later, a Coast Guard plane out of St. Petersburg FL dropped portable pumps to the *Explorer*, and the twin-masted 180-foot sailing vessel and her crew of 9 were saved.

Hank Greenberg speaks of the rescue matter-of-factly. He's got other things on his mind these days . . . like how he's going to pay the $5000 worth of legal expenses his lawyer estimates the case will end up costing. The appeals process was just getting underway as we went to press, and Greenberg says he's confident of a reversal. We'll follow up on W2LTP's ordeal later, but in the meanwhile, there is a contributions drive underway to help out with the legal bills. Send them to Amateur Radio Legal Defense Fund for the Benefit of Hank Greenberg W2LTP (ARLDF/W2LTP), Midlantic National Bank/Raritan Valley, PO Box 996, Edison NJ 08817, Attention — Mr. S. J. Lieberman WA2FXB.

Greenberg's attorney told *73* at deadline that as the appeal case opened in Union County Court, the judge overruled the lower court, ordering subpoenas re-issued for defense witnesses. (Municipal Judge Stevens had denied them on a technicality at the lower court level.) In the view of Greenberg's lawyer, that means Hank will finally get his chance to present his defense. Among the records Attorney Kendall has subpoenaed: the Cranford building inspector's files on permits.

Over a Barrel

Summer vacation time is almost upon us again, and it's probably a good idea to start planning that annual trek. In that same vein, we present one ham's letter home during last summer's vacation . . . a letter delayed, undoubtedly, by the Pony Express. — Ed.

Dear Mort:

Harriet and I made it OK. The trip was nearly perfect. The car ran fine all the way to Paris, but I had a little trouble there. It all started when I noticed we had stopped, and I had done nothing to stop us. Oh, don't be too worried, because we didn't stop fast. We just sort of coasted. I was talking to a fella near there on the rig, and next thing you know, the whole car was screaming at me to do something. Homer jumped into the front seat sort of suddenly, and sat on my Atlas. I couldn't see where I was. I was lost. For all I know I could have been on 80 meters and all of a sudden causing QRM or something. I hit him with my logbook. It was a good hit, it was, right on his wet nose. I think I scared him, 'cause in all the confusion Homer ran away. Harriet started crying, and the kids kept screaming something about my antenna . . . and their model airplane . . . they wanted us to go fast again so their plane would fly some more. I tell you, Mort, I almost lost it right there by the Walkers' mailbox.

Well, Mort . . . I see we've been a little deregulated again by Washington. Boy, when I heard about it I was furious . . . really mad! Just think! I shouted to myself, no more comedy when I forget what call area I'm in, no more DX on the 2 meter rig until you ask the guy where he is . . . no more . . . and then it hit me!

Ya know, Mort . . . the FCC doesn't *make* us call CQ . . . we just sort of do it. Fact is, the FCC doesn't make us hams do a lot of the things we do. We do them 'cause they're fun. Like RST and QTH. We don't have to do that; if someone really wants to know where we are, they could look us up . . . but all the hams do those things 'cause they're part of the fun we have on the ham. Radio, I mean, ya know?

I gotta admit, it took me a time or two to make sense out of all this, but I think I'm doin' it. The FCC sort of trusts us, in one sense . . . probably cause they're over a barrel over not having enough people or money or something like that . . . why, when a government agency suddenly gets real popular, all that red tape, budget approvals, and the like could take years.

Think of the tons of paperwork this whole thing is gonna save 'em. Maybe they'll take some of the money they save, and send someone after that terrible noise I've been hearing all over 40 meters.

Seems like there's something in Part 97 about improving amateur radio (oops, I missed that one, didn't I Mort?) . . . something in there anyway about improving amateur radio thru rules that make us sharpen our skills, and advance the communications thing. Maybe that goes for relaxing rules, too.

More I think about it . . . more I think I'm gonna make "mobile," "portable," 5, 6, 7, KL7, or lost . . . a part of my every transmission . . . just like always, and show them that we don't need all that paperwork to make good hams out of us.

Whaddya think, Mort? . . . think it's a good idea?

73,
Woody

P.S. The family don't like Mauve, Tex., too much. We're gonna keep going.

Reprinted from the bulletin of the Plano Amateur Radio Klub, Plano TX.

The CB Debate

With WARC, repeater deregulation, instant upgrade, linear amplifier bans, and type acceptance of amateur equipment all bottling up our perspective on where ham radio is going, it might be time to think again about CB. Here's one man's perspective . . . but the editorial door is wide open for more. What's your reaction to WB4APC's ideas? — Ed.

All too often, we refer to the CBer as an undesirable amongst us. Many an old-timer, myself included, can remember when it was unthinkable to be seen talking to a CBer. For many years, both the ham and the CB operator have gone their separate ways, each enjoying his own hobby. Whether we like it or not, CB radio is here to stay, and it is time to take a look at what each has to offer the other. Most of us are familiar with the advancements being made in communications. True, hams have made the most contributions to the state of the art, but we also are able to find a wide variety of people using Citizens Band radio.

Many a CB operator has an interest in amateur radio but does not have the opportunity to really get to know and see what amateur radio is all about. For example, I live in a small town close to a large military installation. I have had amateur call plates on my car for four years now, and have yet to meet more than two other hams in my area. Having recently started a small business, I found the need for a two-way radio that would enable me to keep in contact with my office and also allow my customers to contact me with their questions or problems. I bought a CB radio and applied for and got my FCC license.

Then I started to meet and get to know the average CB operator. Through my day by day association with them, I found that the majority of them are very sincere in their use of the radio. I also learned of the real dedication of the CBers in wanting to help others, no matter how small or large the need.

In the area where I live, CBers have set up 24-hour coffee breaks along major interstate highways. They offer free coffee and donuts, and a chance to stop and rest on a long drive. They also have mobile units patrolling the interstates, working with CB radio-equipped State Police cars and wreckers, to offer assistance to stranded motorists. Their action puts many a stalled car back on the road home, or gets them out of the traffic lane, thereby removing a possible traffic hazard. During last Memorial day alone, there was not one accident on the interstate between Louisville and Bowling Green, Kentucky.

In addition to the coffee breaks, during the tornado of 1974 in Brandenburg, Kentucky, CB operators were working around the clock to assist the local police and fire departments, and even used their personal cars for ambulances. At the end of the three day disaster, we knew exactly how many people were lost or missing.

How wonderful it would be if we could get amateurs and CBers working as a team, to coordinate the emergency operations and eliminate dupli-

cation of effort. With CB units furnishing the "eyes" and helping to perform traffic control and person counts, and the amateur-CB station acting as a sort of control-coordinator station, we would have an unbelievable system of radio communications. Imagine the capabilities of the well-equipped ham station, with CW/SSB and RTTY capabilities. Almost any type of emergency assistance could be well on its way in a matter of minutes. In addition, the amateur station, with phone patch capabilities, could contact Red Cross officials, the governor, and other officials directly. In this manner, help could be sent when and where it is needed the most.

With the use of SSTV, facsimile, and video tape systems, actual pictures could be transmitted to the proper officials, showing them conditions as they really exist. Can you imagine the effect of such a system, not only within your own state, but on a nationwide basis? Who knows what may develop? With the ARRL (ugh) talking about a Communicator license, and the FCC looking for more CB frequencies, maybe someday a common frequency will be allocated where hams and CBers may talk to each other. The potential is unlimited, and in this modern age of computers, even a list of standby emergency stations and their capabilities could be maintained. In addition, a list of emergency supplies, alternate emergency routes, and up-to-date status reports would be only a button away. Let us remember, that as amateurs, there are many avenues of research and system development still open to those that are unafraid to try. We can make it work!

Knighthood

Amateur radio operator David Urfer EL5B/WA7ROJ had the honorary title of Knight Official in the Humane Order of African Redemption bestowed upon him for his role in aiding the Liberian government in bringing the 1972 Lassa fever epidemic under control. The presentation was made by the Liberian Minister of Health and Welfare, on behalf of President Tolbert of Liberia.

Dave received the knighthood because he had stayed at his amateur radio station for over 86 consecutive hours, coordinating communications between the health authorities in Zorzor and Monrovia, Liberia, and the United States. He had been a ham for less than one year, and was a maintenance supervisor for a Lutheran hospital located in Zorzor (a remote section of Liberia).

Lassa fever is named after the town in Nigeria where the first case was isolated. It is highly contagious, like cholera, and the dead are buried hurriedly.

All traffic on 20 meters, during the crisis, was coordinated between Dave EL5B, Eloise Duncan EL2AQ, Walcott Benjamin EL2BA, Bruce Adams EL2CG, Dr. Gadegbeku of the Zorzor hospital staff, and Charlie Wells, Jr. K4SKI, located in the U.S.

The date that called these ham radio operators into action was April 12, 1972 – Easter. Dave was on the African net on 14.292 MHz around 2130 GMT, with Walcott and the other hams living in that part of the region. During the casual round table, Dave mentioned that there was an outbreak of some sort going on in Zorzor, and that the doctors, Paul Merten and Joe Baum, were not sure of what it was.

A letter had been mailed, but the radio proved to be timesaving when EL2BA made a phone call to the Minister of Health and Welfare to notify her of what was happening.

After the authorities were notified, doctors and specialists were brought in from the capital of Liberia, Monrovia.

Charlie K4SKI had maintained an on-the-air relationship with those involved with the emergency, and he broke in to see if he could help. Dave mentioned that he and other members of the hospital unit wanted to let their friends and relatives in the United States know what was happening. Dave then started running phone patches through Charlie, who was located in Greenville, North Carolina.

K4SKI's log showed the following chronology of the traffic he ran for the hams in Liberia for the next 5 days:

April 2, at 2150 GMT, I ran 3 phone patches over 20 meters to relations in the U.S. to let them know what was happening in Zorzor. April 4, EL2CI, Doc (Dr. Gadegbeku) and EL2CG (Bruce) were on 20 meters talking about the epidemic. On April 5, Bruce had me run patches to the Communicable Disease Center in Atlanta, Georgia. These patches were run between doctors in Zorzor and doctors at the Atlanta center. They lasted 2½ hours. The next day, similar patches were run between the doctors in both countries. I was told that the Communicable Disease Center in Atlanta had a ham station (WB4GFE) and that they would try to have it on the air on 15 meters for us the next day. April 7, I looked for WB4GFE on 15 meters at 1710 GMT, and barely could make them out. KP4DLW joined in to help with a relay between us. Realizing that it was a cumbersome situation, I told the disease center that we would run patches with them via 20 meters.

The Lassa fever episode struck nine people in Zorzor and killed four of them. Of the survivors, two became deaf.

One of those who died was an American nurse, Miss Esther Bacon of Hawarden, Iowa. She had given 30 years and her life for humanity.

Dave Urfer became a knight not solely because of his own action, but because of the responses of several amateur radio operators who spanned two continents.

Join 'em!

More times than I'd care to count, amateur friends have remarked to me, "Your husband is so lucky to have you share an interest in our hobby," or, "I wish my wife could meet you so that you could tell her about ham radio and get her interested," or "How can I get my wife interested in ham radio – how did you get into it?" So, I thought I'd make an attempt to answer these questions in a way that can be helpful to those wives whose husbands would like their company!

Ham radio is a relaxing hobby to most people. Your man comes home and settles down in front of his radio and unwinds in a variety of ways – by telling somebody about the frustrations of the day, how lousy the Massachusetts drivers are, how bad the traffic was, etc. Or he finds some excitement in chasing some rather rare station halfway across the world, while his wife is wrestling with the pots and pans upstairs. At any rate, for numerous reasons, he enjoys the hobby. Perhaps he enjoys it so much that you find it difficult to tear him away long enough to get his attention. Aha! When various diversions fail to work, you can always adhere to the old adage, "If you can't lick 'em, join 'em."

All kidding aside, if you think about it, our life-styles seem to separate families a lot more than they should for the health of the family. Everybody is so busy doing his own thing that we lose sight of the most important aspect of life – our re-

lationships with those we love. In my view, anything that a woman can do to increase the amount of time shared with her husband is bound to improve their relationship. This doesn't have to be a great deal of time, but the knowledge that you care enough to make the effort can mean a lot. Nobody expects you to be an expert on subjects electronic. I pretend to no one that I am interested in the technical side of the hobby, though I've absorbed enough to have a very basic understanding.

Is it hard to pass the licensing exam? If you managed to learn to drive, you can do the same with ham radio. However, it *is* easier if you attend a class with competent instructors, rather than trying to muddle through the license manual on your own. Learning the code is simply a matter of concentration and determination. It doesn't take any great genius.

Besides improving family solidarity, I've made an awful lot of friends and met many people that I would never have met without ham radio. And ham radio is probably the most democratic hobby I know of. You are judged by the signal you put on the air and by your manners, not by how much money you have or have spent on equipment, not by your job or by your education. After listening to several hundred people going back and forth to work on a daily basis, it crosses most people's minds (or I hope it does) that they are just like you in the place where it counts, with all the externals that we like to put up around ourselves stripped away by the limitations of the airwaves.

My children have become involved in the hobby because they see the enjoyment their parents get from it. We have all come to depend on 2 meter FM as an adjunct to the phone and other modes of communications in keeping us in touch with each other and as an aid in times of emergency. Having a ham radio license has very practical advantages, as I have discovered on several occasions when my car broke down. I had help each time within minutes, and this is very comforting when you are at the mercy of an unpredictable machine.

For whatever reason you find most appealing, amateur radio is a hobby well worth the effort to become a part of, and which you can pick up at any time and *enjoy*.

Applying ATV

The technology to economically apply interactive television to educational purposes is here. It is based on the techniques being utilized in amateur television — ATV for short. Amateur television is an upgraded offshoot of ham radio, using a television transmitter, a TV camera, and a regular TV set with a special converter attachment. It allows an operator to broadcast a television picture and voice to another ATV operator. Through the use of a repeater on UHF frequency, it is possible for schools and other educational institutions to apply this technology — within a 15 to 150 mile radius — for educational purposes. The potentials are endless, ranging from use in traditional classroom activity to continuing and extension education. It can be used for homebound instruction, for seminars among experts at different universities in New York and as far away as Philadelphia, for a variety of community services (including linking a classroom with other segments of the community), and to provide educational services when severe weather and fuel shortages force school closings.

In order to insure that in the public interest certain frequencies within the UHF channels be allotted specifically to educational purposes, the City University of New York Graduate School, through its Center for Advanced Study in Education, and the nonprofit Communicasting Association of America, has filed a petition (1/21/77) with the Federal Communications Commission for the establishment of a new educational radio service, to be known as "communicasting" — i.e., the use of co-channel multi-lateral communication to educate and enlighten the participants as well as a listening/viewing audience. The use of radio repeaters, whose value has been proven in the land mobile and amateur radio services, is cited as the most cost-effective way to blanket an urban, suburban, or rural area with audio and television signals. Spectrum space is being requested in the 470 and 930 MHz range with preference being given to the use of television channels 70 through 83 (806-890 MHz).

The Graduate School's Center for Advanced Study in Education, through its Institute for Research and Development in Occupational Education (IRDOE), is currently engaged in pilot research and development activities surrounding curriculum development and delivery systems, evaluation of protocol approaches as they would apply to airborne transmission, protocols for interaction in multiple-station situations, and assessment of delivery ranges over various terrains and distances via both direct and repeater transmissions. It is anticipated that this research will have a direct bearing upon initial efforts to demonstrate airborne delivery systems for educational purposes in New York State.

Dr. Lee Cohen, Director of IRDOE, believes that the utilization of new technology is imperative if education is to remain viable in the current and future economic and social climate. "In addition to the ability to deliver education in a more cost-effective manner, we have the potential to serve additional populations not heretofore served and to provide lifelong learning opportunities to those who cannot avail themselves of the traditional classroom learning opportunities. We are on the cutting edge of something we cannot totally envision as yet, since application of the technology is only limited by educators' imagination and inventiveness." Interactive television, he quickly adds, "is not the one-way broadcast TV we've come to know, which limits learning to the lecture mode. Given the same considerations as have been provided to the Citizens Radio Service, for example, educational agencies properly licensed could experiment with the delivery of quality education, health, and social information, and enable viewers to question, challenge, and even present their accomplishments for grading purposes over the airwaves. For the FCC to deny education on these frequencies and, at the same time, expand non-essential mobile and fixed station operations, is to reject the populace in favor of the few."

City University of NY
New York NY

The Key

In the world of business and industry, there's an adage which states that when your boss asks you to give up your key to the executive men's room, you're in deep trouble.

Looking closely at the recent decisions by the FCC affecting the amateur radio service, I can't help but wonder if we hams aren't being asked to turn over our keys. And, if so, just how much trouble are we in?

It's called "deregulation," and over the past few years it has meant the elimination of log books, the closing of many official monitoring stations, the abolition of the requirement to identify portable and mobile operations, and so forth. To be certain, they are all seemingly small things, but hidden among them may lurk a more sinister meaning.

On the surface at least, the FCC has said that since we're doing such a great job of policing and regulating ourselves, there's no need for government to become involved. This is great; I'm for less government. But in light of the bucket of worms in which the FCC finds itself as a result of the snowballing CB service, I can't help but be a little skeptical about the FCC's rationale.

Over the years, the history of amateur radio has been one of compliance with regulations and courtesy in operation. They have become our hallmarks. In short, we have been a most disciplined group. Discipline can be effected in one of two ways: First, we do something because we know an enforcer is looking over our shoulders. Or second, we act for the common good. The latter is certainly the ideal situation, but, alas, it is also the more utopian of the two. Thus we're left with the first type of motivation.

In the 1920s, the early days of radio, chaos reigned supreme. A regulatory agency was desired and necessary. It was created, and with supervision, guidance, and enforcement came order — law and order, if you will, as opposed to the law of the jungle. We learned that according to a regulation, something had to be done in a certain manner, and then we came to appreciate the need for doing it just that way in the first place. One notion complemented the other. And most of us grew up in amateur radio with this concept. Take away the concept and the prospects are frightening.

Amateur radio is growing. It is not growing perhaps quite as rapidly or as extensively as some may envision, but it is growing nevertheless. If new members join our group who have never been exposed to the tight discipline under which we've operated all these years, how will they behave? How can they be expected to behave? They will probably act in much the

same fashion as the spoiled child who wants something done his way at the particular time he wants it, knowing full well that the threat of a spanking doesn't exist because there is no one there to administer the punishment.

Personally, I have always felt that there should only be just enough federal government to insure that the things which have to be done in a democracy get done. The FCC's abdication of its role in the amateur service can, over the long run, pose a very real threat to the existence of amateur radio itself. Consider another adage: "Out of sight, out of mind." I doubt whether we as a group are sufficiently strong enough to (a) police ourselves entirely, (b) look out for our interests in international frequency allocation conferences, and (c) protect ourselves against the interests of powerful electronics manufacturers' lobbies when they threaten us.

In short, we still need the FCC. If deregulation is coming about because amateur radio has in fact matured to the point where strict supervision and guidance are no longer necessary, then it should be continued on a slow basis and explained very thoroughly. On the other hand, if deregulation is only an excuse for the FCC's inability to govern all the radio services within its purview, then we are in deep trouble indeed.

Hopefully, in future decisions affecting the amateur service, the FCC will act judiciously and cautiously, and certainly not give the appearance of the boss coming into your office and asking for your key.

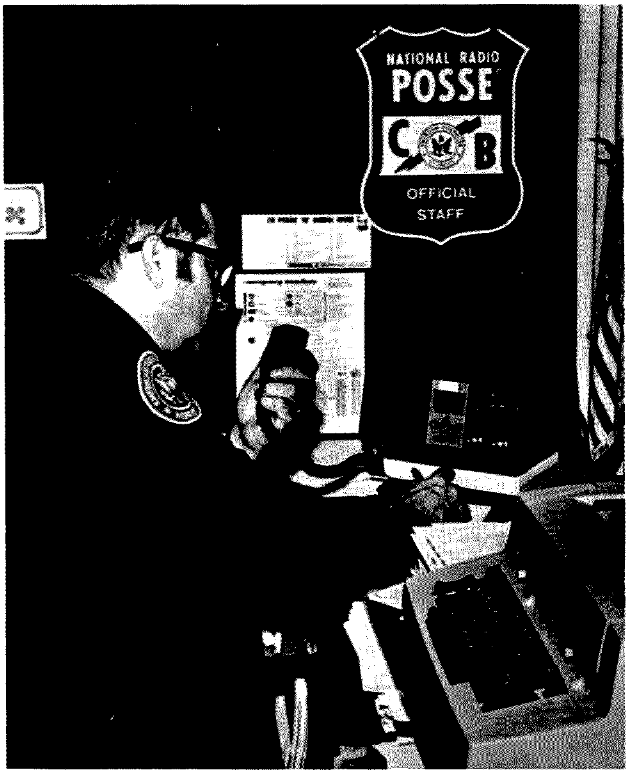
The Posse

There has been much discussion on these pages in recent months about the "HFers" and the consequences of the RFI/TVI problem. (See "The Ban Moves Closer" and "C'mone Texas Salt Rat . . ." in April and March 73, respectively.) There is, like any other issue, another side to the story. So, in the same vein as "CB Can Do Some Things Better" in our March issue, here is more testimony to the usefulness of Citizens Band. — Ed.



Capt. Gerald S. Arenberg, CB Posse Training Officer, is shown at the monitor at the National Headquarters.

With some twenty million Citizens Band radios, the "eyes and ears" of local police are driving criminals off the streets and into jail. Drunk drivers are being spotted and reckless drivers are being reported to "Smokey the Bear" by the Citizens Band operators. Why? The answer, claims Chief of Police Robert Ferguson, president of the National CB Radio Posse, is very simple. "We monitor emergency channel 9 like many police, sheriffs, and state patrols. People are tired of the drunks that are running up auto insurance bills, the reckless driver who may kill or maim your friends or mine. 'Smokey' is now as close as your CB radio and you can get help quickly. With CB you don't get involved. You report what you see and the police act on your information."

The National CB Radio Posse was the brainchild of Chief Ferguson, whose department is located at a major crossroad near Akron, Ohio, in Bath Township. "There are not enough police to cover every street and highway. So a lot of good people feel it's time they made the streets safe again. They are reporting crimes as they happen. We are able to send aid to motorists quickly because of reports by CB radio to our station. Lives are being saved. Criminals are being caught and jailed, all because a man or woman picks up the 'mike' and calls on the emergency channel (9). The CB Posse got started because some CBers wanted to do a bit more by organizing into community radio patrols. We encouraged this because we and thousands of other police and sheriff's departments can use trained eyes and ears.

"In our case, we designed an emblem to wear, a metal shield, car tag, and asked for volunteers throughout the nation to carry first aid kits, flares, warning flags, a flashlight, and other equipment. These are items that everyone should carry as a safety rule, anyway. The CB Posse member is not a police officer. His or her role is to use the radio, patrol, and aid a motorist or request aid be sent. In one southern city, 1900 calls were logged in one month, resulting in the arrest of a rapist, a burglar, a number of armed robbers, a murderer, and many rescue missions to distressed motorists.

"Like the Marines, the National CB Radio Posse is looking for a few good men and women who want to help via radio as unpaid eyes and ears for their own community police. Our program is a national one. We have chapters springing up in many parts of the nation. We have chartered the National CB Posse as a nonprofit fraternal organization with modest dues for benefits and services provided members — everything from a special ID card and emblem to a death benefit if a member is killed while assisting any police officer or fire fighter."

Hamming/G5

If you want to "ham it up" in England when visiting, "plan ahead" to take advantage of the reciprocal licensing procedure available. Remember, there is nothing to listen to on what we most popularly use: 146 MHz. It takes a little time to get it (license), so start early and surely allow more than a month. Airmail your request to: Home Office, Radio Regulatory Department, Radio Regulatory Division, Licensing Branch (Amateur and Special), Waterloo Bridge House, Waterloo Road, London, SW1 8UA, England.

There are eight different classes of licenses available. Four are for fixed stations, four are for mobile stations.

Most commonly, a reciprocal license is granted for six months. After expiration, the callsign is reserved for your use for any UK license granted you in the future. Some of the regs are quite different — no other person may speak over your rig, no third party traffic, no code speed over 20 wpm—and no equipment capable of transmitting on CB frequencies (similar to ours) can be taken into the country without advance permission.

As noted before, frequency allocation is different — their two meter band is from 144 to 146, with 11 specific frequencies between 144 and 145 that *must* be avoided. 150 Watts is the maximum input power. FM is between 145 and 146.

A copy of your license must be enclosed with your application for the British license; don't send any money until you are advised of your application being accepted — at that time they'll tell you what to send. In December, 1976, the fee for a fixed station license was about $10; for a mobile station license it was $5. You can buy British currency at a large bank and send it, saving the cost of international money orders ($3 or more).

New Products

THE HEATH HW-101 TRANSCEIVER

With all the growth we've been seeing in the amateur ranks, we thought it might be time to look over some of the less expensive ways to get on the air. Outside of home brewing a transmitter from a battered old TV set and using a bargain basement receiver (as many of us did years ago), we thought we'd examine some middle ground – the kit transceiver. The choices are pretty narrow, especially when economy is the major concern, so here's what the editors have come up with – the Heath HW-101. As our reviewer points out, the HW-101 has been around long enough, and enough hams have been using it satisfactorily, to put the Heath well up the ladder on anybody's list of choices. Having used HW-101s of various vintages in situations from field day to emergency operations, we can testify to the transceiver's reliability and simplicity. – Ed.

The HW-101 is by far the best buy for the ham who wants a five band SSB and CW transceiver. With 180 Watts input and 125 Watts output on 75 and 40 meters, and 90 Watts out on the higher frequencies, the Heath is perfect for the seasoned amateur or a Novice or Technician with hopes of upgrading to a higher class license. I decided on the HW-101, after a long absence from "the low bands," because of economy (list price is $339.00 plus ac supply) and reliability. There are thousands of these rigs operating all over the world.

From date of order, it only took 10 days for the kit to arrive. I was pleasantly surprised to see my new Heath come in such a compact carton. Those Heath engineers must spend countless hours planning every last detail. Heathkits (for those of you who have never built one) use an ingenious system of subpacks. Gone are the days of a kit being just instructions and a carton full of miscellaneous parts. (The HW-101 had 10 subpacks.) During the process of building the kit, a subpack is called for as it is needed. I'll bet this has saved many a call to Benton Harbor from frantic kit builders who have almost completed their projects only to find a diode or transistor has been sucked up by the XYL's vacuum cleaner or eaten by the family Labrador retriever. Essentially, what this system does is provide only the parts necessary for the phase of construction on the bench at the time. No sorting through muffin pans full of parts.

After opening the carton (and looking at the empty Heath green cabinet and dreaming of DX on 20m), I saw that the hams at Heath had sent me a little note explaining that they had received a bad batch of 6HS6 tubes. They enclosed 6AU6s as substitutes, and all I had to do was fill in my name and address on a postcard they enclosed, so the proper tubes could be shipped as soon as Heath received them from the manufacturer. The tubes had not arrived as of this writing, but the 6AU6s work just great, with just slightly reduced receiver sensitivity.

The 200+ page manual is well illustrated and easy to follow. It includes chassis layouts, voltage and resistance charts, x-ray views, and schematics. In addition to the troubleshooting charts, the manual has many foldouts that give parts locations for construction. After reading through the manual, I started putting my new radio together. The first steps Heath outlines are the installation of parts on the switching boards. These are special circuit boards with built-in wafer switches to help eliminate intricate switch wiring. This is a good place to start since the components are not spaced extremely close together. That kind of a start gives the first-time kit builder a good chance to check out his soldering paraphernalia. I was somewhat surprised to see that Heath did not use glass-epoxy circuit boards. But, judging from the number of HW-101s on the air, I would venture to say that the composition of their boards is more than adequate. What could have been a very tedious part of the construction was already done for me at the Heath plant, namely, the construction of the wiring harness. This harness contains all the necessary wires and cables that run between the circuit boards. It certainly was nice having those multi-color coded wires neatly arranged and prepared. It really saved me quite a few headaches.

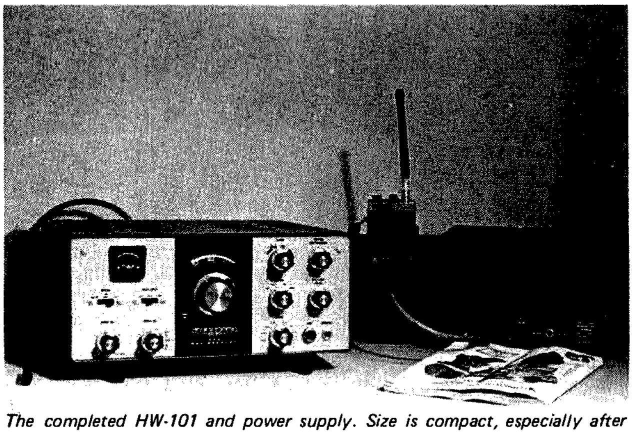
The kit went together amazingly well, although it is not advisable to spend really long stints at the work bench doing such precise work. I found that evenings after dinner I could work for a couple of hours without experiencing too much lower back pain. One evening I worked on the HW-101 for over six hours, with only one fifteen minute break. This is when the only wiring error that I made occurred. But, it *was* avoidable. If I hadn't been in such an all-fired rush to get the rig completed and on the air, it probably would not have happened. A slight amount of patience is a virtue when constructing anything, be it a home brew keyer or a model airplane. My only words of advice are, when you're building a kit and your body tells you it's time for a break, listen to it and take one! Heath's manuals are so well thought out that you can stop virtually anywhere during construction, and have no problems at all picking up where you left off. A couple of times during construction, I had to run off to emergencies (I am a volunteer firefighter up here in New Hampshire). But, despite the interruptions, I had no problem returning to the kit. Another thing that Heath has nailed down is what I call the "boredom factor." In other words, they know just when a certain portion of construction may become tedious, and before you get there, they'll have you go to another section of the kit.

The HW-101 went together in just under 60 hours (including 3 or 4 hours for alignment). After completing the transceiver, I moved on to the matching HP-23B power supply. This popular supply, which has powered all kinds of amateur equipment in addition to the Heath units it's made for, provides the operating voltages necessary for fixed station operation. It seems very well filtered, and went together in a couple of hours.

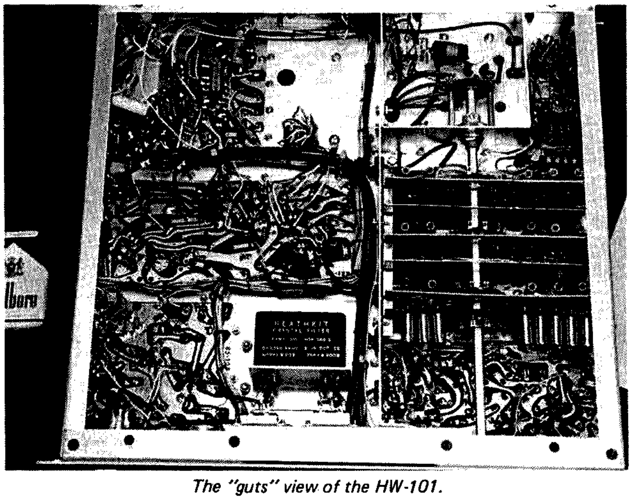
Alignment of the HW-101 is very simple, and can be completed without thousands of dollars worth of test equipment. Actually, all that is required is a VTVM and Heath's trusty alignment tool (which is included with the kit). I thought that the VFO alignment might be a little tricky, but it really wasn't at all. During alignment of the VFO, I found that the frequency counter on WA1UNN's test bench was quite handy for initially determining the VFO's frequency. Heath does give you a method of using another receiver to hear the VFO's output, so a counter is not essential. The remaining alignment is very simple and straightforward. The built-in crystal calibrator is used as a signal source and the S-meter as a peaking meter. We got the receiver section alignment completed and connected the unit to a dummy load. Now for the infamous "smoke test."

I turned the mode switch to tune and, uh-oh . . . nothing! Well, not quite, but the output was very low. I turned the unit off and mumbled something about Murphy showing up on schedule. Then I took the unit home and went over all the step-by-step instructions, but could not find any wiring errors. Now what? As the manual suggested, I had another pair of eyes look at it. Rich WB1ASL found the problem in less than an hour. I had placed one lead (from a resistor on the driver circuit) in the wrong hole on the circuit board, and it ended up to ground instead of going to the rest of the circuit like it was supposed to. If I had only been a little less anxious, this minor error would not have happened. Well, anyway, the rig fired up just great after correcting the wiring error, and the rest of the alignment procedure was completed.

At home I had raised a 500-foot longwire antenna, and had no idea how the swr would stack up. I got home just in time to listen in on the first weekend of the ARRL DX contest. The swr on 15 meters was about 3 to 1. The Heath pi-network output section took it right in stride and fired right up. Had I been using transistors instead of tubes in the final, such a match would have been impossible.



The completed HW-101 and power supply. Size is compact, especially after locating the supply in Heath's matching speaker (not illustrated).



The "guts" view of the HW-101.

One of my first contacts was with Len W8LF in Senegal! Since then, I have received many excellent reports from stations all over the country and the world, with high marks for audio quality. The performance of the HW-101 has been more than satisfactory.

For CW operation, I later added the optional 400 Hz filter. It really makes the weak ones come right up out of the mud. It's good and sharp, yet not so sharp as to cause any annoying ringing. Break-in on CW is accomplished by operating VOX from a keyed tone, which works out quite well. Those of you who are high speed CW ops may want the VOX delay set in a position that facilitates quicker receiver recovery. That position may not be best for VOX operation on voice, but it is no problem to quickly readjust the VOX delay (since all VOX controls are mounted on the right-hand side of the transceiver and are easily adjusted without any cover or cabinet removal). Located nearby are the S-meter zero control and bias adjustment.

Although the HW-101's dial readout is only in 5 kHz increments, the receiver has plenty of selectivity and bandspread. This is evident on SSB, due to a 2.1 kHz crystal filter and the fact that it takes 35 turns of the large tuning knob to go from one end of the band to the other. I found the tuning to be surprisingly smooth, without any discernible backlash. After about a 20 minute warm-up period, the rig seems to be very stable. No measurable drift could be detected after warm-up.

Transmitter tune-up is simple – the preselector is tuned for maximum received signal at the desired operating frequency. This also sets up the transmitter driver tuned circuits to the approximate peak position. The final tune and loading controls are then tuned for maximum output. The mic/CW level is then turned up to maximum output, and you're all set. The meter switch may then be moved to the plate position to check for proper plate current.

The front panel controls are laid out well. In the receive mode, there is metering of signal strength. While in transmit alc, plate current or relative output may be monitored. The dial and meter are both backlit for easy readability.

The HW-101 is quite a rig to build on. I'm looking forward to constructing the mobile power supply and trying my luck while on a camping trip this summer. Also in the works are modifications for working RTTY. There is plenty of output to drive any linear amplifier on the market today, and the front panel level control is quite handy for this purpose.

I'd like to say that, in these inflationary days, I agree with Heath that the HW-101's price/performance ratio is an exceptional value. *Heath Company, Benton Harbor MI 49022.*

73 TESTS THE TUNERS

We began this series back in March with the idea of covering as many antenna tuners as possible. Our staff has gotten to the point where they almost cringe with each new arrival, but you'd be hard-pressed to find one of us operating without one these days. To a man, we've all discovered the advantages – greater efficiency, reduced TVI, and cooler running finals. In future months we'll be looking at some of the less expensive tuners ($40 price class), and hope to finish up with a look at some home brew versions. So read on, and keep us posted on what gear you'd like us to test for you!

DENTRON 1 KW SUPERTUNER

In the middle ground between the $59.50 Dentron 80-10 Skymatcher random wire tuner (see the March *73*) and the $299.50 Monitor tuner (see April) lies the area where most amateurs hang their hats. If you live in an apartment or move a great deal, the random wire is your best antenna bet. On the other hand, if you run a full gallon all the time and are one of those people who go through long periods without food or rest to catch that rare DX, the super-duper model is probably what you need.

In a recent *73* survey, we found that the average amateur is on the air 8-10 hours a week, runs between 200-500 Watts, and budgets a few hundred dollars a year toward updating the shack. "Average" ham, meet the Dentron 1 kW SuperTuner! Retailing at $129.50, this unit is the perfect way to solve all of your matching problems without blowing your entire equipment budget in one fell swoop.

The SuperTuner is set up for just about any matching situation that you'll run into. A quick glance at the back panel shows sturdy screw terminals for balanced, unbalanced, and single-wire feed. An SO-239 for the more conventional antenna setup is also provided. The front panel features three controls for transmitter matching, inductance, and antenna matching. Tuning the unit is simplicity itself, using either an swr bridge or transmitter output meter. I had no problems perfectly matching a random wire, a standard dipole, and a beam. No worry about those finals going up in a puff of smoke either.

see page 188

The SuperTuner is compact enough to fit easily in any shack, but it's still solidly built. After taking out all the screws necessary to expose the guts, I found the unit well laid out, with heavy-duty components used throughout.

The Dentron SuperTuner covers the entire range of 160-10 meters. For the sideband gallon crowd, it's also available with the capability of handling 3 kW at $229.50. *Dentron Radio Company, Incorporated, 2100 Enterprise Parkway, Twinsburg OH 44087.*

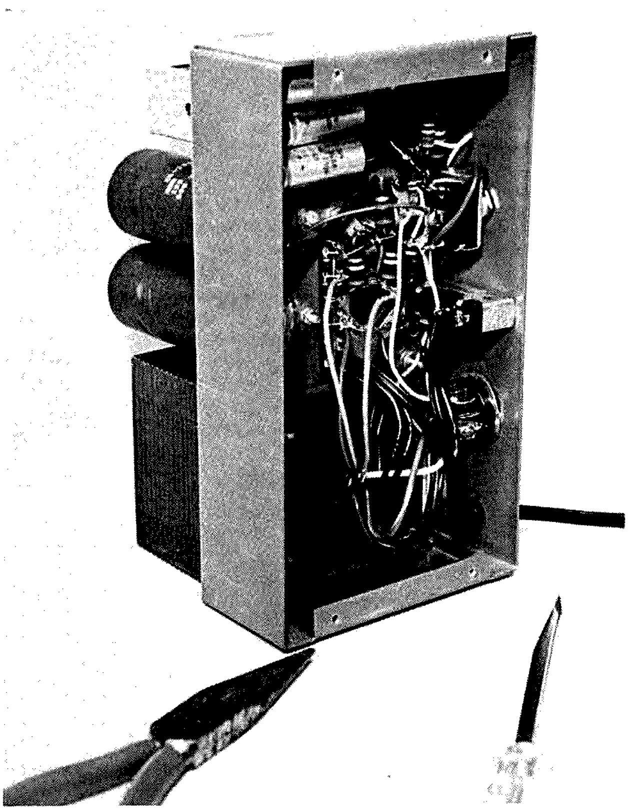
73 TESTS THE COMMUNICATIONS RECEIVERS

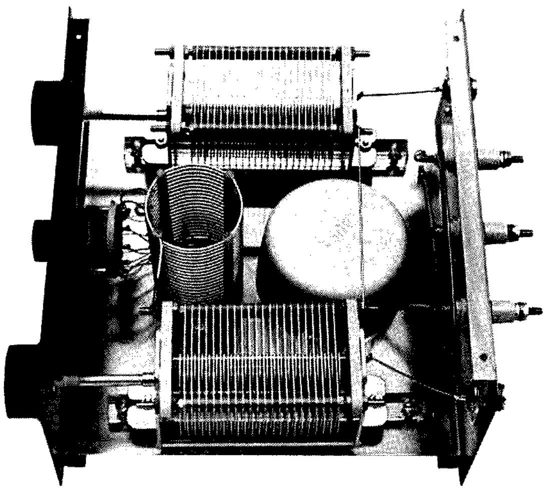
We continue this month with our series on general coverage receivers. Plans call for us to include some smaller, portable sets in future issues, along with the communications units we started off with. As one reader pointed out in a recent letter, SWLing is an integral part of ham radio in many foreign countries, where the prospective ham is required to confirm a specific number of countries before moving on to an amateur exam.

YAESU FRG-7 COMMUNICATIONS RECEIVER

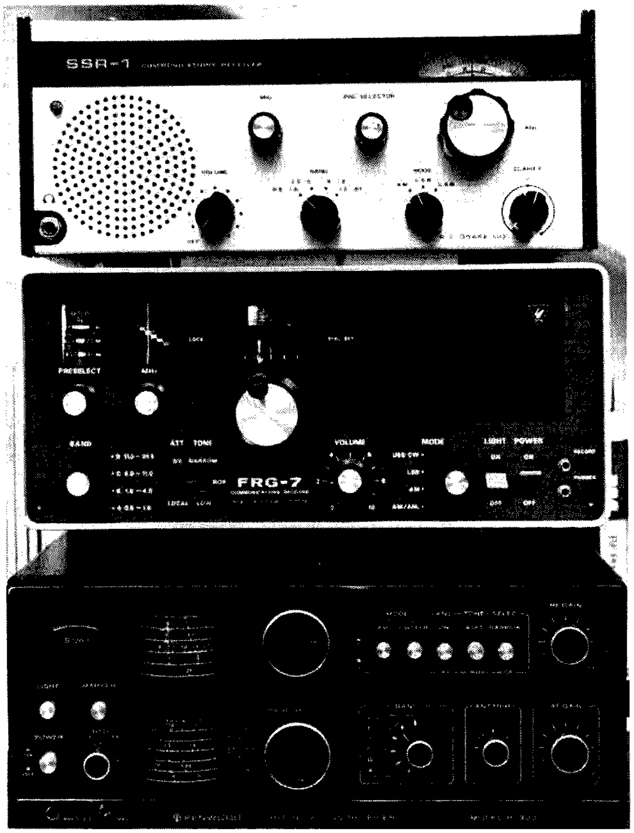
My first real exposure to the world of communications receivers occurred many years ago, a few weeks before Christmas. I had just obtained a new WN8 call, and was ready to tackle the



The matching HP-23B ac power supply.



The SuperTuner interior view – a lot in a small package.



Several of the general coverage receivers undergoing testing by 73 staffers.

Novice bands. A search through greater Cleveland's ham emporiums unearthed a vintage Hammarlund HQ-129X general coverage receiver that served me well for quite awhile. However, as with most receivers of yesteryear (and of more recent days), there were several problems.

General coverage receivers have always been plagued with problems that result when a device is designed to satisfy the requirements of many. Tuning accuracy and stability are adequate for SWL use, but marginal for amateur use in bands overloaded with QRM. BFOs are optional on some general coverage receivers, rendering them ineffective for SSB and CW use. Many hams avoid general receivers for the simple reason that "bandspread," or the capability of stretching a small band segment over many revolutions of the tuning dial, is lacking.

I still have my classic Hammarlund, even though it is so unstable that I cannot accurately copy the evening RTTY bulletin on wide shift. However, a whole new breed of general coverage communications has recently arrived on the scene, filling a gap several years wide left when few radio manufacturers were paying attention to the SWL and general listening community. Recently, I was fortunate enough to obtain one of the newest and most technically advanced receivers to test, the FRG-7, manufactured by Yaesu.

My first reaction to the receiver was one of surprise when I picked up the box. Amazing! I could lift it and carry it with ease. It is totally solid state, and its design is based on the latest advances in digital technology. The tuning scheme is based on the phase locked loop frequency synthesis technique, which eliminates the dial inaccuracies characteristic of older communications receivers. It works as follows: The user selects the single megahertz band he desires to tune. This is accomplished by rotating a knob that turns a drum calibrated from zero to 29 (MHz). An LED indicator lamp next to the MHz control remains illuminated until the synthesizer "locks" on the desired megahertz band. When the LED goes out, the FRG-7 is locked into calibration, allowing perfect main dial accuracy. The main dial is calibrated from zero to 1000, and is covered by 10 full turns of the backlash-free tuning control. Resolution of 5 kHz is easily possible by splitting the eighth-inch dial divisions. The best part of the tuning scheme is, however, the fact that the same accuracy is provided for each MHz range. For the first time, an SWL can search for that elusive foreign broadcast station knowing he is on frequency, and the ham can use the main tuning control as a bandspread, due to the one MHz per band feature of the FRG-7. A "dial set" adjustment is provided to accommodate mechanical wear of the main dial components. A calibrated antenna preselector control is provided, and normally must be peaked several times while tuning across a one MHz segment. An rf attenuator is also provided, calibrated "normal," "DX," and "local." I found the "normal"

The Yaesu FRG-7 communications receiver, with some QSLs familiar to SWLs everywhere.

setting to be adequate for all listening, as no receiver overload was experienced while testing the radio. The remaining front panel controls consist of a volume control, a three-position "tone" control, a mode switch, and two toggle switches. The latter switches control power and panel lamp illumination. The panel lamp switch is necessary, as the FRG-7 may be powered by an internal battery, consisting of eight "D" flashlight cells, rendering the receiver perfect for weekend trips. A front panel speaker is provided, as well as an earphone jack and recorder jack. The receiver is logically organized, and it only took a few moments to switch bands once the MHz switch and main tuning dial were mastered.

Operating the FRG-7 is a pleasure. I have always enjoyed SWLing, even though it has been a few years since I sat down and actively chased foreign broadcast stations. The tuning scheme is remarkably accurate, and all the stations appeared on the dial exactly as they were listed – no 5 kHz fudge factor as with non-synthesized communications receivers. The FRG-7 should appeal to the avid SWLer or broadcast DX hound for that reason. Sensitivity is good on all bands, and only an occasional tweaking of the antenna preselector was necessary to bring 'em out of the noise. (The antenna used for the SWL sessions was a 350' longwire.) The mode control has positions for AM, AM with noise limiting, LSB, and CW/USB. Each functioned correctly.

Performance on the ham bands was as expected for a receiver in the FRG's class. The "wide" main tuning dial effectively doubles as a bandspread control, and there was no difficulty copying stations on the low bands. Sideband reception was excellent, and it was strange not using a BFO control to tune them, as is common practice with older communications receivers. However, it was difficult to sort them out during the pileups on contest weekends. A "clarifier" control would have been a nice feature for SSB reception, but then again, the FRG-7 was not designed as an amateur receiver. In my opinion, the FRG-7 would make a fine Novice receiver, or a "second" receiver for the seasoned amateur. In any case, it's a perfect rig for vacation and weekend trip use. The battery pack makes it usable even in remote cabins, or onboard a boat.

The FRG-7 has three antenna connectors, a ground, and a muting connector on the rear panel. The broadcast band requires a separate antenna, and both a clip-type and standard SO-239 coax connectors are provided for high frequency use.

The Yaesu FRG-7 is definitely a big improvement over my old Hammarlund workhorse receiver. Its performance is definitely "ham standard" in the areas of accuracy and sensitivity. Its price and versatility, as well as portability, make it an ideal SWL receiver. At *73* we even used the FRG-7 as the low i-f receiver for tuning up a 432 MHz converter destined for EME use. No problems were encountered, and the battery power sure beat running a fifty-foot extension cord which would have been required for other receivers. For those of you needing a second receiver with state-of-the-art features, it would pay to consider the Yaesu FRG-7. Who knows – you might end up retiring your present receiver! *Yaesu Electronics Corp., 15954 Downey Ave., Paramount CA.*

MFJ 1030BX RECEIVER PRESELECTOR

Recognizing that most receivers are perfectly adequate on frequencies below 10 MHz, MFJ Enterprises has designed its new model 1030BX preselector to cover 10 to 30 MHz, where many receivers, particularly the older and less expensive sets, do fall short on performance.

Using a protected dual-gate MOSFET for extremely low noise, the unit has excellent strong signal handling ability and easily meets the manufacturer's claim of providing a typical increase in gain of 25 dB.

Although a bit more expensive, the 1030BX uses separate input and output tuning controls to provide maximum gain and selectivity while eliminating the tracking problem of a dual-gang capacitor.

The two high-Q double-tuned circuits provide a real improvement in weak signal reception while significantly reducing out-of-band signals and images. With the preselector on and properly "tweaked," you can cut back on the receiver's gain, reducing receiver cross modulation and overload problems while maintaining an excellent signal to noise ratio and the ability to pull out the weak ones.

Using the model 1030BX with a Radio Shack DX-160, a World War II vintage BC-348, and a Barlow-Wadley XCR-30 resulted in a significant improvement in performance in each instance. In fact, at one midtown New York City location, the preselector made the difference between useful reception and a total wipeout. The MFJ 1030BX preselector can be highly recommended to both amateurs and SWLs seeking to improve the performance of their receivers.

Packaged in an attractive Ten-Tec enclosure measuring 2-1/8 by 3-5/8 by 5-9/16 inches, the model 1030BX receiver preselector sells for $49.95. Unconditionally guaranteed for one year, the preselector is available from dealers or direct from *MFJ Enterprises, PO Box 494, Mississippi State MS 39762.*

MICROWAVE ASSOCIATES "GUNNPLEXER" 10 GHz AMATEUR TRANSCEIVER FRONT END

Microwave Associates of Burlington, Mass., has introduced a microwave transceiver "front end," designed specifically for amateur use. The MA-87127 Gunnplexer is an electronically tunable, frequency modulated oscillator operating in the amateur 10.0 to 10.5 GHz band. The oscillator produces about 20 mW of microwave energy directly from a 10 volt supply. A Gunn diode is used in the oscillator, and a portion of the energy is used to provide injection for a receiver mixer diode. The oscillator and receiver are isolated by a special ferrite circulator. The oscillator may be frequency modulated by applying voltage to a varactor diode included with the rf head. The Gunnplexer has a mechanical tuning range of about 100 MHz, and may be electrically deviated over a 60 MHz range.

In order to use the Gunnplexer as a communications device, the user must provide an i-f receiver and modulating source. The i-f range is customer selectable at time of purchase, and is typically in the range of 30-200 MHz. A standard broadcast FM receiver may be used as an i-f receiver for experimental applications. Microwave Associates claims that a communications range of up to 100 miles can be achieved with two Gunnplexers under optimum conditions. A narrow (10 kHz) i-f is required for such DX communications.

The microwave devices are not limited to communication applications, however. A Doppler effect radar transceiver can be built using a single Gunnplexer, based upon application information available from the manufacturer. Options for the Gunnplexer presently consist of a gain horn antenna that bolts to the rf head.

The *73* staff has recently obtained two Gunnplexers. A complete communication system is being developed employing a phase locked control circuit. Watch *73* for complete details as the system is refined. Preliminary tests indicate, however, that the Gunnplexers perform as advertised. These devices should eventually interest repeater owners, as the potential for a troublefree, wireless link is definitely attractive.

The following are available from Microwave Associates: MA-87108—Gunn Oscillator and Varactor, $60; MA-87127—Complete Transceiver, $85; MA-87140—Complete Transceiver and Antenna, $108; MA-87141—Two Transceivers and Antennas, $180. *Microwave Associates, Inc., Burlington, Massachusetts, (617) 272-3000.*

THE HEATHKIT ET-3300 LABORATORY BREADBOARD

Breadboarding has traditionally been a necessary, but often tedious, part of amateur and professional electronic design. Although a number of methods of breadboarding exist, none has really made the job easier, only different. On the one hand, we find projects tacked together on little pieces of perfboard or some sort of "universal printed circuit stock." On the other hand, there are those who prototype their projects on little pieces of phenolic material equipped with any of several types of horrid little spring clips.

The first really convenient breakthrough in breadboarding techniques came a few years ago when several companies began to offer terminal blocks set up as DIP-IC sockets with several contacts bonded together on 0.1 inch centers required for IC mounting. The only problem with these for amateur use was that they are expensive, especially when purchased as a lab breadboard with internal power supplies.

I recently bought and assembled the Heathkit Model ET-3300 laboratory breadboard. Total assembly time was a little under four hours, and there were no hitches worthy of mention.

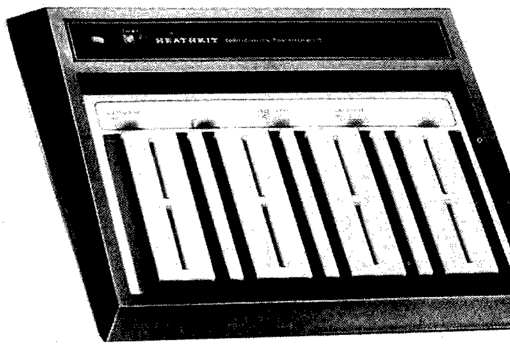
The ET-3300 has four solderless IC breadboarding sockets. Each socket has 48 rows of contact pairs on 0.1 inch centers, and will hold up 6 14-pin DIP ICs (24 total). There are also three common bus sockets that each have two rows of common terminals running the length of the socket.

To me the biggest attraction was the ET-3300's built-in power supplies. In the past, regular bench supplies were used and that meant alligator clip leads or solder-tacked power wires all over the place. Besides being clumsy and just plain unsightly, it also produced more than a few problems with hum pickup, ground loops (especially troublesome in rf or those logic circuits operating at high speed), and layout. These problems are reduced considerably and, in many cases, eliminated, by the socket designs and internal power supplies of the ET-3300.

There are actually three ground-referenced power supplies in the Heath breadboard. One is suited for TTL and other digital logic elements because it will provide up to 1.5 Amperes at +5 V dc. I personally feel that the 1.5 Ampere figure is a little high, because it is based on a heat sinked LM309 regulator, normally rated at 1.0 Ampere. Even though I have drawn 1.2 Amperes for about two hours, the device survived nicely. The remaining power supplies are +12 volt and -12 volt at 100 mA, and they will accommodate operational amplifiers, microprocessors, and certain linear (non-op amp) ICs. These supplies are regulated to within ±2% and the specs were found to be conservative on the model I tested. I noticed only a few millivolts difference in the 12 volt supplies as current was increased from 0 to 100 mA. These supplies are also current limited to prevent damage from the almost certain short circuits that will exist in breadboarding.

The cabinet design is easy to live with, and is suited to long breadboarding sessions with little fatigue. In other brands of breadboard (of similar design) I've used, the panel was either sloped too high or too low for comfortable use over a long session. The Heathkit version appears to have been designed by an engineer who has done extensive breadboard work using some of the same products I have dealt with. The others will tire out your forearm and wrists in much the same

see page 192



The Heathkit Laboratory Breadboard.

manner as an inappropriate or poorly designed telegraph key.

Two things annoy me about the ET-3300, although others may feel that they are too minor for comment. One of these is my old paranoia over fuses inside the case, where a simple fuse replacement is a major undertaking. The other is that those four IC sockets are not assembled at the factory. They ship the empty shells and a zillion multi-pin inserts. I spent the better part of a half hour inserting those little metal contacts into the shell. My personal feeling is that I would prefer to pay a little more and have that chore done at the factory by a machine. Of course, this kit only costs $79.95 ($120 assembled), so I guess it isn't too bad.

It is my judgment, based on several years of experience, that the Heathkit ET-3300 is well suited to industrial, commercial, and amateur breadboarding requirements for both IC and discrete designs. It will cut your breadboarding time considerably, but in my view that is only the icing on the cake. Its main attraction is that it facilitates flexible breadboarding procedures by allowing you to make changes rapidly – and that will reduce not only breadboarding time, but also the anxiety quotient. Of course, its most endearing quality is that it gives these advantages while forming a closer impedance match between the world's money supply and my bank account!

ANALOG COMPANDOR FOR NOISE REDUCTION IN COMMUNICATIONS AND AUDIO EQUIPMENT NOW AVAILABLE FROM SIGNETICS

A dual-gain control circuit which incorporates a complete compressor and expandor into one linear IC is now available from Signetics.

Designated the NE570/571 Compandor (compressor/expandor), the analog device is designed for applications in consumer communications equipment, including telephone subscriber or trunk carrier systems and hi-fi audio equipment.

In such applications, the compandor can be utilized as a means of reducing noise, as well as interference from other communications equipment, according to Neal Williams, Marketing Manager, Consumer Products, for Signetics' Analog Division.

Either channel of the dual-gain circuit can be used as a dynamic range compressor or expandor. Each channel has a full wave rectifier to detect the average value of a signal; a linearized, temperature-compensated variable gain cell; an operational amplifier; and a bias system.

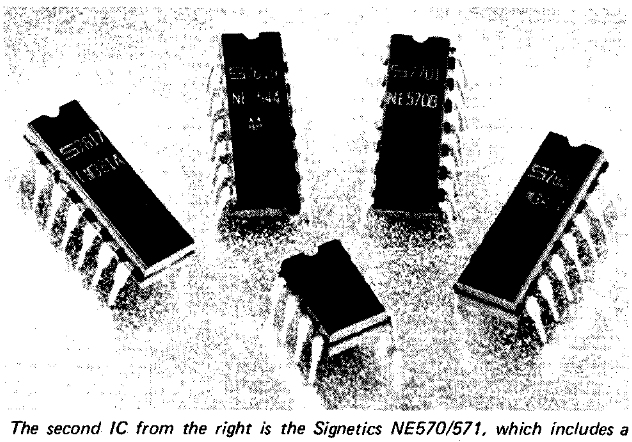
The arrangements of these blocks in the NE570/571 result in a circuit which can perform well with few external components and yet can be adapted to many diverse applications, according to Williams.

The new units are ideally suited for application as a telephone trunk or telephone subscriber N2 compandor which is fully compatible with the Bell System's low level tracking curve; as a high level fast attack limiter making possible small signal gain reduction by factor of 10; as highly flexible basic expandors or basic compressors, in which the size of input and output signals are adjustable; and as a "noise gate" which will mute the output when the input signal drops below -60 dBm.

The NE570/571 compandors are also useful for applications in similar dynamic noise reduction systems, in voltage controlled amplifiers, and in dynamic filters.

The compandor features a THD trim terminal in the circuit, which provides a means for trimming out offset voltages and thus trimming the distortion they produce.

Other features include operation down to a 6 V dc supply voltage (maximum rating is 16 V dc), a dynamic range of greater than 110 dB, maximum power dissipation of 400 mW, and an operating temperature range of -40° to +70°C. *Signetics, 811 East Arques Avenue, Sunnyvale CA 94086.*



The second IC from the right is the Signetics NE570/571, which includes a complete compressor and expandor in one chip. The rest of the ICs are also Signetics products.

JANEL LABORATORIES MODEL 01-A PRECISION CRYSTAL OSCILLATOR

Janel Laboratories has announced a new crystal oscillator capable of outstanding frequency stability. This new oscillator, Model 01-A, is ideal for counters, synthesizers, and communications systems, where it is possible to achieve about a 10 times improvement in temperature stability over commonly used TCXOs. The oscillator is available as a standard item for 10 and 4 MHz, and is therefore readily adaptable to most counters and other equipment. Adapter boards are available for lower frequencies such as 1 MHz or 100 kHz.

The 01-A oscillator features a proportional crystal oven that holds the crystal frequency within 2 Hz at 10 MHz, over an outside temperature range of -25 to +50°C. The rf output is TTL compatible, and only a single 12 volt power source is required. Self-contained voltage regulation provides immunity from changes in the supply voltage. The oscillator is much smaller than the usual oven oscillators – only 1-7/8 x 1-5/16 x 3/4 inches. Solder pins are provided for PC board mounting, or the unit can be mounted to a chassis.

A typical amateur application would be for use as a time base for a frequency counter. When measuring the frequency of a two meter transmitter, a temperature stability of about 30 Hz would be achieved. This compares with a stability of 300 to 700 Hz for most TXCO-type oscillators and 750 Hz to 3 kHz for uncompensated, high accuracy oscillators. *Janel Laboratories, 3312 S.E. Van Buren Blvd., Corvallis OR 97330.*

NEW SEMICONDUCTOR REFERENCE HANDBOOK

Just issued by Radio Shack, the nationwide electronics store chain, is a book every electronics experimenter or hobbyist will want. It's their new *Archer Semiconductor Reference Handbook*.

A cross-reference listing is included in the handbook for replacement of transistors, diodes, and other interchangeable devices. The total number of cross-referenced devices exceeds 36,000. These cross-reference/replacement listings are computer-selected and based on careful analysis of the important parameters of the listed devices.

The *Handbook* is a compilation of data on Radio Shack's line of Archer brand semiconductors. According to Radio Shack, every Archer device covered in this handbook is guaranteed prime – not "fallouts" or "seconds" – all are top quality, with known JEDEC, EIA, or manufacturer's numbers.

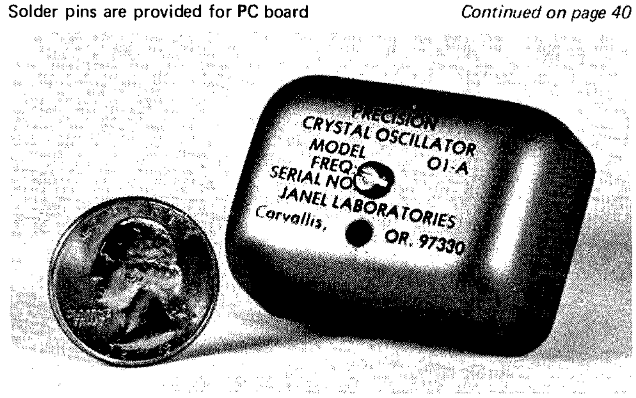
The handbook also has sections on the care and handling of transistors, soldering precautions, case styles and dimensions, and how to test transistors, as well as a glossary of words, symbols, and abbreviations.

The *Archer Semiconductor Reference Handbook* is available exclusively from Radio Shack stores and dealers. The 128 page handbook is priced at $1.95. *Radio Shack, a division of Tandy Corporation, Fort Worth TX 76107.*

PORTABLE DIGITAL MULTIMETER FEATURES 200 HOURS OPERATION

Data Tech announces a new low cost 3½ digit digital multimeter, with

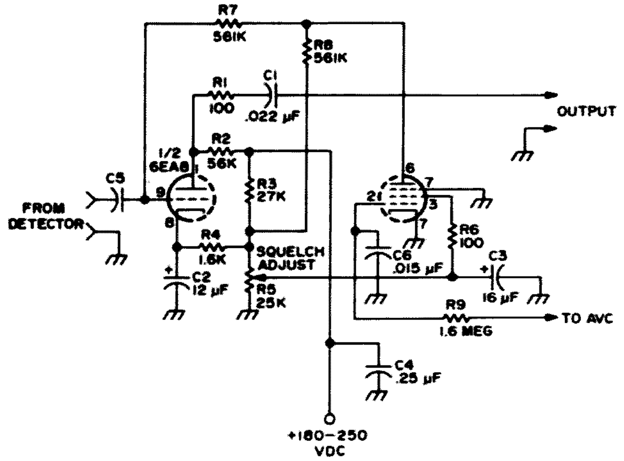
Continued on page 40



The Janel Laboratories precision crystal oscillator.

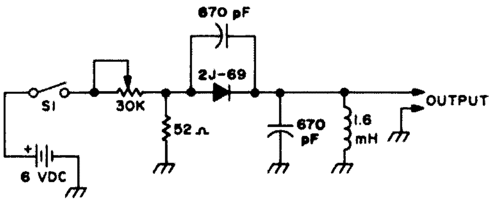
Q&A

This column will be a monthly feature of 73 Magazine. It is hoped that it will be of assistance to beginners and old-timers alike. We only ask that your questions be kept as general as possible. We will try to answer all queries received. Please mail your questions to Technical Editor, 73 Magazine, Peterborough NH 03458.



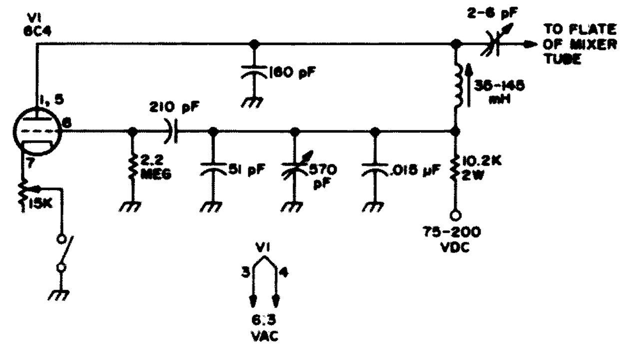
Q. Using one tube, how about a diagram for a squelch circuit?

A. See the figure. The only tube used in this circuit is a 6EA8. It must, however, be used with a set having avc. As shown in the diagram, this squelch is inserted between the second detector and the af volume control. For proper action, be sure there is good filtered dc. Use 1 W resistors throughout.



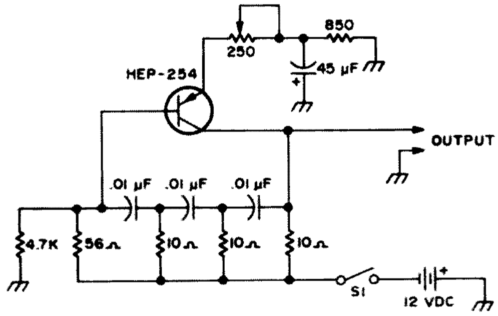
Q. Not using any crystals, and preferably a solid state device, recommend a 100 kHz sine wave oscillator which has a fair amount of stability.

A. This is a tunnel diode sine wave oscillator (see the figure) using a GE ZJ69 TD. When compared to a crystal oscillator, frequency was found to be stable as long as there were no drastic temperature changes. The sine wave output was nearly perfect. For long-term accuracy and stability, a crystal oscillator is recommended.



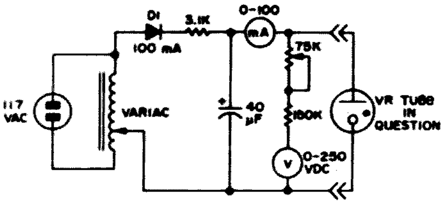
Q. Can a Q-multiplier be added to a receiver which uses an i-f of 1650 kHz?

A. Use the circuit shown. Mount the parts in a minibox for good shielding. Any voltage from 75 to 200 V will work fine. Although a 6C4 is used in the circuit, a nuvistor such as the 6CW4 also can be used. After installing, check the i-f alignment of the receiver.



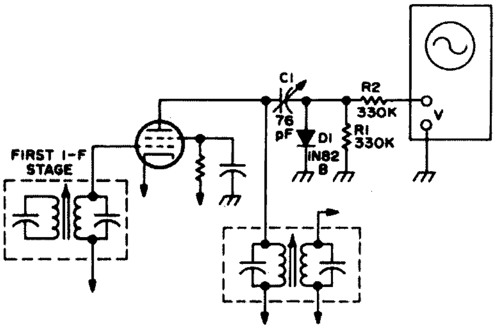
Q. Is there a way of designing an af oscillator so that it has an 800 Hz output?

A. Refer to the figure. The following transistors may be used in this oscillator: HEP-254, O.C.-2, SK-3004, AT30H. To increase the frequency, decrease the value of the capacitors in the ladder network.



Q. Is there a circuit for a simple VR tube checker?

A. The circuit in the figure works well. The variac voltage is varied up. When the VR tube fires, read the milliammeter and voltmeter. Good tubes will fire at their rated voltage and current.



Q. Is it possible to connect a scope to a receiver to see what incoming signals look like?

A. After installation of the signal takeoff and detector network (see the figure), the i-f stage may have to be realigned a bit.

Q. Is there an easy way to check the power output of a simple SSB exciter?

A. Yes – Connect the rf output of the SSB exciter to a dummy load (matching the output impedance). Across the load connect a vacuum tube voltmeter. Apply tone modulation to the exciter. Use the formula E2/R = P. Your answer will be average power, if you use an rms-calibrated VTVM. Make sure the VTVM is suitable for rf measurements.

Q. If, in nulling the carrier of an SSB transmitter, difficulty is experienced, what steps should be taken?

A. Disassemble the carrier null-trimmer capacitor and clean it with chloraphene. Remember, the carrier null should be set after the transmitter has thoroughly warmed up. For full carrier suppression, wait at least 20 minutes.

Q. Is it worthwhile to add a pot for vertical gain control to a scope with a step attenuator?

A. The circuit used for step attenuation is very effective and has a very wide range. Little will be gained by adding a pot. Furthermore, the vertical input is frequency compensated. The high input impedance of a good scope will be affected if a pot is added.

Q. Any idea as to what a sputtering noise within a small transmitter – when modulated – could be caused by?

A. With the room darkened, check for rf arcing in the final rf amplifier. Also look for arcing in the B-plus circuit due to close connections (sometimes due to vibration during transportation). Check for possible corrosion of various parts which could cause arcing.

Special Report

by Stan Miastkowski WA1UMV

REPEATER DEREGULATION — THE BOMBSHELL DROPS

It appears that the face and substance of amateur radio as we know it may be changing drastically in the near future. The key word is *deregulation*, a word that conjures up a wide variety of opinions. Is it good? Is it bad? Will it further amateur radio? Will it destroy it?

The process of deregulation has already started. It has come in small, bite-sized chunks. Novice class privileges were granted to Technicians, and instant upgrade has become a reality, as have code comprehension exams and the elimination of license fees. FCC field offices report that the number of new hams is climbing at an accelerating rate, portending great changes for our hobby.

Deregulation has come to the amateur community mainly because of one thing . . . Citizens Band. The explosive growth of CB has created a migraine headache for the licensing, enforcement, and rulemaking departments of the FCC. Their limited budget and limited staff means that the most effort must be focused in the area of most concern. That has become CB.

Amateurs can be justly proud of their record of self-enforcement. The FCC realizes that we have so far managed to mold ourselves into a service that can be left alone, for the most part. But can it last? With the increased numbers come increased problems. Repeater wars, malicious interference, bad language, and even violence have been cropping up lately. Where it will lead remains to be seen.

Deregulation can be a double-edged sword. Like the elementary school class that is forced to stay after school because of one person's misbehavior, amateurs must suffer and pay (literally) for the misbehavers on CB. Witness the two notices of proposed rulemaking before the FCC at the moment. The sale of linear amplifiers would be banned in the 24-35 MHz band under one. Under the other, type acceptance of all amateur equipment would be *required*. Although the linear amplifier ban can be lived with since licensed amateurs would still be allowed to home brew them, the type acceptance proposal hurts . . . right in the wallet. It's estimated that the price of an average transceiver would rise between \$150-\$300. It may be that amateur radio will become a rich man's hobby, like flying, horse racing, and yachting.

Despite the regression of type acceptance, deregulation is still the word within the FCC. The biggest bombshell is Docket 21033 . . . repeater deregulation. In brief, it would completely eliminate the present repeater licensing system and allow any licensed amateur to set up his own repeater on any amateur band.

The second bombshell is Docket 20777, which would change the emission-type limitations within a band to bandwidth limitations. This docket contains the seeds of both increased regulation and deregulation.

These notices of proposed rulemaking are two of the most important dockets ever out of the FCC that concern the amateur community. What does the average amateur think of them? Is he even aware of them? *73* has made an effort to find out. Hundreds of questionnaires were recently mailed to a cross-section of amateurs throughout the country. The poll included everyone from new Novices to old-timers, from professional radio engineers to clerks. The common denominator is the amateur license and the love of the hobby. The questionnaire polled amateurs on repeater deregulation, bandwidth proposals, and general operating habits.

This month, *73* concentrates on repeaters — both the current situation and where it is going. The results of the survey are contained elsewhere in this report. What seems clear is that there are as many different opinions as there are amateurs. Many hams who responded to our questionnaire took the time to remark at length about the state of things as they now stand. There seems to be a feeling running through the ranks that *something* has to be done to keep our hobby from being swallowed by the combined forces of unplanned deregulation and CB pressure.

THE CALIFORNIA SITUATION — AN EXAMPLE

The following is a letter from a Southern California repeater owner to a person who is alleged to have caused interference.

Dear Mr. :

I have called your home on three occasions and spoken to you twice (and your wife once) concerning the activity. The only result I have gotten so far is an immense telephone bill. Thus this letter. Since you came close to promising moderation last time we talked and the next day started transmitting a tone every time your telephone isn't off the hook in an apparent attempt to "clear the channel," and generally threaten people with violence and mayhem on the air (which is what I was asking you not to do), I can't wait to see what you come up with next.

I will certainly admit that there are people in the Valley who are trying to jam you off the air — included in that group is at least one guy who is a bootlegger and a guy who routinely stomps on established conversations through his own, as well as others' repeaters, and a guy who claims 146.94 as his exclusive channel. They are unreasonable, irrational imbeciles. Unfortunately, so are you. If anything can be proven by seeing who can *jam whom* off the air, it will probably be eventually settled by the FCC, the cops, or whoever can hire the biggest, meanest hit-men.

As a minimum, I insist that you not use your repeater to jam simplex conversations. If it is in fact true that your users cannot hear existing simplex conversations, installation of a lockout receiver and/or reducing transmit power or antenna height will be required. Jamming conversations is definitely illegal, and if you don't know that it's taking place, you are not properly functioning as a control operator.

Since your end of this conflict is a club, whose members pay money to use the repeater, it is in their best interest to take solution-oriented (as opposed to gum-beating) action. Being a club, it should be easy to take this up with the membership at a meeting or through your newsletter. It is somewhat harder to stop jammers in three counties, but if an honest attempt is made on your part to end this funny business, I and a number of other individuals will help you find and take legal action against the jammers — which you are apparently unwilling or unable to do.

I am not threatening to invoke the FCC. I doubt they will do anything — they seldom do, and I hope this can be solved without them, anyway. However, I am sending copies of this letter to several amateur radio magazines and the SCRA, in hopes that peer pressure will cause moderation on both sides, or that at least people laughing at you will slow you down. I regret that any of this is necessary.

COORDINATION: IS IT WORKING?

Despite an overwhelming response that frequency coordination is working, respondents to the *73* survey indicated that they believe that a national system of frequency coordination is needed. What is the state of frequency coordination? The latest issue of the *73 Repeater Atlas* shows nearly 3000 repeaters in operation throughout the country. According to our files, some of the more popular frequencies contain the following number of repeaters:

146.64 — 91
146.67 — 75
146.70 — 72
146.73 — 78
146.76 — 164
146.79 — 78
146.82 — 133
146.85 — 90
146.88 — 149
146.91 — 72
146.94 — 229
146.97 — 73

With numbers like those on one frequency, problems are bound to crop up — and have. See recent *73* "Briefs" for a running account of the Ohio RTTY war over the use of 146.70. *On the west coast, it* appears that behavior on many repeaters has regressed to the kindergarten level.

IS CALIFORNIA THE SHAPE OF THINGS TO COME?

James Rieger WA6EZL tells *73* that, "The problem here is that ham operators are at war with one another. Neither will vacate a channel which neither can use because of jamming, because they would then be the 'loser.' Additionally, the jamming signals, the threats, the playback of party tapes, and other pranks cover substantial areas of Southern California. The channels are rendered useless to operators.

"My hope is that peer pressure and publicity will cause both sides to take a more adult attitude toward the problem. It apparently will not solve itself. It's been going on for months and is increasing in nastiness. As an amateur operator, I am embarrassed and disturbed by these activities." For an example of the California problem, see the letter elsewhere in this report.

What is to be done? Whether repeater deregulation is approved or not, it appears that some type of national coordination system, or at least some sort of interaction of coordination activity, will have to be instituted. As part of the *73* poll, we asked frequency coordinators what criteria they use for geographical separation. Here are some of the answers:

"Strictly non-interference. The older machine has priority."
"HAAT, ERP, terrain, anticipated area of coverage."
"75 miles."
"Try to minimize overlap."
"100 miles."
"Common sense."

Those are just a few of the responses that we received. It becomes obvious that there is little consensus. In 1975, the ARRL proposed a system of national frequency coordination which never got off the ground, due primarily to the opposition of many of the large repeater coordination groups. The proposal would have used ARRL-designated area frequency coordinators, who would have had power to enforce coordination in conjunction with the FCC. One of the plan's requirements was that the coordinator be an ARRL member.

Whatever the pros and cons of national frequency coordination, amateurs must remember one thing: The FCC wants no part of it. The key word in Washington, especially with the new administration, is *deregulation*. The time, personnel, and paperwork involved is something the FCC wants no part of.

THE 73 SURVEY

73 sent out nearly 300 questionnaires, of which 236 were returned filled out. The breakdown of license classes is as follows:

32 Novice
34 Technician

THE ARRL BANDPLAN

Repeater Channels INPUT	OUTPUT	Direct Channels
146.01	146.61	146.40
146.04	146.64	146.43
146.07	146.67	146.46
146.10	146.70	146.49
146.13	146.73	146.52
146.16	146.76	146.55
146.19	146.79	146.58
146.22	146.82	147.42
146.25	146.85	147.45
146.28	146.88	147.48
146.31	146.91	147.51
146.34	146.94	147.54
146.37	146.97	147.57
146.40	147.00	147.60
146.43	147.03	147.63

147.90	147.30	
147.93	147.33	
147.96	147.36	
147.99	147.39	

97 General
51 Advanced
22 Extra

According to the survey, amateur radio operators spend an average of 8-10 hours a week on the air. Most also subscribe to two or more amateur radio magazines.

What do amateurs think of the FCC's repeater deregulation proposal? Here are the results from the *73* poll.

1. In general, do you agree with this proposal?
Yes 38%
No 61%
No opinion 1%

2. Do you feel that the existing licensing system for repeaters is working well?
Yes 72%
No 22%
No opinion 6%

3. Should the existing repeater licensing system be eliminated?
Yes 18%
No 77%
No opinion 5%

4. Should any licensed amateur be allowed to set up a repeater without the need for a special license?
Yes 24%
No 74%
No opinion 2%

5. Should repeater operation be allowed in all amateur bands?
Yes 19%
No 74%
No opinion 7%

6. Should crossband operation be allowed?
Yes 77%
No 22%
No opinion 1%

7. Should repeater logging requirements be eased?
Yes 77%
No 20%
No opinion 3%

8. Should repeaters be monitored at all times by control operators?
Yes 34%
No 62%
No opinion 4%

9. Should remote bases be allowed to operate on simplex frequencies?
Yes 70%
No 18%
No opinion 2%

10. Is frequency coordination working in your area?
Yes 80%
No 1%
Don't know 19%

11. Is frequency coordination working on a nationwide basis?
Yes 30%
No 1%
Don't know 69%

12. Is a nationwide system of frequency coordination needed?
Yes 69%
No 23%
No opinion 8%

13. If so, who should administer the system?
FCC 9%
ARRL 18%
National System of Frequency Coordinators 41%
No opinion 33%

14. Should nationwide frequencies be set aside for RTTY and simplex?
Yes 72%
No 20%
No opinion 8%

THE PROPOSAL
(Excerpts from Docket 21033, Released January 6, 1977)

"Petitioners request explicit recognition of so-called 'remotely controlled base stations.' They state that considerable confusion exists concerning the definition and operation of remotely-controlled base stations, and that there is a need for specific rules to regulate the operation of such stations. Petitioners have proposed specific rules which, if adopted, would both add to the rules several provisions concerning remotely-controlled base stations and substantially relax the requirements for the operation of such stations.

"The petitioner seeks simplification of the Amateur Radio Service logging requirements, particularly the rules requiring the notation of all third party traffic sent and received, the retention of station logs for one year, and the recording of transmissions from 'open access' automatically-controlled repeater stations. The petitioner states that much of the logging required by the Rules is of little benefit to either Amateur operators or the Commission and requests that logging requirements be relaxed ac-

A FEW THOUGHTS FROM W2NSD ON THE REPEATER SITUATION

What About Creeps?

Since the FCC does not give psychological tests when they give ham exams, we have our fair share of nerds — and some manage to get set up for two meters, more's the pity.

A little kerchunking of repeaters now and then is not a capital offense, but some characters carry this to a fault. This isn't as serious as the frustrated ham who gets mad at a repeater group who decides to get even via the garbage mouth route. We are all used to hearing only the cleanest of language on our repeaters, so when one of these guys starts with the dirty words, many of us are liable to overreact.

If you stop and think about it for a bit, you'll realize that, though the stuff may be objectionable, it really isn't going to hurt anyone. So don't make a great big deal out of it. You do want to do what you can to get rid of the idiot, and getting angry is your worst response . . . that's what delights him. He'll win a lot more attention that way.

Your best bet is to shut up and get busy with a direction finder on the input frequency (not the output — everyone knows where the repeater is). With a friend or two, you should be able to find the chap rather quickly. Then there is the question of how to get him to stop. If a phone call or a personal visit doesn't do the trick, you might think in terms of a personal visit by the entire club. A mob of fifty or so hams driving up and knocking on his door may get his attention.

Kerchunkers are harder to find. Their transmissions are usually a bit short for direction finding. There have been some successes with the use of a triggered scope. If you can get the chap on the input frequency and then measure the delay through the repeater, you can get a rough estimate of how far he is from the repeater. Another good trick is to use a fast triggered scope to see the leading edge of the kerchunker's signal. Oddly enough, every transceiver has a slightly different rise, and you can compare the kerchunker's pattern with those of other users later in the day. It is very unlikely that the kerchunker will never use the repeater normally. Eventually you'll spot him.

Open Repeaters, Closed Repeaters

As a traveler, you may run into the same thing I do. I get around a lot to hamfests, to see advertisers, etc. It is most discouraging to call in on the local repeater when you get to town and get no answer. I like to say hello, maybe find out a good place to eat, or a recommended place to stay. I announce myself on the repeater and hope for an answer. Nothing. I try again . . . "This is W2NSD portable 8 standing by; anyone around to say hello?" Nothing.

Okay, perhaps there is no one listening right now — that can happen. But then about 20 seconds later on comes W8—— calling WA8—— and standing by for him. WAS—— comes back and they talk. It takes a very short time to get the message . . . visitors unwelcome.

Other repeaters will put out the red carpet for you and make you happy you are a ham.

While I think we all appreciate that repeaters are not inexpensive to set up and maintain, on the other hand there is a nonprofit clause in the amateur regulations (no pecuniary interest) which must be kept in mind. Is it really legal for a repeater to use our non-commerical frequencies and force people to pay for the use of a specific frequency? I suspect not.

It would be a bit more expensive for closed repeaters to be set up on commercial channels, but it might be more honest. In the early days of repeaters, when there were far more channels available than were needed, perhaps we could afford the luxury of a small group settling down on a repeater pair and staking their claim . . . all others keep off. Today, when new repeater groups are unable to find a single available pair for a new repeater, I wonder if we can still afford the luxury of private channels.

If it were brought to the attention of the FCC in any formal way, I'm sure that closed repeaters would be outlawed. Our rules are very specific about all of our frequencies being open to all. Not even long-time nets have any "right" to a frequency. A repeater does not have a "right" to a channel. The FCC felt strongly enough about this to spell it out . . . if there is a station using the repeater output channel, the repeater control operator is not supposed to permit the repeater to be turned on and interfere with the chap on channel. Control operators do *not* observe this rule, but it is still the way things are as far as the FCC is concerned. Think about it.

LOOKING AHEAD

With the two meter band almost filled to capacity, and higher frequencies becoming increasingly crowded, the Southern California Repeater and Remote Base Association has planned ahead a bit. Here's a bandplan for 2300-2450 MHz.

Pair #	*Input*	*Output*
	2300.0 Lower Band Limit	
1.	2300.8	2350.8
2.	2301.6	2351.6
3.	2302.4	2352.4
4.	2303.0	2353.0
5.	2303.5	2353.5
6.	2304.0	2354.0
7.	2304.5	2354.5
8.	2305.0	2355.0
9.	2305.6	2355.6
10.	2306.4	2356.4
11.	2307.2	2357.2
12.	2308.0	2358.0
13.	2308.8	2358.8
14.	2309.6	2359.6
15.	2310.4	2360.4
16.	2311.2	2361.2
17.	2312.0	2362.0
18.	2312.8	2362.8
19.	2313.6	2363.6
20.	2314.4	2364.4
21.	2315.2	2365.2
22.	2316.0	2366.0
23.	2316.8	2366.8
24.	2317.6	2367.6
25.	2318.4	2368.4
26.	2319.2	2369.2
27.		2380.0
28.		2390.0
29.		2400.0
30.	2330.0	2410.0
31.	2340.0	2420.0
32.		2430.0
33.		2440.0
	2450.0 Upper Band Limit	

cordingly.

"We believe some of the proposals in the petitions we have received merit serious discussion, and we are herein proposing revision of Part 97 of the Rules which, if adopted, would result in a substantial simplification of the licensing and operation of stations in the Amateur Radio Service presently licensed as repeater stations, control stations, auxiliary link stations, and all other remotely-controlled stations, such as remotely-controlled base stations. The revisions we are considering would both accommodate many of the petitioners' wishes and be a significant step in the Commission's program of deregulation of the Amateur Radio Service.

"Since adopting rules governing the operation and licensing of associated stations in 1972, the Commission has steadily reduced the burden placed on applicants for and licensees of complex systems of amateur radio stations and has afforded such licensees increasingly greater flexibility in the operation of such stations.

"Our experience since adopting the rules regulating the licensing and operation of repeater and associated stations has demonstrated that amateur radio operators are fully capable of developing and operating complex systems of stations with a minimum of regulation by the Commission. We are aware of no compelling reason why amateurs wishing to operate repeater, auxiliary, control, or remotely-controlled stations should continue to be required to obtain Commission permission before beginning such operation, as they have in the past. For this reason, we propose to delete those provisions requiring that licensees obtain prior approval of the Commission to operate a remotely-controlled station and requiring that repeater stations, control stations, and auxiliary link stations be separately licensed. We would discontinue the issuance of station licenses with 'combined' station privileges: All amateur station licenses would convey authority to operate as repeater, control, auxiliary link, and remotely-controlled stations now operate.

"Similarly, we believe that operators of other remotely-controlled stations, such as remotely-controlled base stations, have demonstrated the capability of adequately controlling the emissions of such stations, and that the prohibition against the operation of such stations from control points in portable or mobile operation, presently contained in Section 97.110(b) of the Rules, may be unduly restrictive. Accordingly, we propose to revise the Rules to permit the portable and mobile operation of all primary, secondary, and club stations, when such stations are in auxiliary or repeater operation.

"Because no new station licenses would be issued to repeater stations, as such, we propose to discontinue our policy of assigning callsigns prefixed with the letters 'WR'. Stations presently assigned such callsigns would be permitted to retain them indefinitely. A licensee wishing to engage in repeater operation and wishing to obtain a 'WR' callsign would be required to request that prefix.

"Because stations in repeater or auxiliary operations would be taking advantage of specialized modes of operation, we believe the transmissions of such stations should be distinctly identified. We propose to require that auxiliary or repeater operations conducted by stations with 'traditional' callsigns be identified by the addition of a distinctive suffix to the station callsign. Stations in repeater operation would be identified by the addition of the suffix 'R', 'RPT', or the word 'repeater' to the regular callsign.

"A petitioner seeks relaxation of certain logging requirements, and we are considering deletion of the requirement that communications from open access stations in repeater operation under automatic control be either monitored in real time by the duty or control operator or recorded and the recording retained for a period of thirty days. This requirement, which was originally intended to ensure that licensees have the capability of determining whether their stations were being used properly during periods when no control operator was on duty, has proven to be of little benefit to the Commission and may unduly burden licensees operating 'open' repeater stations under automatic control. Of course, the licensee of the station would continue to be responsible for its proper operation.

"Additionally, it appears that many Amateur operators seek greater flexibility in the choice of frequencies for repeater and auxiliary operation. We are proposing to permit both repeater and auxiliary operation on all frequencies allocated to the Amateur Radio Service, except 435 to 438 MHz, and to delete the requirement that frequencies below 225 MHz used for auxiliary operation be monitored by the control operator before and during periods of operation. We would revise section 97.63 of the Rules, however, to emphasize the two principles which have made possible the efficient operation of many amateur radio stations in relatively small spectrum space, namely, that a station using a frequency has first priority in such use over other stations, and that all frequencies allocated to the Amateur Service are shared on a non-exclusive basis. It is presently the responsibility of amateur licensees to strike an appropriate balance between these principles to ensure fair and efficient use of the available spectrum.

"The Commission is aware that adoption of the rules proposed herein could result in a significant increase in the number of repeater, remotely-controlled stations, and associated activities pursued by amateur licensees. We are also aware that severe frequency congestion is present in some parts of the country, and that the possibility exists that increased interference might result from adoption of these revisions. Many amateurs have voluntarily established techniques for managing the available spectrum, and we commend such efforts. We are not prepared to make specific recommendations in this area at the present time."

THE LIGHTER SIDE OF REPEATER COORDINATION, FROM THE CHICAGO FM CLUB

Have you ever felt that you should have more power over others in amateur radio. Your ego need a boost? Tired of having sand kicked in your face by other people on the band whose only claim to fame is that they are better operators than you? Make something of yourself the easy "Repeater Council" way!

Just follow these easy steps, and many will think of you as God, just as you do:

1. Create a file of all legitimate articles that claim that repeater coordination is necessary. These can be rewritten and distorted later to support your dynasty when under fire.
2. Coordinate a few repeaters, preferably only those using surplus commercial gear or new commercial repeaters. Ignore the "amateur" amateur repeaters until they come crawling to you on their knees. You are building the base for your power structure.
3. When one of the "amateur" amateur repeater groups (henceforth referred to as "basement repeaters") complains of interference caused by a "coordinated repeater," offer to let them move to another frequency. If they decline, label them as a "pirate repeater," and do your best to destroy their credibility.
4. Attempt to be recognized by some national organization as the sole frequency coordinating authority. This is your big step towards credibility.
5. Be careful not to support experimentation, public service groups, or anything except for narrow band FM repeaters on two meters, 220 MHz, or 432 MHz. Ignore at all costs innovations like crossbanding, ATV repeaters, portable repeaters, SSB repeaters on 10 meters, etc. Steadfastly refuse to recognize simplex as a legitimate, useful mode, and refer to it as if it were merely a squatter on the "repeater band." (An alternative is to form a simplex council to coordinate simplex users.)
6. Above all, refuse to coordinate any repeater group who refuses to pay dues "... to support the council ..." This is easily accomplished by labeling any unpaid repeater groups as pirates and assigning the same frequency pair to another machine in the same area. If a group is not current in dues, even after being coordinated by you, refuse to send them any notices of actions by the council. If the bank account becomes suspiciously large and membership services are nonexistent, open another secret account at another bank.
7. Never allow the membership to vote on anything. Make all decisions in private, and advise the membership that an "executive decision" has been made. If something *must* be put to a vote, put it in final form before asking for comments, and ask for an approval of the "principles" involved, promising a new draft. Never record the promise of a new draft, and treat the first draft as the approved version.
8. If all else fails to maintain your absolute authority over the band, and if too many nonmember repeaters are going up, or coordinated repeaters stop paying you their dues, make a proposal to the FCC to make coordination (and therefore dues) mandatory for all repeaters. This is where the articles on the importance of frequency coordination can be distorted and used to advantage. If this docket is passed, you have established a real dynasty! You can stifle all experimentation and abuse your authority! You've made it to the top of the heap and created a "machine" which will feed your ego (and your pocketbook) for the rest of your life! Congratulations!

Review

THE RSGB VHF-UHF MANUAL
by D. Evans G3RPE and
G. Jessop G6JP,
Published by
Radio Society of
Great Britain, $12.95

The job of keeping manuals even somewhat abreast of the rapidly changing state of electronic communication art must be a frustrating one. It's even worse when the manual's subject is VHF and UHF, the frequencies where techniques have undergone the most rapid change.

In an effort to bring these changes to the radio amateur in handbook form, the Radio Society of Great Britain has brought out the third edition of its *VHF-UHF Manual*. Because UHF-VHF propagation is accomplished by a different mode than that for the high frequencies, the handbook's first chapter is devoted to an explanation of how these higher frequencies are radiated. Each of the several modes of propagation is discussed in great detail, and numerous charts are used to simplify and clarify understanding.

Tuned circuits peculiar to the high frequencies are described next. The transition from lumped constant to linear to cavity is shown. Then the selection of the optimum circuit for a stipulated application is aided by a comparison table. Coupling techniques for VHF-UHF are illustrated in profusion. The variety of transmission lines covered in the handbook may astonish some readers; each is presented in adequate detail. The helical resonator and microstrip lines are shown. In addition to the more conventional tuning methods, the use of varicaps is discussed. A logical transition from tuned circuits to receivers follows.

In the next chapter, noise factors are discussed, pointing out the many sources of noise in a receiver. This, of course, includes both vacuum tubes and solid state devices. Many (tube and transistor) circuits are shown for amplifiers, mixers, and oscillators (crystal-controlled and variable frequency). Unusual devices such as parametric amplifiers and hot carrier mixers are explained. Types of demodulators for FM, PM, AM, and SSB are shown in profusion. (One can never complain of not having every type presented!) Specialized circuits (squelch, etc.) associated with each demodulating method are given ample space. As is the custom in British publications, building instructions are given for many components (and even for a complete 2.3 MHz receiver). And these, still following British custom, are presented in minute detail.

As is to be expected, a chapter on transmitters follows receivers. In it, there is a considerable degree of repetition of information presented under "Receivers." Perhaps this is good, because it saves having to search under several headings to find the whole story. But there is new info, too, including excellent tables to help you select tube types, circuits for tuned stages, and even the length of leads that can be tolerated on fixed capacitors. The section on transistor power amplifiers is outstanding. So is the one on modulation theory. It even dares to explain "capture effect" in FM reception, a subject other handbooks avoid like the plague! Speech processors are touched on lightly, omitting any reference to truly modern methods. SSB, its principles, its several methods of generation, its amplifiers, and its transverters are accorded ample treatment. Much space is devoted to construction information. (As with the receiver section, these instructions are given in great detail.)

There's a short but good chapter on filters (bandpass, trap, etc.). Antennas rate a long chapter that starts out with the concept of an isotropic radiator and then progresses through power gain, bandwidth, aperture, and polarization. Each aspect is covered well. Next come feeders, their design and construction, and their matching to loads (antennas). Finally come antennas in all their multitudinous configurations. You'll find plenty of hard-to-get information, the type that never seems to be at hand when you're searching for it. There are tables for losses due to skin effect, or losses from the resistance of different metals used in elements, and information on electrolytic corrosion, arranged in an anodic/cathodic progression.

Microwaves, with their peculiar form of generator-to-antenna transmission (waveguides), rate a full chapter. Concerning waveguides, one finds out about the mode of propagation within the guide, how to get around a corner, how to tune a waveguide, how to devise a directional coupler, how to fabricate chokes. Next, one comes upon isolators and circulators. Perhaps more could have been said about these circuit configurations. Klystrons and Gunn oscillators (typical examples of vacuum tube and solid state SHF signal generators) are given a few pages. Then one gets to equipment — sixty pages of building instructions! Since there are only two practical ways of acquiring microwave equipment, "liberating" it from military or commercial sources or building it yourself, such a plentitude of construction details is indeed valuable.

The geometry of orbiting satellites starts out the chapter on space communications. This established, there's an explanation of free space path loss, and then a discussion of just what equipment an amateur would have to have in order to make contacts by way of a satellite. Moonbounce communication rates several pages.

The final chapter is on test equipment. Not all of this is unique to VHF-UHF, but the higher frequencies are favored. The measurement of rf power decidedly is slanted toward techniques peculiar to UHF. (I can't say that for the rf bridge described, though!) The several types of VHF-UHF dip oscillators are well-designed and building instructions are good. PIN diodes as attenuators, diodes as white noise generators, and FETs as crystal-controlled signal generators follow usual patterns. A very short mention is given to power splitters and combiners. A data section and an index conclude this book.

As with most publications, no matter how painstakingly proofread, goofs creep in. Small things, mostly, like errors in circuit drafting. These are easily spotted and should cause a careful reader little confusion.

The contributors and the editor of the *RSGB VHF-UHF Manual* have done a commendable job. It's factual. It's even interesting! And that's a large job for any technical book. I highly recommend it to any radio amateur who's truly interested in VHF-UHF. Interested, that is, beyond just playing with black boxes. Interested in expanding his comprehension of all of the many facets of communication in our higher frequency bands. *Radio Society of Great Britain, 35 Doughty St., London WC1N 2AE.*

THE BIG BROTHER GAME
by Scott R. French
Lyle Stuart, Inc. $7.95

Technology always filters down to the masses, someone once said, and he was right. Just last month, a Princeton University senior unveiled his design for a $2,000 atomic bomb (less plutonium) powerful enough to waste half of Manhattan yet small enough to fit inside a U-Haul trailer. Off-the-shelf texts contained sufficient data for bomb building.

While *The Big Brother Game* won't show you how to be the first on your block to blow up the world, it takes the wraps off well-kept secrets of government, big business, private investigators, and security agencies — how to bug a room, pick a lock, tail a car, play the credit game, change an identity, build a pistol silencer, be a spy. And as author Scott French implores, "If someone is doing it to you, stop it or do it back." He shows how to debug a room, evade followers, tell if your phone is tapped, keep premises secure, keep government out of your business, and obtain your government dossiers.

According to French, the FBI's Identification Division has files on over 190 million Americans. This includes anyone who has been in the armed services or arrested. Agencies other than the FBI keep citizen files, such as Welfare Departments, Public Schools, CIA, FCC, Veteran's Administration, and one of our favorites, the IRS.

Since the passage of the Freedom of Information Act in 1975, these agencies and others must allow citizens access to their personal files. French outlines steps to retrieve them.

While French sometimes skirts the legal edge, he rarely steps over it. After all, if it's okay for the FBI, it's okay for us; right? So, "Buy where the pros buy," French cajoles us. He lists names and addresses of manufacturers and dealers of polygraphs, bugging and debugging devices, shoe heel transmitters, lock-picking tools (used by police everywhere), and more.

And for the do-it-yourselfer, this volume contains 25 pages of James Bondian circuits, from wireless microphones to laser surveillance devices.

The Big Brother Book keeps a lively pace with tantalizing tidbits of private eye lore and nifty fun-to-tell facts — you can declare bankruptcy every 6 years and wipe out all your debts. The French police supposedly use a 25-35 kHz high-powered sound generator for crowd control. A chemical product sold under the name WD-40 spreads a light oily coating on objects which won't support fingerprints. Be the life of the party with these.

It's not the type of book you want to read straight through though. Rather, dip into it from time to time and slowly dribble information into your brain.

But for all this seemingly underground information, French warns us not to judge his motives for telling it all.

"You see," he says, "this information exists . . . Many already have this information and some are using it within the for-the-people, by-the-people law bit, some are not . . . Now by god, we all have it. Should you choose to go into the industrial spy business, start snooping around on your spouse, use this information for personal gain, use it to prevent others from abusing your rights, or simply just read it for the love of curiosity's sake, the responsibility is yours."

So it goes. Mr. French keeps the technology filtering down, and the rest is up to us.

THE RADIO AMATEUR'S LICENSE MANUAL
Published by the
American Radio
Relay League,
Newington CT, $1.50

The latest ARRL license manual, the 75th edition, has quite a lot of information for the money. It gives questions for study of the five classes of licenses, as well as general information on amateur licensing, international regulations, US regulations, a chart of the frequency subbands, US radio districts, and examination schedules for all the FCC examination points.

A great deal of the information in certain sections is obsolete, due to changes in the FCC regulations, but the corrections are in the back of the book, which you should read first. There are four pages which bring the information substantially up to date.

There are no more fees, for the moment, and the Novice power limit has been raised from 75 to 250 Watts. These two points are not covered. Changes in the logging rules are not as clearly explained as I'd like. The new rules eliminate all logging except the date the station is first put into service

and the date it is taken out of service, unless you have handled third party traffic or have permitted another licensed amateur to control your station. Third party traffic, of course, includes letting anyone, even a member of your family present in the shack, talk on the station transmitter.

Probably the most important change, which is not mentioned, is the fact that Technicians have been given credit for having taken their test before an FCC examiner, and are entitled to become a General licensee by merely passing a 13 word per minute code test. The Technician test was the same in coverage as the General license and thus the amateur has been able to become a General without appearing before the FCC for a written exam. (Of course he must still appear for the code test.) This should inspire a lot of Technicians to become Generals.

The manual does not make specific answers available for memorizing, but gives enough coverage of each answer so that by study you can cope, we hope, with any variation of the question. Often, when an answer is memorized, a slight change in the wording of the question makes the memorized answer completely wrong.

If I were just starting in radio, looking ahead to the material for higher classes of license beyond the Novice would probably scare me a little. If I lacked motivation, I might give up the whole idea. I believe I would rather start with a study guide for a Novice only, and cross the next bridge when I came to it.

The other thing is the fact that with all the changes in the rules evident in the manual, requiring changes in the book, I would wonder if the rest of the book would be useful to me when I was ready to step up to another license. I think I would rather have a current book.

MAINTENANCE SERVICE MANUAL, FT-101 SERIES
Published by Yaesu Electronics Corp., $25.00

Yaesu has been importing FT-101 transceivers now for over six years, and it's pretty hard to find anybody who doesn't respect their quality and portability. Over those years, Yaesu has steadily improved the 101, incorporating receiver improvements and increased frequency coverage. Three basic versions of the 101 have been produced, ranging from the original FT-101 to the FT-101-B, and the current FT-101-E/EE/EX series. Hundreds of thousands of these radios are in use around the world, along with Yaesu's line of accessories.

Now Yaesu has gone a step further than the normal operating manual provided with the 101 series transceivers — they've produced a maintenance service manual that every 101 owner ought to have. To quote Yaesu General Manager Bernie Tower's (W6RNW) introduction, "We have departed from the traditional 'military format' in writing technique and the style may seem too informal on first reading; however, remember that our goal was to make this manual easy to use." The contents are excellent, with an orderly flow through installation, tune-up, theory of operation, and parts identification in the opening section, plus step-by-step coverage of accessory interface and disassembly of the unit in section 2. In all, there are nine segments to the manual, including thirty pages of factory-recommended modifications. (That will probably be the most sought after portion of the manual.) In addition to the hundreds of schematics and x-ray views of the PC boards contained in the first eight sections of the book, Yaesu also included 9 foldout schematic diagrams covering all three versions of the FT-101. To conclude, we turn again to Bernie Tower's introduction. "You will find inside these covers not just a list of clipped out circuit descriptions and redrawn prints, but also all the tricks and neat stuff that the factory has developed — extras that never show up in operators' manuals, such as part location data, test points, a wealth of 'How To Do It' instructions, and the special information our service files contained." That says it in a nutshell!

RADIO COMMUNICATION HANDBOOK (Vol. 1)
Published by Radio Society of Great Britain, $18.95

One weakness of handbooks is the inability of publishing one that is abreast of the state of the electronic art. This weakness is compounded when revisions are made attendant to bringing out later editions. There's just too much temptation to carry over material from the previous printing, sometimes in its entirety, sometimes with minor updating.

The fifth edition of *Radio Communication Handbook*, edited by Pat Hawker G3VA, shows that a determined effort was made to avoid such a pitfall. The effort was partially successful.

Volume 1 of the new edition shows promise of being a noteworthy advance in handbook publication. Much obsolete material has been eliminated, with old subjects treated in a new way and new techniques introduced.

Why should American radio amateurs go to a British handbook when there are several excellent ones published in this country? In partial answer, it may be said that the British pay more attention to details of theory, and much more attention to precise construction information. Another part of the answer may lie in the manner in which the British authors approach the explanation of principles. It's somewhat different, and there's no doubt that better comprehension of a subject can come from a study of a variety of presentation styles. It's good to bear in mind that this handbook does not replace any of the domestic ones. It serves to complement, not to supplant.

As is the case with other handbooks, this one starts with principles. But, unlike the others, it doesn't mention theory until it has introduced components, giving types and applications. Then it brings on the theory of how these components act in circuits. Although the theory is simple, the handbook does not presume the reader is "simple." The presumption is that the reader is intelligent and not frightened by the sight of a few mathematical equations. It's significant to note that the examples involve modern components and applications, a pleasant contrast to most handbooks (which have not changed from presentations that were old in the 1920s!). The *Radio Communication Handbook* is not totally devoid of faults, however, as it bows to the antiquated custom of having current flow opposite to electron flow!

The chapter on principles is extensive enough to cover not only the simple basics, but also to go far beyond to tuned circuits, filters, rf impedance matching, radiation and propagation, amplification, feedback, modulation in its many diverse forms, and its inverse: detection. It's thought-provoking to note that the British author declares the crystal detector to be the first-used type, undoubtedly causing his compatriots, Marconi (magnetic detector) and Fleming (thermonic diode), to flip in their graves!

Another chapter explains vacuum tubes. It is more or less conventional, except for the profundity of its detail and the space devoted to unusual tube types and applications. Modern design has drifted far away from the mundane applications of tubes, leaving only those instances in which the tube uniquely serves a purpose. And it's for these unique purposes that the text is admirably suited.

Only five pages are used to expound on the theory of semiconductors. Then the book gets into specific types, their behavior, and their applications. The author does it so well he can be forgiven for writing "cat's whisker" instead of "cat whisker." He's not the only one to make that mistake! He is to be congratulated on covering the IMPATT diode, the PIN diode, and the Gunn diode so effectively. Transistors of all commonly-used types are shown, and their uses discussed. ICs get short shift, with a promise to mention them later (in connection with their application in equipment).

Chapter 4, Receivers, starts by defining terms and talking about what would constitute a really good receiver. Then it describes the many generic types of receivers. This is done not so much in detail as in scope — the reader will have an acquaintance with just about every type of receiver used. Terms such as sensitivity, selectivity, stability, spurious responses, cross-modulation, blocking, intermodulation, and tuning rate are defined and expounded upon. Then design factors are discussed, with a wide range of choices. Circuits galore are shown. For the very ambitious, construction details are given. In this, one sees a marked difference between American and British handbooks. The British present much greater detail. Too, they expect the reader to construct more mechanical components. If you're a dedicated do-it-yourselfer, you'll appreciate such instruction!

A separate chapter is devoted to VHF and UHF receivers. As might be expected, it opens with the differences between designs and components for the higher frequencies, and those for the HF region. Next, it presents circuits — oscillators, buffers, multipliers, amplifiers, and mixers. The circuits are followed by construction details (with detail underlined) for a variety of receivers, converters, oscillators, preamplifiers, and power supplies. You'll even see such unusual items as a folded hybrid ring mixer using linear (not lumped constants) elements.

Chapter 6 is on HF transmitters. It follows the usual outline, with just a bit (in this writer's opinion) too much space on crystal oscillators. Oh, it's good. But maybe too good for the strictly limited use of crystal oscillators in modern transmitters. It's equally good on VFO design, discussing the effects of external factors (temperature, following stages, etc.) on short-term stability. There's an astonishing variety of VFO circuits, with component specifications. Both tube and solid state types are shown.

From oscillators, a logical sequence is followed to coupling circuits, and then on to buffers and amplifiers, with a sidestep to frequency multipliers. Power amplifiers, as might be expected, get the big play. A bit too much space is allotted to neutralized triodes. (When was the last time you built one?) The design of tank circuits is given much (and merited) detail. Output circuits for both tube and transistor active elements are also discussed. Construction information is given for several transmitters.

Then, and only then (for some illogical reason), there's a discussion of the principles and merits of SSB. Then comes the usual plethora of circuits for generating DSB signals or SSB signals. Mixers are covered well, as are the considerations for mixing frequencies. The usual advice is given on the selection of a suitable active device (tube or transistor) for an amplifier, with due thought given to the various conditions that lead to linearity of operation. The use of two-tone af inputs to check PEP output is discussed in detail. Omitted, however, is any reference to the use of a spectrum analyzer as the ultimate device for ascertaining overall signal purity. A considerable space is given to construction of SSB transmitters. Both tube and solid state types are shown. In each instance, highly detailed information is provided.

The seventh chapter is devoted to VHF and UHF transmitters. It repeats quite a bit of information on crystal-controlled and variable oscillators. Linear circuits, both transmission line and cavity types, are explained very well, but there is some repetition of the modulation, mixing, and oscillator frequency selection data provided in previous chapters. Construction details are provided for several UHF transmitters, and they are probably

superior to any available in other handbooks.

A short chapter is devoted to keying and break-in systems. Some are simple, others complex. You can take your pick from a variety of types.

Considering current times, the *Radio Communication Handbook* devotes too many pages to the many methods of producing amplitude modulation (AM). It's improbable that a half dozen AM transmitters have been built in the USA or Canada in the past five years, and I doubt whether the system is any more popular among English builders! So why such detail? On the positive side, considerable space is given to frequency and phase modulation. Speech amplifiers are touched upon, as are speech processors, the latter in a rather uninspiring manner. The chapter is concluded with methods of measuring modulation quality.

The final chapter of Volume 1 is on radioteleprinters. It's short but adequate. In this instance, little construction advice is given. Textual material is followed by an excellent index. American readers may not care for the British practice of omitting page numbers in favor of chapter subdivisions. It's easy to live with, though.

In summary, Volume 1 of the fifth edition of *Radio Communication Handbook* fills a niche in radio literature that has been somewhat neglected With a few exceptions, it's thoroughly modern, devoted to current techniques and components. It belongs on the bookshelf of every serious amateur of radio technology. But it should be set away on that bookshelf only after it has been well-thumbed! *Radio Society of Great Britain, 35 Doughty St., London WC1N 2AE.*

FCC

Report No. 12746
ACTION IN DOCKET CASE
FCC PROPOSES TO SIMPLIFY AMATEUR LICENSING AND CALLSIGN ASSIGNMENT
(DOCKET 21135)

On March 3, the Commission proposed to simplify the licensing and callsign assignment systems in the Amateur Radio Service.

The FCC said that the explosion in interest in personal radio communications had placed a heavy burden on those Commission staff issuing licenses. The Commission noted that it was aware that many Amateur licensees were dissatisfied with the speed of license processing and indicated it was considering methods to improve the process.

It added that its resources for processing amateur applications were extremely limited, and that its lack of resources now precluded all but the most basic licensing functions.

Accordingly, the Commission proposed to simplify Amateur licensing by discontinuing the issuance of all amateur licenses, other than primary station licenses, including military recreation, club, special event, Radio Amateur Civil Emergency Service (RACES), and secondary station licenses. (The Commission noted that in Docket 21033 it had proposed elimination of repeater, auxiliary link, and control stations.)

Licensees currently holding such station licenses would be permitted to retain them, but would not be able to renew them upon their expiration. In proposing elimination of all but primary station licenses, the FCC said that a disproportionate percentage of its resources were devoted to processing applications for non-primary amateur stations, which constitute only a small part of the amateur population, and that such resources must be allocated in a more efficient manner.

The Commission also recognized that elimination of the station types involved would have an impact on some individuals, but that it believed any such impact would be minor.

The FCC noted that the assignment of amateur callsigns also occupied an inordinate amount of staff time, and proposed to simplify the callsign assignment system in the Amateur Service by prohibiting entirely the assignment of specific callsigns and callsigns based on particular formats. All callsigns would be assigned on a systematic basis by the Commission under the terms of the proposal. Licensees holding Amateur Extra Class operator licenses would be permitted to obtain nonspecific 1x2 and 2x2 callsigns, however.

Comments on the Commission's proposals, which would amend Parts 1 and 97 of the Commission's Rules, are due by June 2, and reply comments by June 30.

Report No. 12743
ACTION IN DOCKET CASE
FCC SETS "CLOSED SEASON" ON 2 TYPES OF AMATEUR RADIO APPLICATIONS
(DOCKET 21135)

The FCC has announced that, effective March 3, there will be a "closed season" on filing applications for special event stations and secondary stations in the Amateur Radio Service. (A secondary station is a separate station licensed to an amateur operator for a location other than the primary station site, such as a vacation home or office. A special event station is one licensed for temporary use involving an event of either general interest to the public or of particular interest to amateur operators, and intended to draw favorable public attention to the Amateur Service.)

The Commission said that it had been receiving many frivolous applications for secondary station licenses during the past two months, and that these applications were beginning to burden its amateur radio processing staff. The Commission also said that it anticipated a flood of new applications for secondary and special event station licenses as soon as its proposals in Docket 21135, one of which is to eliminate the availability of such station licenses, are made public.

To make possible the continued efficient processing of other amateur radio license, the Commission imposed an immediate closed season on the filing of applications for special event and new secondary station licenses. All applications for special event station licenses or new secondary station licenses received on or after March 3 will be returned, the FCC said. Applications for renewal or modification of existing secondary station licenses will continue to be accepted.

AMSAT

Mode B users of the AMSAT-OSCAR 7 satellite were treated to an unexpected bonus of over three continuous weeks of orbits in which the 70 cm to 2m mode was kept on. This was done to reduce a battery overheating problem which had developed. In mid-December, 1976, the nicad battery temperature was about 36°C (79°F). As the weeks passed, the temperature began to increase because the orbit of A-O-7 was such that the satellite saw less and less of the earth's shadow. By January 17, 1977, the bird was in complete sunlight, and the temperature continued to rise at an alarming rate to over 44°C (111°F). This overheating was being caused by the constant charging of the battery, especially while in Mode A when the load is relatively light. Switching to the redundant charge regulator had little effect on the rising temperature, so the decision was made to command A-O-7's 70 cm to 2m on continuously, in order to reduce the charging of the battery.

With a number of stations still running excessively more than the recommended maximum 100 Watts ERP, there would have been more occasions of A-O-7 switching to Mode A or even worse to Mode D, the recharge mode. This switching of modes occurs when excessive current demands cause the bus voltage to drop below a preset level. When this occurs, the sensor's undervoltage signal causes the mode switch, which is supposed to protect the satellite's battery from being further run down. Even though the battery was being charged to a normal value, it was not able to supply the very heavy peak currents being demanded when high-powered satellite users were transmitting, so it switched modes.

In order to reduce the number of mode switches which had been occurring in December and January, we tried to keep A-O-7 in Mode C, which is a lower power 70 cm to 2m mode. When in Mode C, there were no more false mode switches, so the primary telecommand station for A-O-7, VE3SAT, commanded the satellite into this mode whenever possible. Because of its design, the satellite switches from Mode C to B after 24 hours have elapsed on the spacecraft's clock, and from Mode B to A after another 24 hours. When a false mode jump occurs, the clock is reset. This lets us know when the jump occurs, so we can see where the satellite was when this happened.

As you can imagine, commanding became very complicated when the mode jumping began to occur, but Randy's 8080 microprocessor-based command station came through with an excellent performance, keeping A-O-7 in the correct mode during the battery temperature crisis. By mid-February, the battery temperature began to stabilize, and then to decrease enough to allow A-O-7 to switch back to its normal schedule of Mode A on odd days of the year and Mode B on even days. This switch occurred on February 18, 1977.

One final note of interest concerning the VE3SAT automated command station: During the last week of the battery temperature problem, Randy was called away from home, leaving the automatic system on to run on the information programmed into its memory. Among the duties which it performed flawlessly were keeping the satellite in the proper mode, automatically commanding the 2m beacon from the codestore mode to the proper telemetry mode for an acquisition by WØLER of sun angle data, automatically loading the on-board A-O-7 codestore memory with a new message, switching the beacon from RTTY teletype telemetry to the codestore run (which played back the new message to the world for a day), again switching the beacon to the telemetry mode, and programming the satellite to switch to Mode A on February 18th.

A-O-6 NICAD CELL FAILS; SUNDAY DESCENDING NODE ORBITS DISCONTINUED

A failure of part of the 18-cell A-O-6 battery has forced the early curtailment of the Sunday descending node (north to south) orbits of the satellite. The failure of the cell was noticed by a number of telemetry gatherers who saw an abrupt drop in the channel 3A telemetry count, from counts around 62 to counts around 48. This indicated a problem in the upper half of the battery series string, since the half battery voltage measurement was normal (the lower half, that is). Since the battery is a series of cells, the failure of a single one has an adverse effect on the bus voltage. The bad cell acts somewhat like a diode when the battery is discharging, and like a series resistance when it's charging. The effect thus is lower available battery voltage and a reduced charging current. Combine the cell loss with the already reduced Ampere-hour capability of its 4-year-old battery, and the result is that the operating schedule of A-O-6 must be reduced.

The Sunday descending node orbits, which were scheduled to be available until the end of March, 1977, had to be discontinued. Also, the worldwide network of A-O-6 command stations has been instructed to turn off the satellite before it goes out of range during scheduled on orbits. The present schedule for A-O-6 calls for the transponder to be on for normal use on ascending node (south to north) orbits on Mondays, Thursdays, and Saturdays, UTC. This schedule will remain in effect as long as the battery remains stable at present levels. In the event of further degradation of the battery, it will become necessary to further cut back on the present schedule of the transponder.

CONTESTS

Editor:
Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

My apologies to WA4BMC for incorrectly listing her address in the January issue as being in Lake Worth FL. The correct address is: PO Box 6811, Southboro Stn., *West Palm Beach* FL 33405. A large SASE with return postage for 3 oz. will bring complete information on county hunting and the MARAC organization, as well as mobile reply QSL cards, QSL bureaus, etc. Hope this did not inconvenience anyone.

TRIPLE LETTER QSO PARTY

Starts: 2000 GMT May 7
Ends: 2000 GMT May 8

All amateurs are eligible and invited to participate. Use all HF bands, 160 to 10 meters. One contact per band per mode (CW and phone only) with each station.

SCORING:

One point for each letter repeated in the suffix of the call of the station contacted. Example: WB2GFE = 1 pt.; WØETT = 2 pts.; WØEEE = 3 pts. Two letter calls get one extra point. Multiplier is the total number of states, Canadian provinces, DX countries (other than US and VE), and number of 3-letter calls. Total score = QSO points times multiplier from each band.

EXCHANGE:

Serial QSO number and RS(T).

ENTRIES:

Send logs postmarked no later than June 1st to WØEEE, UMR Radio Club, Eng. Bldg., Univ of Mo., Rolla Rolla MO 65401. Mark the envelope: "ATTN: QSO PARTY."

GEORGIA QSO PARTY

Starts: 2000 GMT,
Saturday, May 7
Ends: 0200 GMT,
Monday, May 9

Sponsored by the Columbus ARC, there are no time or power restrictions, and contacts may be made once on phone and once on CW on each band. Oscar counts as one band. GA mobile or portable stations count as a separate station in each county.

EXCHANGE:

QSO number, RS(T), and QTH – county for GA; state, province, or country for others. GA to GA contacts are permitted.

SCORING:

Each completed contact counts 2 points. GA stations multiply QSO points by number of different states and VE provinces worked. DX stations may be worked for QSO points, but do not count as multipliers. Others multiply QSO points by number of GA counties (159 max.). No repeater QSOs permitted, except via Oscar!

FREQUENCIES:

CW – 1805, 3590, 7060, 14060, 21060, 28050; SSB – 3900, 3975, 7245, 14290, 21360, 28600; Novices – 3718, 7125, 21110, 28110. Try 160m at 0300 GMT, 10m on the hour, and 15m on the half hour during daylight hours.

AWARDS:

Certificates to highest scoring station in each state, province, country, and GA county. Other certificates as warranted. Plaques to highest scorers outside GA and GA mobile/portables.

ENTRIES:

Logs should show: date/time in GMT, call, exchange sent/rcvd, band, emission type, and multipliers claimed. Checklists appreciated. Include a signed declaration (usual) and mail your entry to Columbus ARC, c/o Jeanne J. Hunting K4RHU, 2701 Peabody Ave., Columbus GA 31904. Entries should be postmarked no later than June 6th. Include a large SASE for results. Note: Novices should designate their logs as such!

VERMONT QSO PARTY

Starts: 2100 GMT May 7
Ends: 0100 GMT May 9

Sponsored by the Central Vermont Amateur Radio Club, the contest is open to all amateurs. The same station may be worked once on each band and mode. Mobile stations may be worked from each new county. QSO Party contacts can be credited toward the W-VT (Worked VT Award) for working 13 of VT's 14 counties.

EXCHANGE:

QSO number, RS(T), and county for VT stations; ARRL section for others.

SCORING:

VT stations score 1 point per contact and multiply by the number of ARRL sections and countries worked. All others score 3 points per VT station worked and multiply by the number of VT counties worked *on each band.*

AWARDS:

Trophies to highest scoring station outside VT and single operator in VT. Certificates to high scorers in each ARRL section/DX and to 2nd, 3rd, and 4th highest scoring VTs. Special certificate, too, for multi-operator and mobile stations in VT.

FREQUENCIES:

Try CW on odd hour and phone on even hour GMT ... 3555, 7055, 14055, 21055, 28160, 50260, 144-144.5, 3909, 7290, 14325, 21375, 28600, 50360, 145.8, 3932.

LOGS:

In order to be eligible, logs or copies should be sent with an SASE before June 15th to: Peter Kragh W1AYK/K2UPD, 170 Summit Ave., Ramsey NJ 07446.

KANSAS QSO PARTY

Starts: 2000 GMT,
Saturday, May 14
Ends: 2400 GMT,
Sunday, May 15

Work each station once per band per mode. Remember that CW and phone segments are separate bands.

EXCHANGE:

KS send RS(T) and county; others send RS(T) and state/province/country.

FREQUENCIES:

Look for CW 55 kHz up from the bottom of the band, and phone 25 kHz above Advanced/General split.

SCORING:

KS stations multiply number of QSOs times sum of states, provinces, and other ARRL countries worked. Others multiply total KS contacts times the number of KS counties worked (105 max.).

ENTRIES/AWARDS:

Awards to top scorers in each state/province and ARRL country. Send logs and comments to: Robert Davis KØFPC, 1857 South 4th, Salina KS 67401. Be sure to include your name and address. SASE is not required for summary of results.

MICHIGAN QSO PARTY

Starts: 1800 GMT,
Saturday, May 14
Ends: 0200 GMT,
Monday, May 16

This year's contest is sponsored by the Oak Park ARC. This year phone and CW are combined into one contest. MI stations can work MI counties for multipliers. A station may be contacted once on each band/mode. Portable/mobiles may be contacted as new contacts each time county changes.

EXCHANGE:

RS(T), QSO number, QTH – county for MI; state or country for others.

FREQUENCIES:

Phone – 1815, 3905, 7280, 14280, 21380, 28580; CW – 1810, 3540, 7035, 7125, 14035, 21035, 21125, 28035, 28125. 1600 to 1900 GMT, try 15m on the hour, 10m on the half hour. VHF – 50.125, 145.025.

SCORING:

Multipliers are only counted once. For MI stations: 1 point per QSO times (states + countries + MI counties). KL7 and KH6 count as states. VE counts as a country. Max. multiplier = 80. Non-MI: QSO points times MI counties. Max. multiplier = 83. QSO points = 1 point each MI QSO, 5 points each MI special event station QSO (no ITU suffixes). VHF-only entries, same as above, except multipliers per VHF band are added together for total multiplier.

AWARDS:

Only single operator entries qualify. Several trophies, plaques, and certificates will be given, as appropriate.

ENTRIES:

A summary sheet is requested, showing scoring and other pertinent info (name and address in *block letters*, and a signed declaration that all rules and regulations have been observed). MI stations include club name for combined club score. Results will be final on July 30th, and will be mailed to all entries. Mailing deadline

CALENDAR

May 7-8	Triple Letter QSO Party
May 7-9	Georgia QSO Party
May 7-9	Vermont QSO Party
May 14-15	Kansas QSO Party
May 14-15	Mass. QSO Party
May 14-16	Michigan QSO Party
May 15	World Telecommunications Day – Phone
May 22	World Telecommunications Day – CW
June 4-5	IARS/CHC/FHC/HTH QSO Party
June 11-12	ARRL VHF QSO Party
June 18-19	West Virginia QSO Party
June 25-26	ARRL Field Day
July 2-3	QRP – Summer – Contest
July 4	ARRL Straight Key Night
July 9-10	IARU Radiosport Championship
July 16-17	Apollo II 8th Anniversary Contest
July 16-17	10-10 Net Summer QSO Party
Aug 20-21	New Jersey QSO Party
Aug 20-21	Worldwide SARTG RTTY Contest
Sept 10-11	VHF QSO Party
Oct 1-2	Open CD Party – CW
Oct 15-16	Open CD Party – Phone
Oct 15-17	Manitoba QSO Party
Nov 5-6	ARRL Sweepstakes – CW
Nov 13	OK DX Contest
Nov 19-20	ARRL Sweepstakes – Phone
Dec 3-4	ARRL 160 Meter Contest
Dec 10-11	ARRL 10 Meter Contest

is June 20th, to: Mark Shaw WA8EDC, 3810 Woodman, Troy MI 48084.

During MI week, May 14 to 21, all MI QSOs may be counted toward the following awards/certificates offered by the governor of MI:

1. A MI ham submits log info and names/addresses of 15 or more contacts made with out-of-state or DX hams with information regarding MI.
2. An out-of-state ham submits log information and names/addresses of at least 5 MI hams who related facts to him about MI (includes VEs).
3. Foreign ham (excluding any resident of Canada) submits the call letters and name/address plus log information for at least one MI ham who has told him about MI.

Only QSOs made during MI Week, May 14-21, will be considered valid. All applications for certificates must be postmarked by July 1st and mailed to Gov. William Milliken, Lansing MI 48902.

WORLD TELECOMMUNICATIONS DAY CONTEST

Phone
0000 GMT to 2400 GMT,
Saturday, May 15
CW
0000 GMT to 2400 GMT,
Saturday, May 22

Sponsored by the Brazilian Ministry of Communications, this contest has been instituted in order to commemorate yearly the "World Telecommunications Day" (May 17th). Each participating radio amateur will attempt to make the highest possible number of contacts with the different ITU zones of the world in order to enable his country to win the ITU trophy. All bands, 160 to 10 meters, and all modes, phone/CW, may be used. Categories include: single op, multiband, fixed or mobile in maritime ITU zones 76 to 90, clubs/associations as multi-op/multiband.

EXCHANGE:

RS(T) and *ITU zone.*

SCORING:

Contacts with stations in same country = 0 points. Different country, same ITU zone: 10-40m = 1 pt., 80 and 160m = 2 pts. Different country, different ITU zone, same continent: 10-20m = 2 pts., 40m = 3 pts., 80 and 160m = 4 pts. Different country, different ITU zone, different continent: 10-20m = 3 pts., 40m = 5 pts., 80 and 160m = 6 pts. Final score is total QSO points times total number of different ITU zones. Same station may be worked on different bands for additional QSO points, but multipliers only count once regardless of bands. The country score will be the sum of the top five scores from the country on each mode.

AWARDS:

Gold, silver, and bronze medals will be awarded to the three highest scoring stations in the world on each mode. Diplomas will be awarded to the three highest scoring stations in each country on each mode. For countries with high numbers of entries, diplomas to the top three in each call area.

ENTRIES:

Separate logs for each mode and must show time/date in GMT, exchange, band, multipliers, and QSO points. Include a summary sheet. Logs must be postmarked before June 30th and addressed to: LABRE, UIT Contest Coordination, PO Box 07-0004, 70.000 – Brasilia, DF, Brazil.

SAN JOSE BICENTENNIAL AWARD

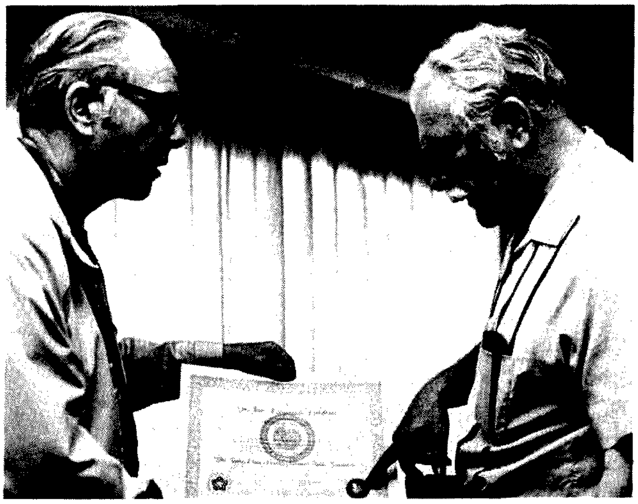
The handsome 3-color certificate of award offered by the Santa Clara County Amateur Radio Association to celebrate the 200th anniversary of the founding of San Jose, California, will now be easier to earn for ham radio operators outside the continental United States. For such stations, point values have been doubled over those originally announced when the certificate first became available. This change was made in recognition of the present low level of sunspot activity and consequent low level of casual DX activity.

The San Jose Bicentennial Award is given to all stations requesting it who accrue a total of 200 points, according to the table below. The list of stations worked must include a specified minimum number of SCCARA members (given in parentheses in the table) and may include contacts with either of the SCCARA club stations, W6UU or W6UW, other stations in the San Jose area (Santa Clara county), and stations outside of Santa Clara County but in the Pacific Division of the ARRL.

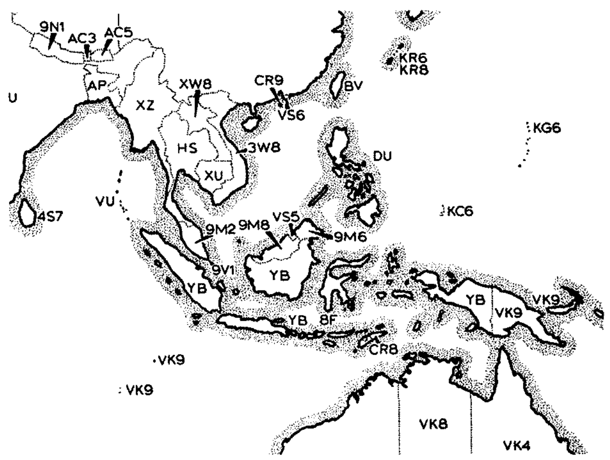
TABLE OF POINTS

From outside cont'l U.S.:	
W6UU or W6UW	100 points
SCCARA Members	50 (2)
Other S.C. County	4
Pacific Division	2
From 6th District outside S.C. County:	
W6UU or W6UW	20 points
SCCARA Members	10 (5)
Other S.C. County	2
In U.S., outside 6th Dist.:	
W6UU or W6UW	50 points
SCCARA Members	25 (2)
Other S.C. County	2
Pacific Division	1
From inside S.C. County:	
W6UU or W6UW	10 points
SCCARA Members	5 (10)
Other S.C. County	1

Applicants for the award should send their list of stations worked, with pertinent log data (no QSLs necessary) to the club secretary at SCCARA, PO Box 6, San Jose CA 95103. With the application, include $1.00 U.S. or 5 IRCs to cover part of the cost of preparation and mailing.



Bill Vette K6TXR was the designer of the San Jose Bicentennial Award certificate. Here he shows it to Dick Barrett W6CFK (on the left). Dick originally proposed that the club issue the award.



Southeast Asia, amateur prefix style. Thanks to Old Man, *the Bulletin of Swiss Short Wave Amateurs.*

RESULTS

RESULTS OF THE 1976 EUROPEAN DX CONTEST, WAEDC – RTTY
Trophy winners:

CT1EQ – Europe single op	W1MX – North America multi-op
I1PYS – Europe Multi-op	DJ4KW/4X – Asia
WAØYDJ/4 – North America single op	I3-13018 – SWL

Of 41 entries listed in the results, only 3 were from the US, in the single op category – How about a little more activity next year?!

Briefs

from page 18

isn't capable of handling the hundreds of complaints, and those who have nothing more than canceled checks to show for their Trigger orders may well have to hire their own lawyers to get their money back. The Illinois AG brought charges against Treger last year, but ran into delay after delay in seeking a court ruling. But, now that the court seems ready to act, Assistant AG McPhee's work is far from over. Next he must begin preparations for answering the hundreds of people who have filed complaints, and help them (or their attorneys) collect. "The trouble with my job," McPhee told *73*, "is that the work only really begins after the trial is over."

Recent interviews with FCC field office officials indicate that since the elimination of license fees early in 1977, the amount of prospective amateurs failing exams has drastically increased. Here are some results from a western office early in February: Technician – 5 passed, 4 failed; General – 3 passed, 15 failed; Advanced – 16 passed, 0 failed; Extra – 1 passed, 4 failed.

Thanks to the *West Coast DX Bulletin*: The FCC has reportedly clarified how to measure Novice power. Now the measurement must be all power into the final tube (exclusive of heater power). Thus a screen-grid final must not only include the plate input power but also the screen-grid input power. The *Bulletin* also reports that the Marconi Memorial Station, II4FGM, is usually active on weekends between 1600Z and 1800Z. That's 20 and 15m SSB and CW. QSL to I4BFY or PO Box 3113, Bologna, Italy.

We stand corrected on our March new product review concerning the Hy-Gain 3750 transceiver. We reported it to be the most expensive amateur transceiver available, but as K4AVU points out, the Collins KWM-2A is priced at $3533, nearly $1500 higher than the 3750.

All eyes had begun to focus on Dayton at deadline . . . the April 29, 30, May 1 extravaganza will hold quite a few surprises in the way of equipment and ham radio politics. It will also mean the naming of "The Radio Amateur of the Year" and "The Specific Event Achievement Award," aimed at one or more radio amateurs for participation in an outstanding event associated with ham radio during 1976. See you there!

IRS (the Interstate Repeater Society) auction in Nashua NH. The 73 booth is at the left center with Technical Editor Rich Force WB1ASL, Executive Editor John Molnar WB2ZCF, and Marketing Director Sherry Smythe hard at work.

Until recently, very little two meter coverage has been available on a large section of the Pennsylvania Turnpike, one of the most heavily traveled routes in the country. That's been changed, with the arrival of WR3AIZ, a 147.75/147.15 machine now operating from Blue Knob mountain, 17 miles southwest of Altoona PA.

Turnpike coverage extends from mile marker 100, near Somerset, to mile marker 200, near Carlisle, assuming average power and antenna. The machine is carrier-access and open to all, 24 hours a day.

Sign of the times in Canada: A licensed amateur operating a rig that was cleaned up to DOC recommendations was recently fined $100 dollars in small claims court in Quebec for "inadvertent jamming of radio and TV shows." Four of the man's neighbors filed the complaints, for which he could have been fined a maximum of $1600. The honorary counsel for the Radio Society of Ontario and the counsel for the Canadian division of the ARRL are currently investigating the case.

The Six Meter International Radio Klub (SMIRK) has proposed some interesting changes to the FCC. Assigned RM number 2832, SMIRK has petitioned for all classes of license (except Novice) to be granted CW status between 50.0 and 50.1 MHz, a segment currently reserved for Advanced and Extra. SMIRK argues that their plan would allow more Technicians access to CW practice through operating, since they'd need to add extra equipment to get on the Novice bands recently authorized at HF. Thanks to K5ZMS.

Updating our guest editorial last month on the Buffalo snow disaster: WBEN's lead in rebroadcasting CB and amateur traffic reports on the BC band has been endorsed by the NAB. In a filing with the FCC, assigned number RM-2830, NAB argues that broadcasters are in a good position to use emergency information taken from ham and CB sources for the public good. No opposition is reported.

With the deregulation of repeaters proposed by the FCC, frequency changes will be common. This could mean added crystal expense for users.

Clubs could follow the lead of the Minuteman Repeater Association, which used a "crystal bank" after their users invested in crystals for a repeater whose frequency had to be changed. Regular users of the Stoneham (MA) machine found that QRM from another repeater made copy difficult. All parties agreed that the Stoneham machine would exchange frequencies with a low power CD machine which was primarily used for emergencies. The Minuteman's editor reports that the frequency exchange is working fine.

An experiment in sporadic-E propagation on six meters is underway on the north coast of Brittany, France. A F3THF beacon is on the air at 50.1 MHz. It uses FSK keying at 170 Hz shift. Initial power is 100 Watts, although if no RFI problems are encountered, that will be raised to 1 kW.

The antenna is aimed toward Central America, and should provide the east coast of the United States some coverage. Initial plans are for the beacon to be on the air from May 1st to August 31st each year. Reports should be sent to Ed Tilton W1HDQ, ARRL, 225 Main St., Newington CT 06111. Thanks to the Six Meter International Radio Klub (SMIRK).

"Contestor's Luck" continued, sunspotwise, through the second weekend of the ARRL DX Contest. European signals on the East Coast surpassed the S9+ mark for two consecutive days, March 5th and 6th. Several long-time DXers called it the best 15m conditions in 3, even 4 years! CW weekends weren't bad either, with the first session serving up superb openings on 15m and 10m as well.

New Products

from page 30

200 hours battery life in a small hand-held case. The unit measures dc volts from 100 uV to 1 kV, ac volts from 100 uV to 750 V, dc and ac current from 100 nA to 20 A, and resistance from 100 uΩ to 20 megs. The basic accuracy of reading on dc V is 0.1% ±1 digit. Features of the Model 22 include: hand-held portability, 200 hours battery life (disposable batteries), large .5 inch LCD display, current measurement to 20 Amps, standard size batteries, overload protection, 0.1% basic accuracy, reading hold feature, and rugged construction.

The Data Tech Model 22 digital multimeter has been called the "Ultimate DMM," because no specifications are sacrificed to implement the small case size. The field service engineer can achieve laboratory grade accuracy in a hand-held DMM that can be read in direct sunlight.

The Model 22 is available with disposable batteries, nickel cadmium rechargeable batteries (60 hours operation per charge), or for ac operation. Optional accessories include carrying case, test lead kit, push-to-hold (reading) probe, high voltage probe, and rf probe. The basic selling price of the Model 22 is $234. *Data Tech, 2700 South Fairview, Santa Ana CA 92704.*

HARRISON HOTLINE

A new tollfree "Order Hotline" has been established by Harrison Radio Corporation for amateur radio equipment and accessories ordering. The new number is (800)645-9187. It will be available for use by retail customers, as well as the dealers being serviced by Harrison's "Two-Step" Division. The new WATS number is nationwide, excluding New York State.

NEW HEADQUARTERS FOR AP PRODUCTS

AP Products, Incorporated, of Painesville OH, is expanding its facilities with the addition of a new headquarters building.

The new building at 1382 West Jackson Street in Painesville is now housing the company's Customer Service, Accounting, and Management offices.

The original facility at 72 Corwin Drive, just around the corner, will now accommodate an expansion of the company's Engineering Services department.

Mail to the company can still be addressed to Box 110, Painesville OH 44077. The same phone number is still in use: (216)-354-2101.

Looking West

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

It's been just a couple of months since WR6AMD returned to the air after a two month and five day hiatus. You remember WR6AMD, or rather WR6ABE. It had been abused beyond belief, taken over by a small but inconsiderate group of users who had little or no regard for themselves or anyone else. In desperation, Bob Thornberg WB6JPI had taken the system off the air, restructured its operational parameters, and instituted a rather stringent set of regulations to guide its day-to-day operation. It was to be a "make it or break it" attempt to save a repeater system that had been one of the nation's pioneering efforts in this field. I wrote at that time: "Would it be greeted by a group of enthusiastic people, eager to build a new standard of open format repeater operation, or would the promised vendetta of a selfish few be the key to making WR6ABE go dark forever and perhaps signal the end to open format relay communication elsewhere?"

For all intents and purposes, WR6ABE returned to operation on Wednesday, January 5, 1977, rather than on the first, as promised. They had come on at about 10 am on the first, but went dark again in support of L.A.'s first Repeater Appreciation Week. At about three in the afternoon on the fifth, WR6ABE (now under the callsign WR6AMD) came back to life. The first few days were quiet; I sort of suspected they would be. Repeater Appreciation Week had caught virtually everyone by surprise, and that, not AMD's return, was the main topic of discussion. It started over the weekend — the direct violation of the guidelines to see if JPI and crew really meant business; the jamming of the system with noise, carriers, and at times even music; the mild but noticeable "baiting of the control stations" to see what could be gotten away with. Quickly came the response: first the dropoff of the repeat function, followed by a taped statement that said that in the opinion of the control stations, operation was below the standard set for the system and that a penalty of "x" number of minutes was being exacted. Then came the penalty itself, in the form of system explanation, *QST* bulletins, *HR Report*, etc. The control stations were for real and they did intend to enforce the rules.

It took about two weeks for the control operator baiting to subside; it had been expected and anticipated, and the numerous control stations handled this situation in a way that proved that their choice had been the right one. It did not take long for those who had previously held exclusive title to ABE/AMD's air time to find out that their action would not be tolerated. Soon many lost interest or, as I suspect, did not have the necessary backbone to admit their earlier wrongdoing and outright disappeared. Except for the jamming problem, severe at times, WR6AMD was on its way to becoming a model repeater where good manners and respect for "thy fellow man" was the order of the day. Pride was returning; many old faces were returning; they still return.

Five-thirty weekdays is the time you find out when it all happened in the previous twenty-four hours if you were not around. That's the hour when AMD goes away for a while and is replaced by WA6TDD remote. Bob uses the remote to read a list of the penalties incurred, their duration, and the responsible party. At first many people were put off by this QST — embarrassed, perhaps — but as time has gone on, it has only been the hardcore troublemaker who has been heard to protest. After the first week or so, many of those incurring penalties took the opportunity of this "two-way" QST to express apologies to those they had offended. Yes, indeed, "user abuse" could and was being replaced by "user appreciation and support"; apathy was being replaced with courage. The AMD experiment thus far has been successful; users' attitude adjustment could be accomplished; WR6ABE/WR6AMD could be reborn.

To frustrate jamming attempts, users have been instructed that it is a "major no-no" to acknowledge being jammed, that to do so is to incur the wrath of the control stations. Keeping the system on has to date been far more of a temptation than the acknowledgment of jammers, much to the frustration of those jamming. They could jam, but the audience acknowledgment would not be theirs. Slowly, all but the most dedicated of the jammers either have been caught or have given up in disgust and gone away. After all, it's no fun to jam if you do not get the other guy's goat.

Enter "auto-jam." Around the third week in January, a high speed CW signal appeared at random moments on AMD. How do you T-hunt down a signal that seems to come from everywhere and yet nowhere at the same time? How do you locate a hidden transmitter that operates for about four seconds every ten or fifteen minutes? How, when you think you have located the general area where you think it is, do you pack into some rugged Southern California terrain to locate a needle in a haystack? Sound impossible? Not if you have the tenacity of people like the MWRA T-hunters. It took only three weeks of part-time T-hunting to locate the auto-jam and put it out of service. Actually, it really took about two and a half part-time weekends, for at about three in the afternoon on February 12, Rick WA6VSK literally stumbled over the antenna and proceeded to dig auto-jam out of the ground. It took cooperation, tenacity and an "I-per," but as usual even the most technologically skilled of jamming attempts was again thwarted by some most skilled T-hunters.

Taking on a group of T-hunters as well-trained and skilled as the MWRA group is asking for defeat. A jammer just does not have an even chance. I am convinced that if you hid a transmitter in concrete, threw it to the bottom of the Pacific, and then set out to jam the T-hunters as well, they would not only recover the concrete block, but uncover the identity of the others jamming as well, doing so in record time. I know they can do it; I have seen them take on the roughest assignments and never once be faced with defeat. If it's putting out rf, Rick or someone like him will find it.

The Procrastination Will Get You Everything Department: God bless the ARRL — they never make a mistake. You know what I mean ... like incentive licensing and the like. Now they're making sure not to make another mistake, by involving themselves in any form of national band planning that they cannot completely control from HQ in Newington. At a time when the amateur community needs direction and guidance in this, especially with 21033 looming on the horizon, where is the Newington crowd? The answer, to me, is quite obvious.

When their very own questionnaire proved beyond a shadow of a doubt that the amateur FM community would not be ruled with an iron hand from HQ, when the concept of an ARRL-appointed coordinator for each area was given thumbs down by the majority of us, when ARRL membership was made a necessity for appointment to a coordinator's job, the amateur community was smart enough this time to tell them to get lost. So rather than looking at the input they had gathered and acting accordingly, the good old League took their well-known ostrich approach and spent the past year skillfully dodging the issue. In fact, they still might be in a position to keep dodging if 21033 had not come along. Now, there are a lot of us who will not let them dodge any longer. It's a good number of months now since that matter was returned to committee for further study, and I, for one, want to know exactly where they stand.

Hey, Newington, wake up! The world outside does keep on moving, and if you wait, you are going to find yourselves left out in the cold. We have no intention of having you play God and appoint whom you wish on a political level to run things for us. Many places already have things running quite smoothly, and what we want is liaison with other groups and individuals doing similar work. We do not want any super ARRL-appointed head stepping in from left field to try to tell us how things should be done. You have but two choices: Either provide the necessary liaison between coordinating councils, or step aside so that someone who is more qualified can do your job for you. 21033 has a lot to offer, but it cannot work unless there is total open and ongoing communication and cooperation between those involved in coordination efforts. Next month or next year will be too late. Now is the time that necessitates action, and if you are not going to act as a representative to all amateurs, members and non-members alike, I can assure you that there are others who will be happy to do so without you. If, as you claim, you represent all amateurs, you will find a way to build some structure of national band planning that *represents* the views and needs of *all* amateurs involved in relay communication. It's your obligation to do so!

Unlike the rather normalized form of operation that one finds on the low bands, amateur relay communications is ever changing and seeking new horizons. In the next few years, there might conceivably be "repeaters" on satellites in synchronous orbit providing worldwide HT coverage. The technology of relay communications is ever advancing, and along has come a breed of amateur that has no time or patience for those who procrastinate. Newington, if you have no intention of taking on this formidable job, please make your intentions public now so that those of us who are concerned with the future can start building the framework of something that will forever bind all amateurs together. We realize the real impact of total repeater/remote deregulation, and are prepared to take on the responsibility. Are you?

In the June, 1976, issue of this magazine, I authored an article titled, "A Representative Democratic Republic," which in essence presented a basic structure for a national/international band planning council that gave a voice to virtually every concerned amateur and every special interest group. If you have not read it, back issues are available from *73* at a nominal fee. That's issue #188 for those of you who file numerically. I do not propose or hope to propose that I have all the answers, or that this idea is the ultimate solution to our current and future problems. I do say that it is a fairly well-conceived groundwork, built on your input, and from which the ultimate solution might be obtained (with probably a lot of modification to suit regional needs). If you are truly concerned about the future, please take another look at this article, find its faults, and suggest alternatives. See if it or something like it could be worked into the structure of your area. Feel free to tear it apart word by word and idea by idea, and restructure it. Then let us know where you stand. A year ago when it was published, a small need for something along those lines existed, but 21033 makes that need into a dire one. To date, this has been the only comprehensive band planning attempt yet fielded. I know that there are many of you out there with even better ideas, but unless you put them down on paper and let Wayne Green or myself know exactly what you feel, we can do little except present our own ideas, and hope that they satisfy your needs today and in years to come. If the ARRL feels like procrastinating on this subject, let it. VHF, UHF, FM, and repeaters have always been treated by them as a stepchild,

anyhow. We just might be a lot better off keeping them out of it and for once standing up to be counted for ourselves. I sincerely believe we have that ability at our fingertips — if only we would bury our personal apathy for a few moments to sit down with a pen and express ourselves. 21033 places our destiny in our hands, for better or worse. If it gets to the report and order phase intact, which it conceivably might, then it will open up a Pandora's box that we must be ready to accept and help guide. We at *73* are ready and willing to accept our share of the responsibility. We suspect that those of you reading this feel the same, in that you recognize your share of the burden. This leaves but one unknown entity, the ARRL, and it's anyone's guess as to where it stands.

The 220 Department: How many 220 repeaters are there where you live? Would you believe that here in the southland there are already 35 in operation, of which 25 are open systems? Eighteen others are in test status, and if you count the two channel pairs being held open for Mexico and the 223.00/224.60- repeater test channel, you will note that all 220 channel pairs are assigned (with the majority in day-to-day use). In the two and a half years since Bill DuHaime WA6NTW placed the first 220 FM system into operation, 220 has grown to a point where it is starting to approach the 146 MHz spectrum crunch.

How crowded is 220 really getting out here? There are times of the day when 223.5 is as crowded as .52 or .94 on two, and if the growth of this spectrum continues at its present pace, we might have to consider 10 kHz (shudder) splits in the foreseeable future. Let's put it this way: We are doing our part out here to thwart any attempt at 220 MHz Class E CB. If you have the activity level we have, then you have done your part, too. If not . . . what are you waiting for? Remember our motto: "220 — USE IT OR LOSE IT!"

The Six Meter Department and Other Things: Six meters for the most part is still a veritable wasteland FM-wise. As you are probably aware, our local council that coordinates six, 450, and above is diametrically opposed to the band plan dictates of Newington, and has adopted and implemented its own coordination plan for six meters. Rather than the 1 MHz ARRL plan, SCRBBA coordinates on what they feel to be a far more technologically competent 220 kHz plan. However, it's the same old TVI bugaboo that instills fear into the hearts of many a potential six meterite that I consider the prime reason for the lack of activity on six (rather than any band plan conflict). By the way, SCRBBA is anxious to share their views and technology with those interested, and an SASE to the Southern California Repeater and Remote Base Association, PO Box 5967, Pasadena CA 91109, may well bring some rather interesting reading material. In fact, whenever you write anyone listed herein for info, I suggest including an SASE to help defray costs to these organizations and individuals. Especially with the cost of postage these days!

Interest in UHF fast scan ATV is growing, as is the membership of the Southern California ATV Club. With better than sixty members, plans are in the works for a crossband 450 to 1250 ATV repeater for this area — possibly from Mt. Wilson. The crossband mode was selected so as to cause an absolute minimum of problems to adjacent narrow band voice communication, which is the prime communication mode on that band in this area. No date has yet been announced as to when this project will be completed, but it is hoped that by repeating 450 to 1250, ATV and narrow band FM will be able to totally coexist and at the same time interest ATVers in experimenting with this mode on bands other than just 450. Input will be in the same 435-plus area as well as other ATV systems, but output has yet to be pinned down specifically. An SASE to the SOCAL ATV Club should bring some info as to what they are doing and what their plans are. The address is So. Calif. ATV Club, c/o John Ruckert WB6ZPN, Secretary, or Ernie Williams WA6BAP, President; both are good in the callbook.

The Sears and the Two Meter Radio Department: OK, guys and gals. Why all the huff? What is the difference between going to your favorite radio emporium or to Sears, Roebuck and Company to buy a two meter radio? Why is it OK to mail order such a piece of equipment from a dealer in another city, but a no-no for a company with the high credibility factor of the Sears organization to even consider selling equipment for that which we hold so dear? Are we starting to run scared of our own shadows?

I, for one, cannot accept this double standard for a number of reasons. First, the rampant paranoia that says Sears selling two meter equipment will put my radios into the hands of those not licensed is totally ridiculous! Has any salesman in any radio store ever asked you to present your license before he sold you a rig? It's never happened to me. If a person intends to get hold of a piece of amateur equipment for illegal use, it won't matter where he goes to buy it. There is no law that states that one must have a valid license to own a piece of amateur transmitting equipment — only to use it. If a person is going to violate the amateur rules and regulations, then it really makes no difference who sells him the radio, does it?

Secondly, how many advertisements carry a specific disclaimer stating that a specific minimum grade of amateur license is required to operate such equipment? The Sears advertisement in the spring/summer catalog, page 967, sure does. It spells it out in very specific terms that anyone can understand. It states specifically that a Technician, General, Advanced or Extra grade license is required prior to transmitting with the unit. Score one for Sears! Again, this goes along with the very high operating standards that the Sears organization adheres to, standards that have made Sears the world's most respected mass merchandiser.

Then, too, there is the most important aspect of this move by Sears back into the amateur radio marketplace. To me, it signals a rather bright future for the overall amateur equipment market. Remember, Sears did not get to the position it holds in the mass merchandising marketplace by making mistakes. They are at the top because they have good business sense. They see what I see: a new and substantial growth period for the amateur service. They are willing to take on the sale of amateur equipment once again. To me that says we are well on the way to what many of us have been working toward for the past two years: an unexcelled overall growth in the number of licensed amateurs (resulting in the increased numbers we will need to hold our own at the 1979 WARC in Geneva).

There are a few other good points that some of you might not be aware of in relation to Sears. First is the fact that Sears services what they sell, so amateur radio will be enjoying something it never had before. The ease of obtaining the necessary parts and service should a rig run amok some day. How easy? As easy as locating the nearest Sears service center or catalog store. Sears happens to run the world's largest organization, and they are located everywhere. In fact, they're only a phone call away. Have you any idea what having this type of service backing a product means?

Then, too, there is the basic creed of the Sears Roebuck organization — which is the simple policy of "Satisfaction Guaranteed or Your Money Back." This is a policy that is fol-

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz.

OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz.

Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

lowed by all Sears stores and service centers. Few others offer that or anything near it. In today's marketplace such a policy is unheard of, yet Sears lives with it and by it.

So before writing all those letters to Wayne Green and the rest of the staff protesting about Sears or any other large retail chain selling amateur equipment, sit down and think for a moment. If you do, you might realize as I do that Sears re-entering the amateur radio marketplace is really a sign of good times ahead. We need Sears and anyone else who is willing to involve themselves in such a righteous manner. In fact, if everyone lived up to the high marketing standards of Sears, we would have little to worry about.

The WR6AKG Department: Well, friends, as I write this, the first amateur repeater devoted primarily to this city's school children has become a reality. About 24 hours ago, Keith Glispie WA6TFD, its builder/backer, "through the big switch" and two meters, bad a new form of amateur repeater born here in the southland. While credit for the very inception of AKG goes directly to Keith and those who worked with him on the project, one must not forget that it was a cooperative effort also involving the Dorsev High Amateur Radio Team, the Southern California Repeater Association (with Bob Thornberg WB6JPI, its chairman, and Jim Hendershot WA6VQP, of its two meter technical committee), and the people of the Los Angeles Unified School District. It was a cooperative effort across the board, and in my opinion each of the groups involved must be given proper recognition for the part that it played.

Though AKG is on the air at last, it is in what we term "test status," and has yet to move into its permanent home atop the Baldwin Hills. In the meantime, there are still a few kinks to iron out, including that of a RACES group that let it be known that Keith's input was their RACES channel only after AKG went on the air. With all the pre-publicity that AKG garnered here and elsewhere long before it ever came on the air, and with the actual channel pair published in this column a few months back, I am at a loss to explain why the RACES group waited until after AKG went into operation before letting anyone know that they were using the channel. However, I feel that this should be easy to solve, in that either the two can coexist (perhaps with the RACES group using the AKG facilities for its drills and operations) or an operational schedule can be arranged to meet the needs of both. However, the most important step is to get the RACES people and the AKG people sitting down over a cup of coffee for a good rap session. It never fails to amaze me what can be accomplished once people, even hams, learn the art of personal communication. However, it should be noted that such incidents as this could easily be avoided by having non-relay special interest organizations such as RACES groups, AREC (ARPSC) groups, and the like attend and take an active part in the many open meetings held by local repeater and FM councils (such as SCRA and SCRBBA). There is absolutely no way for any coordinating council to know if a channel is in use by a non-relay special interest group unless that group makes an effort to let the rest of the world know it exists. I must ask if it is really that hard for a non-relay group to find a warm body or two who are willing to attend such meetings so as to initiate good ongoing communication with the rest of those using the spectrum. Only such cooperation and communication can avert a reoccurrence of this unfortunate happening. I can speak for the SCRA when I tell you that not only are their quarterly meetings open to all interested amateurs, but also that they invite those truly interested but who are not repeater owners to become active in the organization by obtaining associate membership. They invite open dialogue between repeater owners, users, and other non-relay special interest groups, as they realize that it is only through such dialogue that all spectrum users can benefit.

Anyhow, that really does it for the AKG story: from the idea of an ex-high school student who saw a need to a service to the younger generation of Los Angeles amateur operators. We have all been a part of amateur radio history; we have watched it develop from the embryo of an idea to the reality of today. We can all take pride in the corps of devoted citizens, amateur and non-amateur alike, who worked shoulder to shoulder to give repeater communication a truly new meaning and direction. Looking West salutes them all.

Build the World's Simplest Keyer

- - uses 555 timers

Andy Ring
49 Main St.
Yarmouth ME 04096

This keyer is simple and inexpensive to build. The NE555 timers will cost .50 to $1.50 each depending on the source of supply. Your local Radio Shack calls it a 276-1723 and will charge you $1.49. If you like, you can use a dual timer called a 556 (Radio Shack 276-1728). The only difference will be that both timers are in one package and V+ and V- connections are common to both timers. See the specs that come with your IC for pin connections. All other components can probably be found in your junk box. The keyer has no memories but the characters are self-completing and are fully adjustable not only in speed, but length of character as well. The key must be two

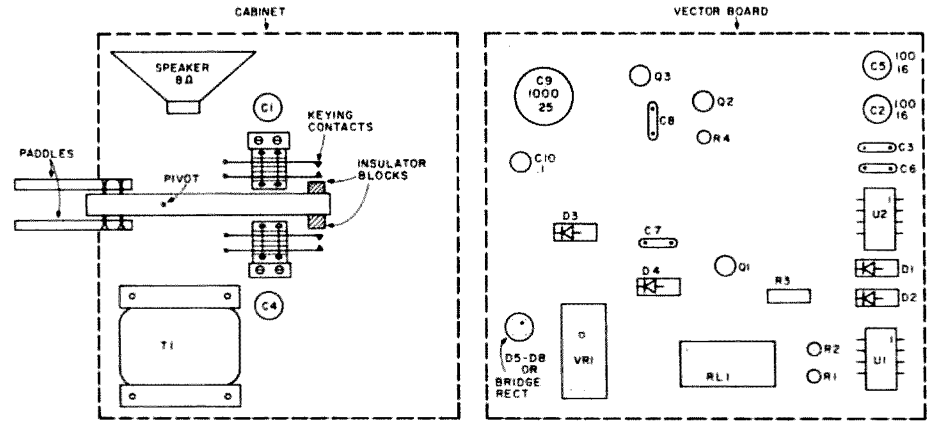

Fig. 1. R1, R2 — 330 Ohm, ¼ Watt; R3 — 10k, ¼ Watt; R4 — 56k, ¼ Watt; C1, C2, C4, C5 — 100 uF, 16 V electrolytic; C3, C6 — .01 uF; C7, C10 — .1 uF; C8 — .05 uF; C9 — 1000 uF, 25 V electrolytic; RA, RD — 1k linear taper pot; RB — 500 Ohm linear taper pot; RC — 10k linear taper pot; D1-D8 — 1N4004 or equivalent 400 V piv, 1 Amp; Q1, Q2 — 2N2222 NPN; Q3 — 2N5964 PNP; RL1 — 12 V reed relay; VR1 — 12 V positive regulator #7812; T1 — any 15 or 20 V power transformer 500 mA or more.

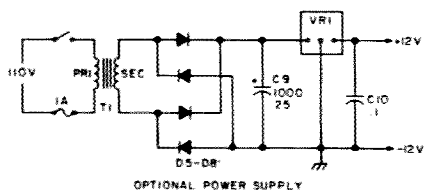

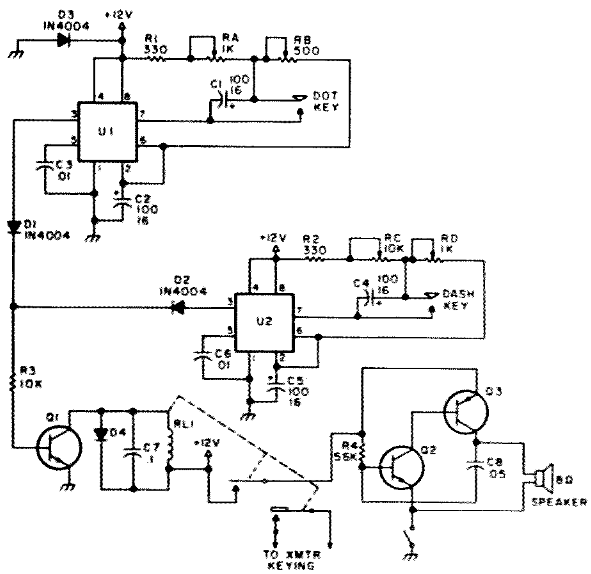

Fig. 2. T1 — 15 to 20 V sec at 500 mA; D1-D8 — 1N4004; VR1 — #7812 12 V 1A positive regulator; U1, U2 — NE555 timer IC; RL1 — 12 V reed relay DPST; Q1, Q2 — 2N2222; Q3 — 2N5964; all resistors ¼ Watt.

SPST switches. The standard SPDT key will not work.

How It Works

When the dot key is closed, U1 becomes an astable multivibrator. The speed of the multivibrator is determined by RB, and the duty cycle or length of the dot is determined by RA. When U1 is turned on, pin number 3 is high, causing Q1 to turn on and close relay RL1. D1 and D2 are necessary because when U1 is high, U2 is low, so pin 3 of U1 must not be tied directly to pin 3 of U2. Most reed relays available on the surplus market today are 3 pole single throw. One set of contacts is used to drive the monitor oscillator consisting of Q2 and Q3, while one or both of the remaining contacts (2 wired in parallel will handle more current and is more reliable) are used to key the transmitter. The operation of U2 is identical to U1 except the timing and length of character.

Construction

There are no special construction considerations except the key as mentioned earlier. I constructed mine on a 2" x 4" piece of vectorboard with .1 inch spacing. This is available at Radio Shack also and can be purchased in several different sizes and cut to desired size with tin snips. The whole keyer is constructed in a 2½" x 5" x 6" box. The 12 volt supply may be taken from your transmitter or the power supply shown may be used with all except the transformer mounted right on the vectorboard. There is ample room in the box for a small 15 to 20 volt transformer. 400 or 500 mA will be sufficient as the keyer draws only approximately 50 mA key closed. A push-button switch is provided to shut off the monitor in case your transmitter has a sidetone monitor of its own. ■

Stop That Autostart

- - mods for the ST-6 circuit

Rick Bourgeois, M.D. WA5EVH
PO Box 2746
Lafayette LA 70502

The ST-6 autostart is nice when used in the amateur bands, but doesn't help much when one wants to copy commercial stations that do not drop their carriers when not transmitting any text. As long as there is a mark tone, the ST-6 stays in receive with the motor on. Mechanical motor stops work okay except in noisy conditions. Since the ST-6 stays in receive with a steady mark, any fading or noise keys the loop and the mechanical motor stops just cycle off and on.

However, the circuit shown in Fig. 1 solves the problem.

How It Works

The versatile 555 IC timer is the heart of the circuit. The timer output, pin 3, goes to the input of the ST-6 op amp 5 (OA-5). Normally during receive, pin 3 is high and blocked by D1 so that nothing happens. While RTTY is being received, trigger pin 2 of the IC is drawn low through D2 and starts the timer, but C1 is also kept discharged by this same line through D3 and the switching action of Q1. This prevents C1 from charging and the timer output stays high. Once FSK reception stops, however, and a steady mark tone remains, C1 is allowed to charge up. After a predetermined interval, pin 3 drops to low; this pulls the input of OA-5 low, effectively mimicking a loss of signal condition.

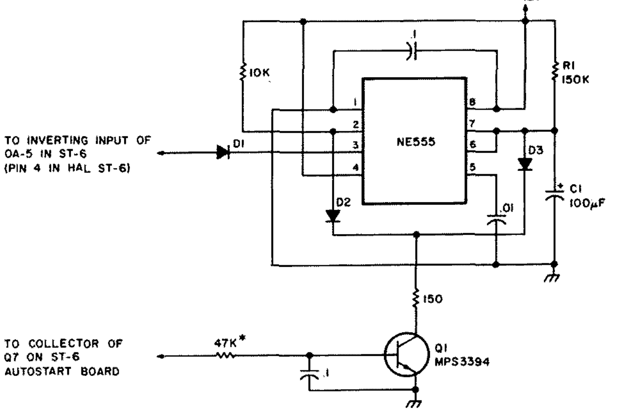

Fig. 1. Time delay (in secs.) = 1.1 x R1 (Ohms) x C1 (farads).
**Increase to 56k if Antispace fails to operate.*

The ST-6 now goes into standby and the regular "motor off" function occurs as usual. The motor remains off until valid RTTY again appears. Note that no previous function of the ST-6 has been compromised, but now the ST-6 goes into standby and the subsequent "motor off" condition with a steady mark as well as with a loss of signal condition. A time of 15 seconds works well, since this, added to the 25 seconds of the ST-6 delay, gives about 40 seconds to turnoff in the presence of a steady mark. An additional added benefit is that the ST-6 now can screen the signal for the presence of valid RTTY before the motor again turns on.

The circuit can be built on a small PC board, and is mounted directly onto the ST-6 Autostart/Antispace board. Only three connections other than ground are required.

If you spend much time copying things like the weather and press, do your printer a favor and give it a rest with this nifty little circuit added to your ST-6. ■

Predict the Weather!

- - a complete satellite receiver

Ralph E. Taggart WB8DQT
602 S. Jefferson
Mason MI 48854

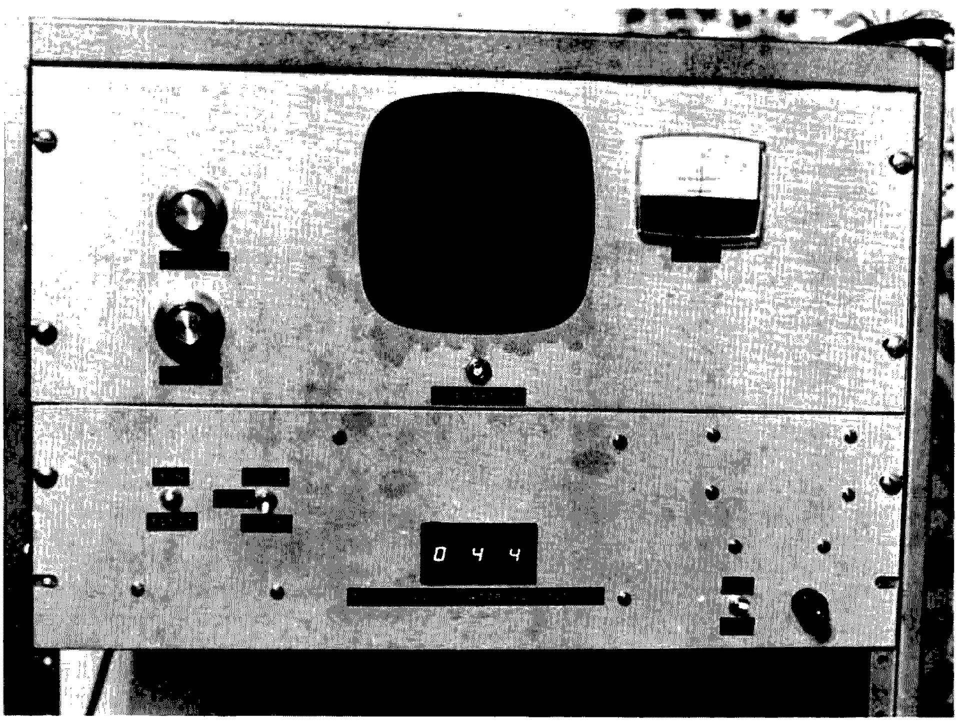

Fig. 1. The author's satellite receiver. The RX-144 modules are mounted in a minibox with the squelch and volume controls on one end. The box is mounted on its side behind the rack panel, secured to the panel by the control nuts of the volume and squelch controls. The signal strength meter and speaker plug into phono jacks at the other end of the minibox. Two other jacks on the same end of the box provide for the 12 volt input and the low level output to the tape recorder. The BNC receptacle is also located on the exposed end of the minibox. The headphone jack illustrated is optional, but does help keep the rest of the family asleep during early morning satellite transmissions. A shorting ¼ inch phone jack in the speaker line is all that is required. The panel below the receiver contains a rack mounted version of the digital orbital timer described previously in 73 and also in the Weather Satellite Handbook. *The timer is programmed for NOAA 4 which was 44 minutes into an orbit when the photo was taken. Since the photo was taken in the morning, the satellite should have been audible on the receiver. If the photo reproduces well, you can see from the signal level meter that indeed it was!*

One of the most important pieces of equipment in the weather satellite station is the receiver that actually picks up the satellite transmissions. The *Weather Satellite Handbook* (available for $4.95 from *73*) outlines several approaches to the receiver portion of the station, including custom receivers available "off the shelf," modification of commercial monitor receivers, availability of kits, and conversion and utilization of surplus equipment. The purpose of this article is to describe the construction of a complete satellite receiver using a readily available kit. Before we start on the details, however, it would be useful

to briefly review the desired characteristics of receivers for satellite service. These characteristics involve mode and bandwidth requirements, sensitivity, frequencies, and various operating conveniences that complement the operation of the satellite station. I will briefly outline some of these requirements and then show how the typical home brew addict can achieve the desired performance.

Frequencies

Two frequency ranges are currently in use for various weather satellite operations – the 135-138 MHz VHF satellite band and the 1691 MHz S band frequency used by the new series of GOES geostationary satellites. If operation in both frequency ranges is contemplated, the logical approach is to begin with a quality VHF receiver and add on the S band capability in the form of a converter. As noted in a previous review article, the S band converter problem is a hard nut to crack, but there are some exciting developments afoot in this area and you can count on the fact that *73* will carry the details on a suitable converter once the system is to the point where it can be readily reproduced. In this article, we will describe a basic VHF receiver which is packaged so the S band converter can be added at a later time.

In the VHF range we are interested in three different frequencies:

135.6 MHz – the ATS geostationary satellites transmitting gridded WEFAX pictures in the APT mode

137.5 MHz – primary frequency for the NOAA polar orbiting satellites transmitting real-time visible light and IR pictures in the 48 line SR mode

137.62 MHz – used once a month for tests with the primary NOAA spacecraft and as the primary frequency for any backup NOAA satellites that are still operational

To insure on-frequency operation when needed, the receiver should be crystal controlled. It may be single channel if your operations involve primarily the ATS or NOAA spacecraft (i.e., 135.6 or 137.5 MHz) or it can be multi-channel with switch selection of all of these frequencies. Since this frequency range is quite close to the two meter band, there should be some useful possibilities for conversion of two meter receiver designs, something we shall take advantage of in constructing the receiver to be described shortly.

Mode and Bandwidth Requirements

The satellite transmissions of interest to us are all FM with a deviation of 9-10 kHz. This means that the basic receiver should have a bandwidth of at least 20 kHz (10 kHz selectivity) in order to accommodate the satellite signal. In the case of the polar orbiting satellites, we have an additional factor to consider – Doppler shift as the satellite approaches and moves away from the ground station. In the case of the VHF satellite range, this Doppler shift is in the order of ± 4.5 kHz. Given worst case Doppler and maximum deviation, we would thus require a bandwidth of 30 kHz (15 kHz selectivity) for a general purpose satellite receiver. This is fortunate, since i-f filters for 30 kHz bandwidth are readily available although no longer standard for most receivers. Most VHF FM operation today is standardized at 15 kHz bandwidth (7.5 kHz selectivity). This is too narrow even to accommodate the deviation of the geostationary satellites, let alone deviation and Doppler shift in the case of the polar orbiters. If such a narrow filter is used, the upper part of the deviation swing will fall out of the

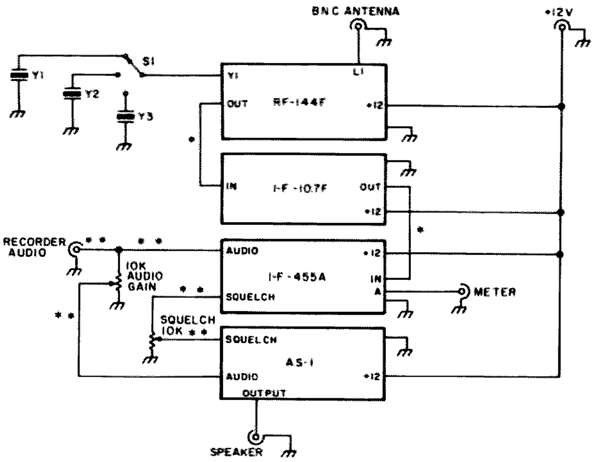

*Fig. 2. Schematic representation of the interconnection of the receiver circuit boards. The kit instructions show the actual location on the boards for each of the connections noted above. The connection between L1 on the RF-144F board and the BNC connector is made with a very short length of the silver-plated wire supplied with the kit. Mounting of the individual boards should assure adequate grounding of each board to the aluminum minibox. Rf connections between boards (marked with *) should be made with the shortest possible lengths of miniature 50 Ohm coax. Connections to the audio gain and squelch controls (marked **) should be made with shielded audio cable. All other connections can be made with ordinary hookup wire. In the case of a multichannel receiver, the wire from Y1 of RF-144F should be routed to the common lug of the crystal selector switch (S1). One lug of each of the three crystals (Y1 – 135.6, Y2 – 137.5, Y3 – 137.62) can be soldered to the switch lugs. The other lug of each crystal can be routed to a common ground connection using the shortest possible leads.*

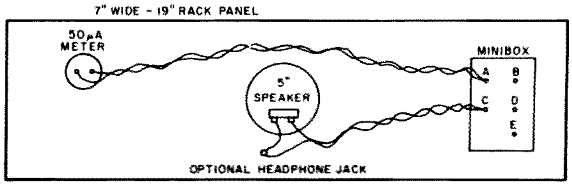

Fig. 3. Diagrammatic representation of the interconnection of the receiver elements on the rack panel. The aluminum minibox with the receiver boards mounts to the panel using the control nuts for the squelch and volume controls. The rear of the minibox contains the four phono jacks (A-D). A is the meter output and connects to the 50 microamp meter on the front panel. The meter leads terminate in a phono plug with the + lead on the center pin and the - lead to the grounded shell. B is the low level recorder output and connects to the tape recorder input with a shielded audio cable. C is the speaker output. Leads from the 5 inch speaker are mated here with a phono plug. If a headphone jack is desired, a ¼" phone jack can be wired into the hot speaker lead – a shorting jack should be used so the speaker is operative when the headphone plug is removed. D is the +12 V plug and is connected to the 12 V receiver supply – +12 V to the center pin of the phono plug and the - lead to the outer shell. E is the BNC connector for the antenna. Ample space remains behind the panel for later incorporation of an S band converter and switching circuits.

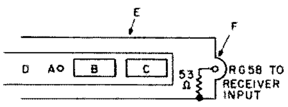
Fig. 4. Diagram of a variable strength 137.5 MHz signal source for receiver alignment. A — SPST toggle switch controlling power to the oscillator; B — 9 V transistor battery; and C — an OX oscillator with a type EX crystal on 45.833 MHz. A, B, and C are attached to the end of a wooden ruler or yardstick (D) which slides in and out of a copper tube (E) with a diameter sufficient to clear the oscillator module. Two feet of tubing is adequate. A coax jack (F) is mounted to a copper or brass partition soldered across the end of the tube, terminated with a 53 Ohm resistor. 52 Ohm coax connects this jack with the receiver input. The signal level of the source can be varied by sliding the oscillator in and out of the tube. Signal level to the receiver will increase as the oscillator is moved toward the pickup end of the tube and will drop as it is moved away. If the receiver is built as a single channel unit for 135.6 MHz ATS satellite service, a 45.200 MHz crystal in the OX oscillator will provide harmonic output on the proper frequency.



receiver passband. In the case of the polar orbiters, you would lose the upper end of the gray scale even when the satellite was overhead, and the signal would be virtually impossible to copy early and late in the pass when Doppler shift would slide most of the signal out of the narrow receiver passband.

Other Features

Since most stations make recordings of satellite transmissions, an audio output connection for this purpose is desirable. Ideally, this tap should be made before the volume control so that changes in speaker listening level do not result in changes in record level. If the receiver has a squelch control (desirable to prevent operator insanity when a satellite is not within range), this feature will also permit continuous recording even if the squelch control cuts in and out due to a tight setting. A front panel signal strength meter is also desirable to help in antenna tracking. The receiver ac supply should have virtually no ac ripple to prevent incorporation of undesirable ac hum on the recorded or real-time satellite signal.

In making the decision to buy, modify, or build in acquiring a suitable receiver, you should be guided by your own inclinations. Building will probably not save you much money, but it will provide you with a receiver with all features tailored to your own needs. After a traumatic move to a new house, I made the decision to convert my sprawling station to a neat cosmetic installation in a desktop rack. Since none of the receivers on hand lent themselves to rack mounting, I decided to roll my own. While strolling about the Dayton Hamvention with the other satellite and SSTV fanatics, I decided to plow some of my ill-gotten gains from the sale of some equipment into the purchase of a VHF Engineering receiver kit for two meter FM. I vowed to use the kit as the basis for the VHF satellite receiver with all of the features I required, leaving enough space to add the S band converter that was already under development. The effort was an unqualified success and really very little effort at all. If you still like to heat up a soldering iron and want a receiver equal to or better than anything you can buy, then read on and discover how it can be done.

THE RX-144 RECEIVER KIT

The heart of the receiver is the RX-144 kit available from VHF Engineering, 320 Water Street, Binghamton NY 13902, for $69.95. Given the performance of the completed receiver, this has to be one of the finest values in the amateur radio market today! Their standard RX-144C kit contains boards and parts for the following sub-assemblies:

(1) RF-144F front end board, providing a crystal controlled front end with 10.7 MHz i-f output. Dual gate MOSFETs are used for the rf amp (MPF-121) and mixer (MPF-122). Squelch sensitivity is rated at 0.2-0.3 microvolts but appears to be slightly better in the "real world." Front end gain is approximately 40 dB with 55 dB of image rejection and 100 dB of i-f rejection.

(2) IF-10.7F board providing two stages of 10.7 MHz i-f amplification using ICs with output at 455 kHz. An input crystal filter (2 pole) sets the system bandwidth. Total gain is in the order of 50 dB and the circuit is unconditionally stable.

(3) FM-455A board with a single IC 455 kHz amplifier providing 30 dB of gain and an IC limiter and FM detector. The board has provisions for a signal strength meter and a zero-center discriminator meter.

(4) AS-1 board, providing squelch and COR functions as well as up to 2 Watts of audio amplification for operation of an external speaker.

In order to build the receiver as described, you will require the additional components listed in Table 1. Some of these relate to the specific packaging scheme which I employed, so you can obviously alter these to suit your own needs. The basic kit is packaged as four individual units, each containing a circuit board and the proper components, as well as a set of layout diagrams, schematics, and instructions for construction and testing of each board. In addition, the kit contains a very complete manual. Where appropriate, departures from kit assembly instructions or additions will be noted for each board.

RF-144F: If the receiver is to be operated on only one channel, the kit instructions should be followed. If multiple channel operation is intended, leave off the socket for the local oscillator crystal (Y1) and solder a length of hookup wire (insulated) to the ungrounded land at the socket location. If the receiver is to be packaged as described later, the input terminal and antenna tap can be omitted at this stage in construction.

IF-10.7F: This board should be wired according to the kit instructions except for the input crystal filter. The filter supplied with the kit is a Piezo Technology 2195F with a bandwidth of 15 kHz. In order to accommodate signal deviation and Doppler shift in satellite service, a bandwidth of 30 kHz is required. The crystal filter specified in Table 1, a Piezo Technology 2196F, has the required bandwidth and should be substituted for the unit included with the kit.

FM-455A: Wire according to kit instructions.

AS-1: Wire according to kit instructions.

When all the boards have been completed, make the usual checks for wiring errors. In case you are tempted to simply bypass the latter step, I will confess that I initially left out a jumper on the 10.7 MHz i-f board and spent several evenings attempting to discover why the receiver wouldn't work!

Fig. 2 shows the basic packaging of the three boards in the minibox specified in Table 1. The boards are oriented cross-wise in the box with the rf board to the rear, followed by the 10.7, 455, and audio boards moving toward the front of the box. The back of the box contains

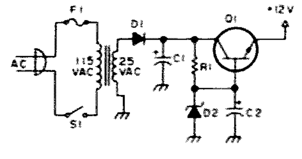
the BNC antenna connector, mounted so that the antenna input tap to L1 of the rf board can be made with a very short length of the silver-plated wire supplied with the kit. The back also contains the 4 phono jacks for the speaker output, +12 V, the S meter output, and the low level audio output to the tape recorder. The front of the box has the squelch and audio gain controls. If you desire multi-channel operation, the crystal selector switch should also be mounted on the front of the box. Fig. 3 summarizes the board interconnections and the connections to the minibox mounted components.

Preliminary Setup

Once the receiver is packaged in the minibox, you are ready for initial checkout and alignment. Connect an 8 Ohm speaker to the SPEAKER jack, the 50 microamp meter to the METER jack, and a 12 volt supply to the +12 V jack. If a calibrated signal generator is available, it can be connected to the antenna input. Applying power should result in typical FM receiver noise output from the speaker. Check the gain and squelch controls for proper operation. Switch S1 to 137.5 MHz and dial up the signal generator to that frequency. The receiver should now quiet. Adjust the signal level so that it drops down to the margin of audibility and proceed to align the rf and i-f boards according to the kit instructions. The name of the game is to keep the signal level down near the noise and keep tweaking for maximum quieting and/or maximum signal level on the meter. What do you do if you can't beg, borrow, or steal a suitable signal generator? The answer is to order a type OX oscillator module with a matching EX crystal from International Crystal Manufacturing Company, 10 N. Lee, Oklahoma City, Oklahoma 73102. The OX oscillator kit and EX crystal for 45.833 MHz will set you back a total of $6.90 for an excellent 137.5 MHz signal source. The problem of keeping the signal level down far enough for alignment can be solved by strapping the oscillator and a 9 V battery to the end of a ruler or yardstick and sticking the whole business into a length of copper tube as indicated in Fig. 4. The tube acts as a waveguide with almost infinite attenuation after several inches. By moving the oscillator toward or away from the pickup end of the tube, you can smoothly vary the signal level to the receiver for alignment purposes. The end result is equal to or better than most signal generators in terms of performance. This rather neat idea is a somewhat simplified version of an idea presented by K1CLL in a previous article in *73*.

Once the alignment is completed, the receiver is now capable of pulling in satellite signals, but let's restrain ourselves and finish the final packaging. Obviously everything can be placed in a cabinet of some sort, but I chose to rack mount the assembly in an attempt to reduce the "sprawl" in the satellite station. A standard 19" rack panel 7" in width was used. Drill holes with the proper spacing to accept the layout of the audio gain, squelch, and crystal switch (if used) placement on the minibox, add a cutout and holes for speaker and meter mounting, and proceed with final assembly. The minibox is attached to the panel by the control nuts. Mount the speaker, speaker grill, and the meter and you are almost finished. The receiver can be powered by an outboard 12 volt supply or a supply can be built and mounted to the back of the rack. Fig. 5 shows a suitable power supply circuit. The layout of my own receiver is shown in Fig. 1. Note that the VHF receiver is offset to one side of the panel. This was to provide room for integration of an S band converter for the SMS/GOES satellites — a goodie that will appear in *73* once I am sure it is at the point where it can easily be duplicated. The meter and speaker connections are made plug-in with phono jacks to provide modularization for connection of other gear if desired. The VHF antenna can be connected to the BNC connector and the 12 volt supply — internal or external goes to the +12 V jack. The RECORDER AUDIO jack provides a low level signal to the station tape recorder that is unaffected by the audio gain setting. As noted in the kit instructions, provisions are made for an outboard COR circuit and a discriminator meter that could be added if desired.

Fig. 5. Suggested power supply circuit. D1 — 2 A 50 piv; D2 — 12 V 1 W zener; Q1 — NPN power transistor (30-90 Watts); R1 — 1000 Ohms ½ W; C1 — 1000 mF/35 V; C2 — 1000 mF/16 V; T1 — 25 V 1 A filament transformer; F1 — ½ A fuse; S1 — SPST toggle switch. Q1 should be mounted on an insulated heat sink. Alternatively, a 12 V regulator IC such as the LM-340-12 may be used to replace Q1, R1, D2, and C2. The IC regulator should have its case bolted to the chassis using mounting grease to provide heat sinking.



Performance

In a word, excellent! The receiver, without an outboard preamp, does better than any previous receiver I have tried with or without preamps. Attaching any of my preamps — and I have some pretty good ones — noticeably degrades receiver performance, indicating excellent low noise performance of the basic receiver front end. No receiver tried up to date, even with added preamps, could deliver a full quieting signal from ATS-3 on my 5 element crossed yagi while ATS-1, located close to the horizon at my location, is barely audible on that particular antenna. The new receiver delivers full quieting signals from *both* satellites on the modest antenna without the use of a preamp. Near-horizon fading of the NOAA polar orbiting satellites is eliminated to the point where the receiver limits as soon as the satellites clear the radio horizon. To say that VHF Engineering has done a superb job is certainly not overstating the case. If you want a first-rate satellite receiver, you can hardly go wrong! ■

4 RCA type phono jacks (Switchcraft 3501 FR or equiv.)
1 BNC panel receptacle (Amphenol 4500)
1 7" x 5" x 3" aluminum minibox (BUD CU-3008A or equiv.)
1 1-pole 3-position rotary switch (if multi-channel operation is desired)
1 50 microamp panel meter (Radio Shack)
1 5" speaker (Radio Shack)
1 5" speaker grill (Radio Shack)
1 7" wide rack panel (BUD PA-1104)
2 10k linear taper panel mounting potentiometers (volume and squelch)
2 or 3 knobs, styled to suit. 2 required for volume and squelch, crystal selection optional.
1-3 crystals for frequencies desired. Third overtone, 20 pF load, HC25/U case style:
41.6333 MHz for 135.6 MHz receive
42.2666 MHz for 137.5 MHz receive
42.3066 MHz for 137.62 MHz receive
1 30 kHz 2 pole crystal filter for 10.7 MHz i-f. Model 2196F from Piezo Technology, P.O. Box 7877, Orlando FL ($10.00).
1 12 volt low ripple power supply or components as listed in Fig. 5.
Misc. hookup wire, solder, etc.

Table 1. Components in addition to the basic receiver kit that are required to complete the satellite receiver.

Learn A New Language!

- - try CW

The familiar term CW rings a bell in every ham's head. Every ham has, at one time or another, learned the Morse code in order to pass a test for his license. But have they actually learned the code, or have they just memorized it?

CW is similar to a foreign language in many ways. For one, it takes countless hours of work to speak fluently in any foreign tongue. Perseverance and motivation are required. Reading and listening will also help in the mastering of a language.

In other words, the "secret" in learning a language is *diligent practice*. There is no other way to escape the practice that is required. I do not want to discourage you from taking up CW as a serious facet of your hamming time. In fact, I am attempting just the opposite. You will make greater gains when you realize the work, time, and energy required.

There are a variety of tapes and records available for the elementary and intermediate CW operator's benefit. These methods work well, and are a good approach to the CW barrier.

Most ham operators send and receive Morse code between the speeds of five and thirty words per minute. At these speeds, the individual letters of each word are deciphered and registered on paper or in our minds. This method is quite acceptable, provided you wish to converse with people at these speeds.

There is, however, a hidden barrier that crops up when you reach approximately thirty words per minute. At and above this speed, you must begin to develop a vocabulary of words. Just as you learned to recognize a letter by its total "phrase," you will have to learn to recognize words by their total "phrases," not by piecing together letters. As the CW is being sent, you should hear words, not individual letters.

How does one acquire this skill? You can practice by tuning in various CW practice stations that operate on a regularly scheduled basis. Schedules of these stations are available from the ARRL. It also helps to have someone send you the more frequently used words and prefixes.

Out of necessity, a person receiving high speed CW will need to learn the art of "copying behind." To practice, just write everything a few words behind what is being sent. By doing this, fewer problems will occur with spelling and capital letters; there will be an overall improvement in the transcription from the mind to the paper.

No matter how fast you may be able to decipher CW in your head, you must be able to transfer it down onto paper if you wish to prove that you have a high proficiency in the translation of CW. There are various organizations which issue certificates for skills in CW proficiency. The Connecticut Wireless Association gives an award to those able to receive and *put onto paper* a 60 words per minute code proficiency transmission. To transfer code at speeds of over 30 words per minute onto paper, a typewriter is needed. Wear headphones as you are typing, so the typewriter will not drown out the CW!

Sending

Most hams cannot send good quality CW above 20 words per minute with a straight key. Therefore, a high percentage of the hams operating CW today use an electronic keyer. Many features are available on a keyer, such as dot and dash insertion, iambic operation, and automatic character spacing. If you desire the most highly advanced and versatile keyer available, then the Accu-Keyer with memory should fill the bill. The 1976 *ARRL Handbook* gives details on how to build this gem. Designed and built by WB4VVF, it has every feature in a keyer a ham could ever want!

If you enjoy typing, you may wish to build or buy a CW typewriter. As you type, CW appears (electrical form!) at the output of this machine. This is an easy method of sending very accurate CW.

As you begin to increase your CW proficiency, you will begin to enjoy this fascinating facet of ham radio more and more. I would be especially interested in hearing from anyone who is able to receive CW at a speed in excess of 60 words per minute. This *is* possible; it just takes practice, practice, practice. ■

A display of early amateur radio memorabilia now at the Pioneer Village Museum in Minden NE.

Amateur radio conventions and regional get-togethers back in the beginning 1920s were real festivities. The spirit which prevailed did so imbue all who attended that a broad new enthusiasm was born and dominated throughout amateur radio land in America.

Reference was made in our last installment to the 1920 grand finale convention in St. Louis. To prove that all the big-wigs, as well as hundreds of the hoi-polloi, were present, here is reproduced that convention's "Programme of Events."

Should any reader who was present have any recollections or recognize any of the "stalwarts" mentioned, I most assuredly would be willing to swap a few yarns.

It would be to the everlasting glory of the proverbial

The History of Ham Radio

-- part III

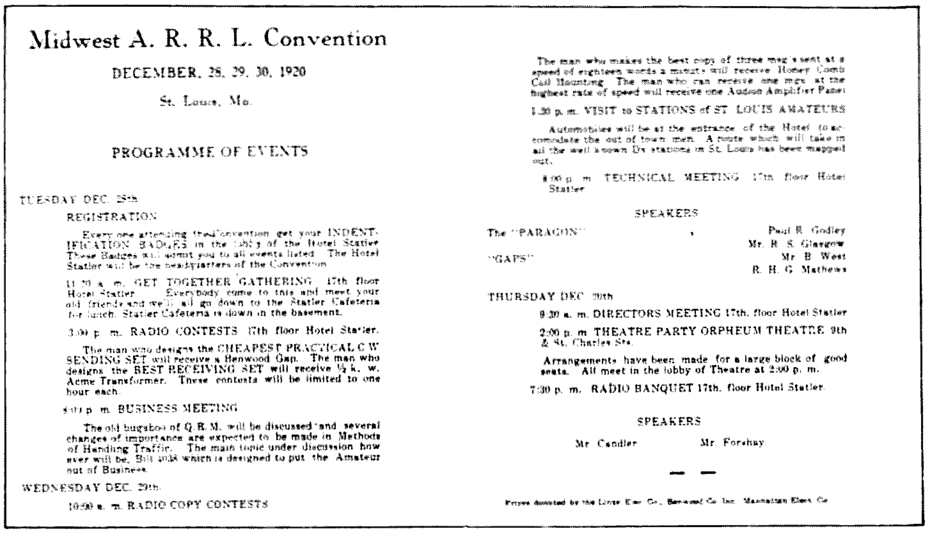
527 Spring Creek Road
Washington IL 61571



Midwest A. R. R. L. Convention

DECEMBER, 28, 29, 30, 1920

St. Louis, Mo.

PROGRAMME OF EVENTS

TUESDAY DEC. 28th

REGISTRATION

Every one attending the Convention get your INDENTIFICATION BADGES in the lobby of the Hotel Statler. These Badges will admit you to all events listed. The Hotel Statler will be the headquarters of the Convention.

11:30 a. m. GET TOGETHER GATHERING 17th floor Hotel Statler. Everybody come to this and meet your old friends and we'll all go down to the Statler Cafeteria for lunch. Statler Cafeteria is down in the basement.

3:00 p. m. RADIO CONTESTS 17th floor Hotel Statler.

The man who designs the CHEAPEST PRACTICAL C W SENDING SET will receive a Henwood Gap. The man who designs the BEST RECEIVING SET will receive ½ k. w. Acme Transformer. These contests will be limited to one hour each.

4:00 p. m. BUSINESS MEETING

The old bugaboo of Q. R. M. will be discussed and several changes of importance are expected to be made in Methods of Handling Traffic. The main topic under discussion however will be, Bill 2048 which is designed to put the Amateur out of Business.

WEDNESDAY DEC. 29th.

10:30 a. m. RADIO COPY CONTESTS

The man who makes the best copy of three msg's sent at a speed of eighteen words a minute will receive Honey Comb Coil Mounting. The man who can receive one msg. at the highest rate of speed will receive one Audion Amplifier Panel.

1:30 p. m. VISIT to STATIONS of ST. LOUIS AMATEURS

Automobiles will be at the entrance of the Hotel to accommodate the out of town men. A route which will take in all the well known Dx stations in St. Louis has been mapped out.

8:00 p. m. TECHNICAL MEETING 17th floor Hotel Statler

SPEAKERS

The "PARAGON" — Paul F. Godley

Mr. H. S. Glasgow

"GAPS" — Mr. B. West

R. H. G. Mathews

THURSDAY DEC. 30th

9:30 a. m. DIRECTORS MEETING 17th. floor Hotel Statler

2:00 p. m. THEATRE PARTY ORPHEUM THEATRE 9th & St. Charles Sts.

Arrangements have been made for a large block of good seats. All meet in the lobby of Theatre at 2:00 p. m.

7:30 p. m. RADIO BANQUET 17th. floor Hotel Statler.

SPEAKERS

Mr. Candler Mr. Forshay

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

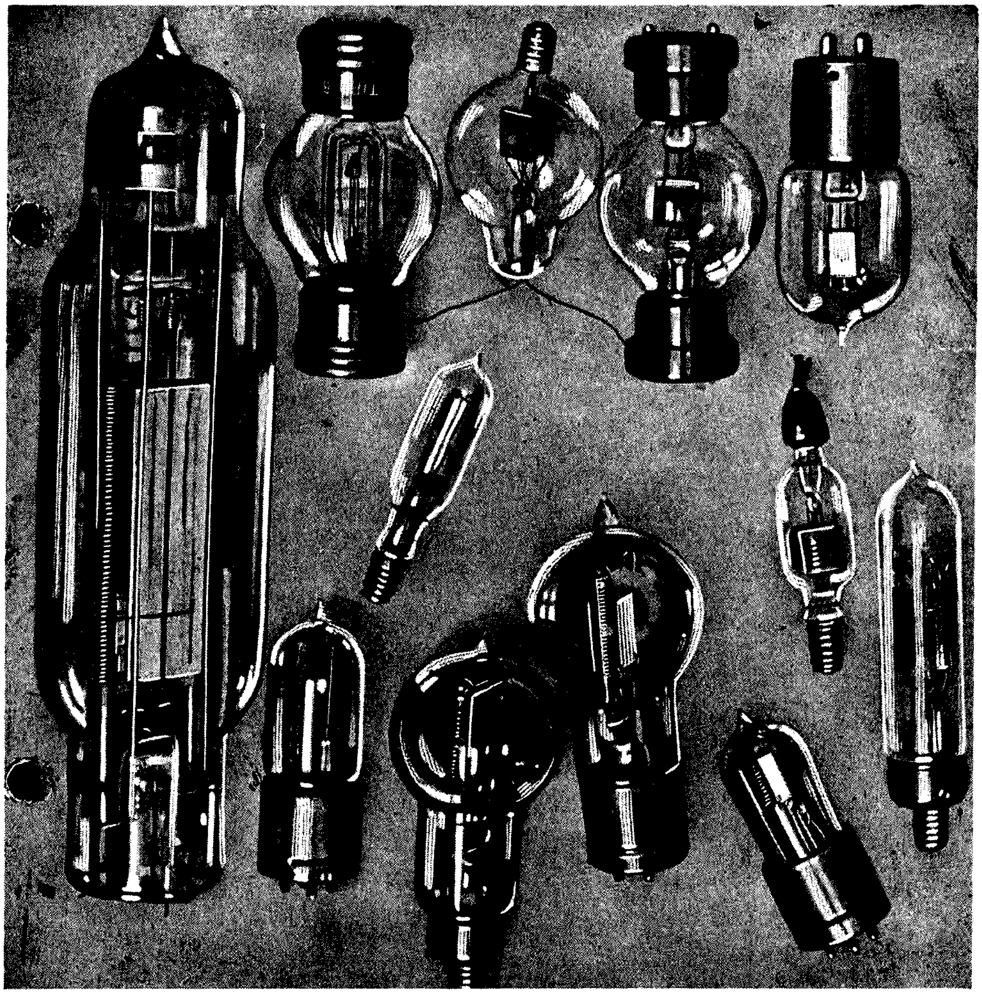
Old Man should any of the sparks of recording effort be transplanted into the pages of amateur history in the future. Probably nothing would surpass the account written in *QST*, February, 1921, pages 9 to 23.

For now, my notebook contains the following account of The American Radio Relay League Convention, as originally written and recorded in January, 1921:

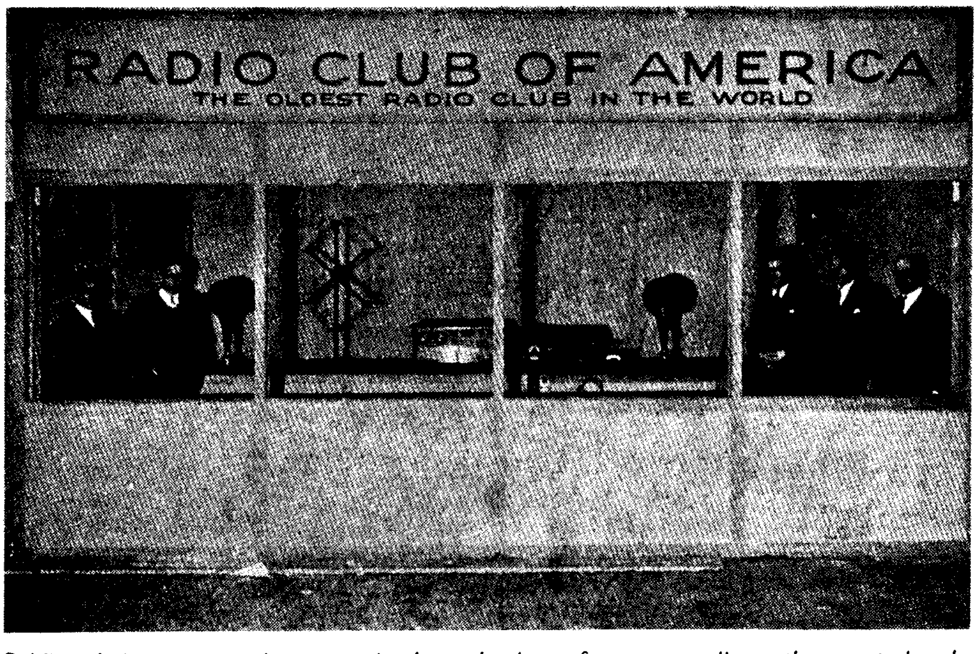
"The Midwest Division of the American Radio Relay League held its convention in St. Louis MO, December 28, 29, and 30, 1920. Representatives from all sections of the country were there, including all of the nine radio districts in the country. Never before in the history of the League has such a successful meeting in the interest of radio taken place. For three days, old and young met, in most cases for the first time, although they had known each other for years.

"Hiram Percy Maxim, well-known scientist and inventor, and President of the League, opened the convention with an address. Mr. Stewart, our representative in Washington, outlined the legislative situation, pointing out how the Poindexter Bill recently introduced in Congress is threatening the existence of amateur radio operators and experimenters. A committee was appointed to draw up definite resolutions to be sent to Washington protesting against the passage of the bill. Mr. Warner, Secretary and Editor of *QST*, gave a resume' of our growth from its inception only a few years prior to the war up to the present time. He stated that membership of over 50,000 has placed the organization in a position where it ranks as one of the largest in the country.

"The technical meeting was held on the 29th. Among the speakers were Mr. B. West 8AEZ, naval radio aide and authority on spark dischargers; Mr. Paul R. Godley, chief designing engineer for



A selection of early vacuum tubes — a far cry from the ultra-miniature transistors and ICs of today.



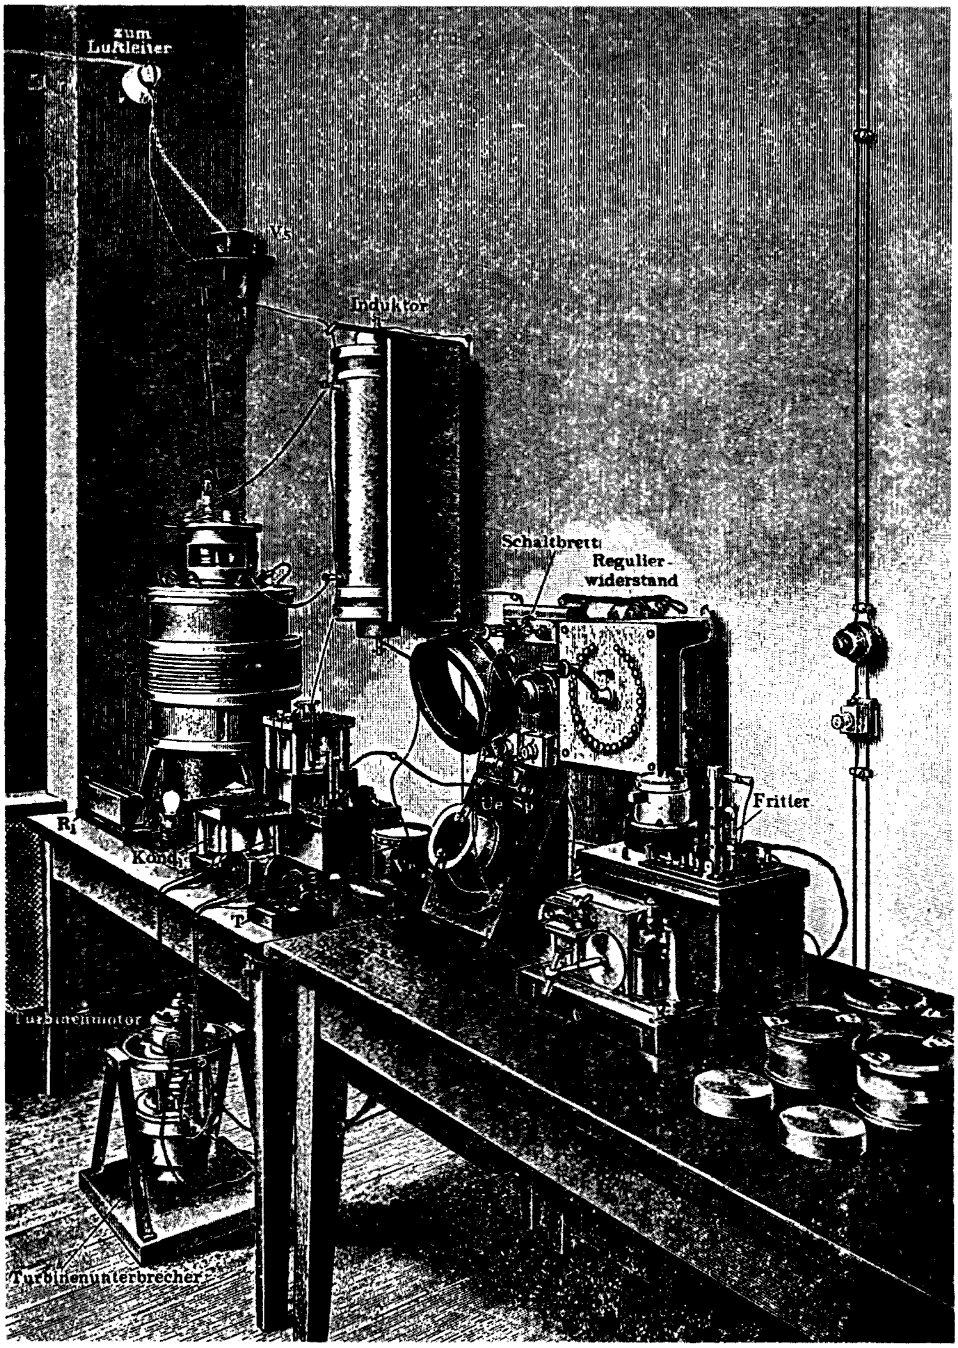
Public relations were as important in the early days of amateur radio as they are today. In 1922, a group from the Radio Club of America set up and manned this booth at a radio show in Grand Central Palace in New York City.

the Radio Corporation of America; and Mr. R. H. G. Mathews, ninth district superintendent of the League. Topics discussed were in connection with apparatus used in amateur radio stations. Since all amateur stations in the country are restricted by law to operate on a wavelength not exceeding two hundred meters and an input not exceeding one kilowatt, it is essential that all energy put into a set be used to best advantage. The maximum efficiency can be obtained only when apparatus is designed accuately and with special attention to details. The realm of radio is still wide open to improvements with new discoveries continually being made.

"Perhaps of greatest interest was the short but spellbinding address given by Mr. Haddaway, a young man seventeen years old. This lad came from a poor family. As a high school freshman, he had to use his spare time to support the family. He gave us a description of how he made the 'moonshine bulb.' Despite various handicaps, he had built a complete and effective amateur radio station, located in a tiny closet in back of his mother's kitchen. How did he go about accomplishing an 'impossible feat'? Every piece of equipment, including the individual components, were meticulously fabricated out of anything and everything imaginable. Even the headphones and tiny vacuum tubes were homemade. He had located a wholesale drug firm discarding waste material and there found scraps of glass tubing, and bits of tungsten filaments from old lamps. With such parts, he made his vacuum tubes. He had built his own mercury pump to evacuate the tubes. He found the mercury from broken thermometers. His headphones were ingeniously fabricated from bits of wood, metal, and wire, but they performed beautifully. Everything else in his station, which was visited during the day, was very cleverly made and assembled. And his only financial expenditure was a 25 cent pair of combination pliers. I have met no one in my lifetime who has displayed such a passionate purpose to succeed.

"The climax of the convention was the radio banquet. To our knowledge, it was the first of its kind ever given in the history of the League. The spirit was there all right! What the St. Louis radio club did not think of was not worth considering. Even the menu savored of sparks and ozone, none of it, however, being charged to very high voltage. Mr. Chandler of 8NG fame, Mr. B. West, and the President, H. P. Maxim, gave short addresses. Bill Wood of St. Louis club acted as toastmaster. To him as well as to the entire club is due the credit for the overwhelming success of the convention.

"The keynote of the meetings seemed to be *More Unity and More Cooperation* between the various clubs and organization as a whole, in



The "ideal" amateur station in 1920, consisting of one transmitter and two receivers. One receiver uses an electrolytic detector and telephone set. The transmitter utilizes a mercury interrupter and an open core transformer.

order to be able to stand behind any move which the League attempts to undertake. Every city in the country should have an organized radio club affiliated with the League.

"The ARRL was organized with the intention of relaying messages from city to city, state to state, and ultimately from country to country. Messages accepted for transmission are not charged for. Amateur radio operators do this as a service for the community and for mutual benefit because they have an interest in the development of radio as a ready means of communication. The stations are privately owned and operated, in many cases entailing an expenditure of hundreds of dollars. To be able to communicate with others hundreds of miles away amply compensates the amateur for erecting a station. It affords one of the most fascinating and at the same time educational fields of research to most any person interested in science.

"Radio is indispensable in many of our present day developments. Steamships and airplanes are lost if they have to do without the services of wireless. On railroad trains and automobiles, its application will eventually revolutionize modern business practices, just as the telegraph and the telephone have done. But to attempt to make far-reaching predictions, not even the most farsighted radio engineer can come anywhere within the actual facts which will be known ten years from now. (Remember that this was written in 1921.) Too little is understood of this greatest of all discoveries. That we will be able to talk directly with our friend riding in his car in another part of the country seems to be a dream still to be realized." (End of 1921 written and recorded message.)

To be continued.

The Oily Resistor Wattmeter

-- how to put 20 W into a I W resistor

George Hovorka WA1PDY
John Hovorka, Jr.
674 Brush Hill Road
Milton MA 02186

Often after an FM rig becomes a few years old, it is desirable to retweak the final output stage. But if you don't have a dummy load and an inline wattmeter, this job can be a problem. Here is a simple device to tune up your two meter transceiver for maximum power output. It is both a dummy load and an rf indicator, and can be built for less than a dollar. It can be used for FM rigs up and into the 20 Watt output class.

The usual problem with constructing a dummy load is finding a resistor which will handle enough Watts and also remain relatively nonreactive at 146 MHz. In our design, this problem is solved by using a 50 Ohm, one Watt composition resistor, and immersing it in a small jar of oil. We can run 18 Watts into this setup for a few minutes without the oil even getting warm. I have used this method successfully to tune up my Regency HR2B and my TR-22. The diode and the capacitor serve as an rf indicator.

This device is constructed by wiring the diode, capacitor, and resistor together as shown in the wiring diagram. Then this assembly is wired to the leads of a piece of RG-58 coaxial cable. Run a separate piece of hookup wire out from the diode and then punch a hole in the top of a baby food jar. Slip the assembly through, and seal the hole with epoxy. Then fill the jar with a high viscosity motor oil, such as SAE 30 or 40. Close the jar top tightly. Then connect a PL-259 connector to the end of the piece of coaxial cable.

To use your dummy load-rf indicator, connect the PL-259 to the back of the radio. Put your VOM on the plus 10 volt dc scale, and connect the positive lead of the VOM to the wire which runs out from the diode. Connect the negative line from the VOM to the braid of the coaxial cable or to the chassis of the radio. Place the transmitter on a frequency which falls in the middle of the frequencies which are used (146.52 MHz). Tweak the capacitors in the final output stage and driver stages with a plastic alignment tool, until you have the maximum indication on the VOM.

With this setup, you can peak your transmitter for maximum output both simply and inexpensively. ■

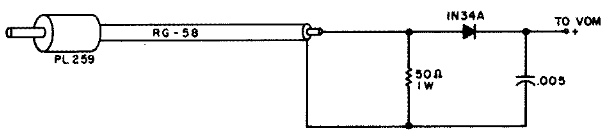


Fig. 1. Wiring diagram.

Parts List
- PL-259 connector
- 18" length of RG-58 coaxial cable
- 1 W 50 Ohm composition resistor
- 1N34A or equivalent germanium small signal diode
- .005 disc ceramic capacitor
- Hookup wire
- Baby food jar
- SAE 30 motor oil
- VOM
- Epoxy

SSTV Slalom Game

-- you don't need a sports car

Dave Ingram K4TWJ
Eastwood Village #604 No.
Rt. 11 Box 499
Birmingham AL 35210

If you've ever been interested in TV ping pong, hockey, space war, or any other popular TV game, then here's an SSTV game I'm sure you'll like. The game features moving action, programmable courses, black or white displays, optional scoring, and much more. The basic unit costs approximately five dollars to build and the optional scoring section costs an additional five dollars.

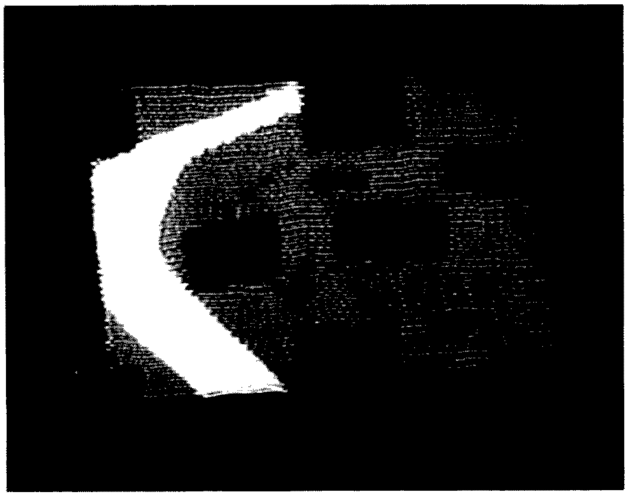
This game is a video representation of the popular sports car autocross, or slalom, races which are conducted by sports car clubs around the world. Contesting autos in a slalom individually maneuver through an obstacle course which is marked by rubber pylons. Tricky courses are commonplace, so driving skills and accuracy are the primary considerations. If you've never experienced an actual sports car slalom, you've missed a treat. Full details on local slaloms can usually be obtained from MG or Triumph dealers in your area. *SSTV Slalom* consists of an obstacle course, displayed on the monitor screen, and a "car" (thin line) which moves down the screen along with the initial trace. A pot is used for steering the line around pylons (black squares), and a simple 1, 2, 4, 8 counter performs optional scoring.

The challenge of slalom driving is captured in the game's positive response to steering commands, and in courses which can be made increasingly difficult as you become more skillful. During a typical "run," the car might be steered left and driven through a pylon. As it's steered back on course, it continues to move down screen, and is again meeting a turn and dodging pylons. A run is completed at the screen's bottom right, and bam! The car restarts at the screen's top left, again dodging pylons to get on course. Each run lasts approximately 8 seconds – the length of an SSTV frame.

Description

SSTV Slalom can be divided into three categories: the course, the car, and the optional accessories.

As this is intended to be a fun project rather than a soldering experience, I chose to utilize one's existing SSTV camera (or tape recorded SSTV) to generate all the necessary timing signals and to permit frequent course changes. This approach (known by computer freaks as letting software make up for a deficiency in hardware) proved to be more flexible and substantially less expensive then other methods of generating TV games. Each slalom course is drawn on a separate piece of paper and sequentially placed in front of the SSTV camera. A forty or fifty Watt lamp will provide sufficient illumination if the courses are placed on small index cards. An alternate method is to draw the courses on photographic slide blanks, then place these in an inexpensive slide viewer and



Six second exposure of a Slalom run. Although not apparent in this photo, the complete course was visible on the monitor screen.

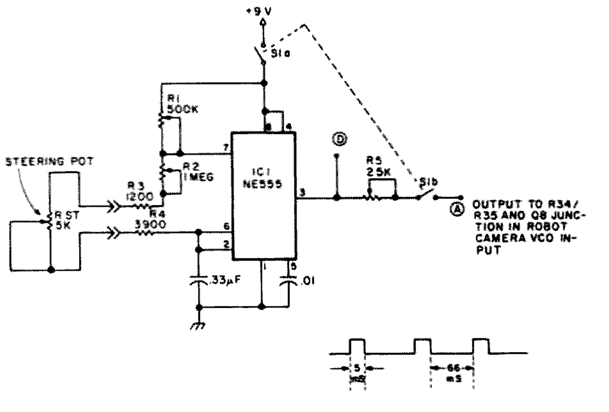


Fig. 1. Basic car generator. R1 – car frequency; R2 – car width; RSt – car steering; R5 – output amplitude.

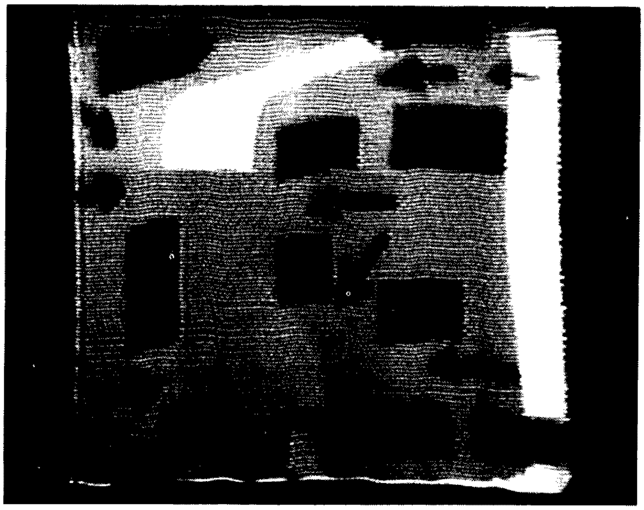
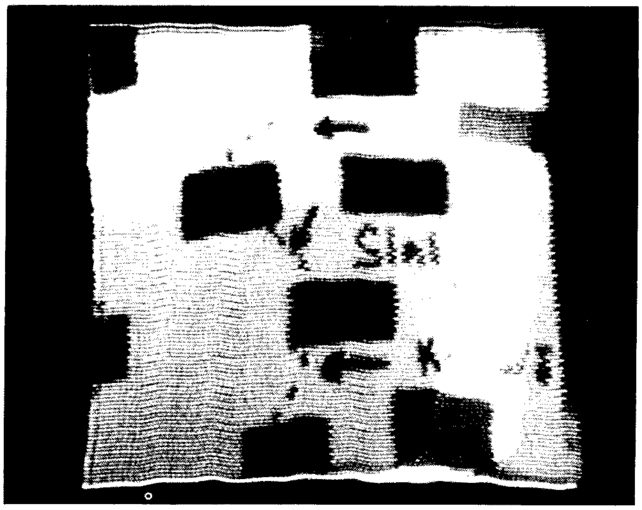


This ten second "stop motion" photo of Slalom closely resembles an actual run in progress. During the first 8 seconds, the car was steered down the screen's right side. Then it was quickly steered on course before the camera's shutter closed 2 seconds later. I'll let you guess the run's results.

Capturing Slalom's action on film is quite difficult, as each run tends to erase the previous run and an 8 second frame doesn't portray motion. Proper "f" settings of double exposure photos are also difficult.



Another ten second "stop motion" photo of Slalom.

point the SSTV camera's lens into the viewer. Particular attention should be given to the beginning (screen top) and end (screen bottom) of each course for a smooth overall effect. I suggest trying some initial courses with various size obstacles and paths to get the game's "feel." The only remaining requirement is a car which can be driven through the monitor displayed course.

The car is simply an unsynced black (or white) level generator with its exact frequency controlled by a steering pot (see Fig. 1). Span limiting resistors are used with the steering pot to control car swing and produce a sports car type "feel." (No fair replacing this section with a 10k pot. A bug eyed Sprite or Lotus Elan doesn't even handle that good!) Output of the basic generator connects to an SSTV camera's voltage controlled oscillator input to combine car and course. Since I use a Robot model 80A camera, Fig. 1 gives the proper connection points for that unit. A similar concept can be used with other SSTV cameras. Simply connect the car generator's output (point A) to the camera's VCO input, in parallel with modulation voltages from the video amplifiers. Isolate levels as necessary to prevent overloads or low resistance paths. Direct connection of the car generator to the Robot's VCO will require a slight readjustment of the brightness control. I merely reach over and turn the control approximately ½ turn clockwise. However, lazy hams can include the circuitry of Fig. 2 and eliminate this effort.

One optional feature of *SSTV Slalom* is a car generator to be used in conjunction with cassette taped courses received from other SSTVers. This method also allows camera-less SSTVers to play *SSTV Slalom* on tape recorded courses. The additional 1500 to 2300 Hz oscillator circuitry for this feature is shown in Fig. 3. Another 555 IC is used as a 1500 Hz (black car) or 2300 Hz (white car) oscillator. Pulses from the basic car generator (point A of Fig. 1) key this oscillator at a 15 Hz rate. Output tones from the oscillator are directly mixed with SSTV from a tape recorder, and applied to the monitor input. A small amount of interference has been noticed while using this setup. However, it can be eliminated by using bandpass filters. I didn't include a filter because the *Slalom* pictures were merely being viewed rather than being transmitted.

Although *Slalom* in its most basic form provides all the fun of full blown TV games, optional scoring may provide an added bonus. This is accomplished by including the circuitry shown in Fig. 4. Two 7476s are wired as a simple 1, 2, 4, 8 counter and a 7400 is used to AND camera and car generator levels. When the camera produces a black level pulse (indicating a pylon), *and* the car generator produces a black level pulse (indicating the car), a binary 1 pulse is applied to the 7476 counter. Some isolation/processing of input levels is desirable, thus sections A, B, and D of the 7400 are wired as inverters. Light emitting diodes are connected between "Q" and ground of each J-K flip-flop to indicate score. These diodes will indicate counts from 0 to 15 (1111, or all four LEDs lit) before resetting, or S1 can be used to reset the counter after each run. This gives the SSTVer two options: He can score each run separately, or let the counter accumulate several runs and divide its total by the number of runs to derive an average score.

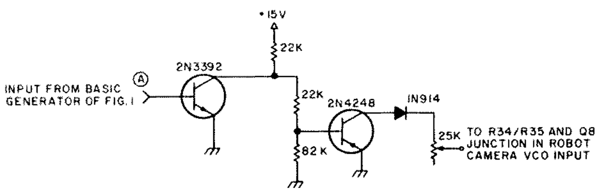


Fig. 2. Optional car/Robot interface.

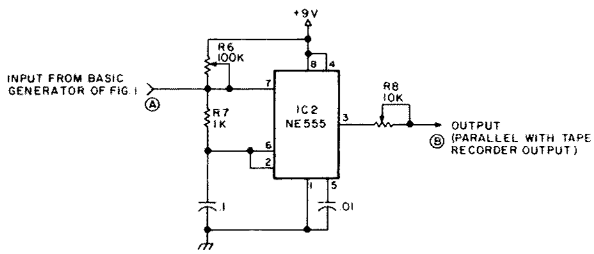

Fig. 3. Optional 1500/2300 Hz oscillator.

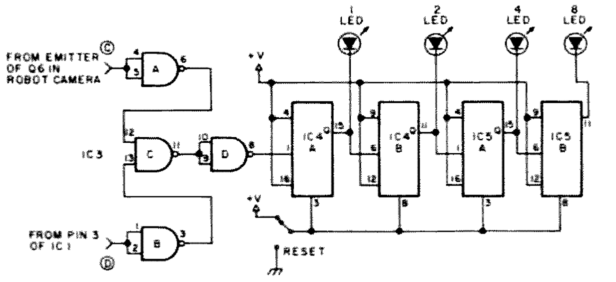

Fig. 4. Optional scoring for Slalom. IC3 – 7400, +V = +5 V. IC4 and IC5 – 7476.

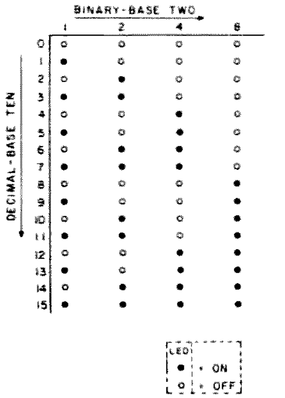
Construction

Because the highest frequency associated with *Slalom* is 2300 Hz, vectorboarding components is quite sufficient. Resistor values shown permit ample variations of frequencies and amplitudes, so there should be no problem getting a properly wired unit working. IC sockets are suggested if surplus 555s are used which may work incorrectly.

The actual game can be built several different ways to suit particular interests, so feel free to "tailor" your design.

I built two versions of *Slalom* and they both worked smoothly after initial alignment. One version consists of a basic "car" generator (Fig. 1) and scoring counter (Fig. 4) mounted on a 3 by 5 inch board. The board is mounted vertically in my Robot camera. Connections for on/off, steering, and paralleling VCO input are output to a small minibox via a Cinch Jones jack mounted on the camera's rear. An eight foot cable permits the minibox to be moved as desired. Of course, the basic unit can be mounted in a cabinet and its output connected to the camera's VCO via a small jack on the camera's rear, if desired. My other version of *Slalom* is a portable unit which uses the circuitry shown in Fig. 1 and Fig. 3. This unit, and some cassette taped courses, allow the game to be played anywhere on an ordinary SSTV monitor. This game generator is built on a 2 by 3 inch vectorboard and mounted in a small minibox. An on/off switch, output jack, and steering pot are mounted on the box front. Scoring is not included in this simple unit.

Fig. 5. LED pattern associated with counter of Fig. 4.



Alignment and Operation

The first step in game alignment requires tuning the car generator for an output of 15 pulses, 5 milliseconds wide, each second. An oscilloscope is helpful in making this adjustment, but it's not mandatory. Clip lead a light emitting diode between pin 3 of IC1 and ground, then adjust R1 until the LED flickers at a slow rate. Next, adjust R2 until the diode's "on" time is considerably less than its "off" time. Now readjust R1 until the LED is flashing almost continuously, and the generator will be very close to calibration. Final "tweaking" can be accomplished while watching the monitor screen.

The basic game is completed by making proper connections to your SSTV camera; place a sketched course in front of the lens and obtain a sharp picture on the monitor. The course should fill the screen precisely, with no overshoot. Switch on the car generator and adjust R5 until a line (the car) is visible on the monitor screen. Don't overadjust R5, or the camera's frequency swing will be excessive. If you have trouble obtaining a line, cap the camera lens and adjust the camera brightness pot. If more than one line is visible, the setting of R1 is too high. If the line is too wide, the setting of R2 is too high. Operations of these controls interact, so stay cool and make adjustments very slowly. A properly adjusted unit will produce one thin line which can be swung to either side of the screen as it moves downward with the initial trace. Uncapping the camera lens should result in both course and car being displayed on the monitor. If everything is properly adjusted, you should be able to maneuver the car through the displayed course.

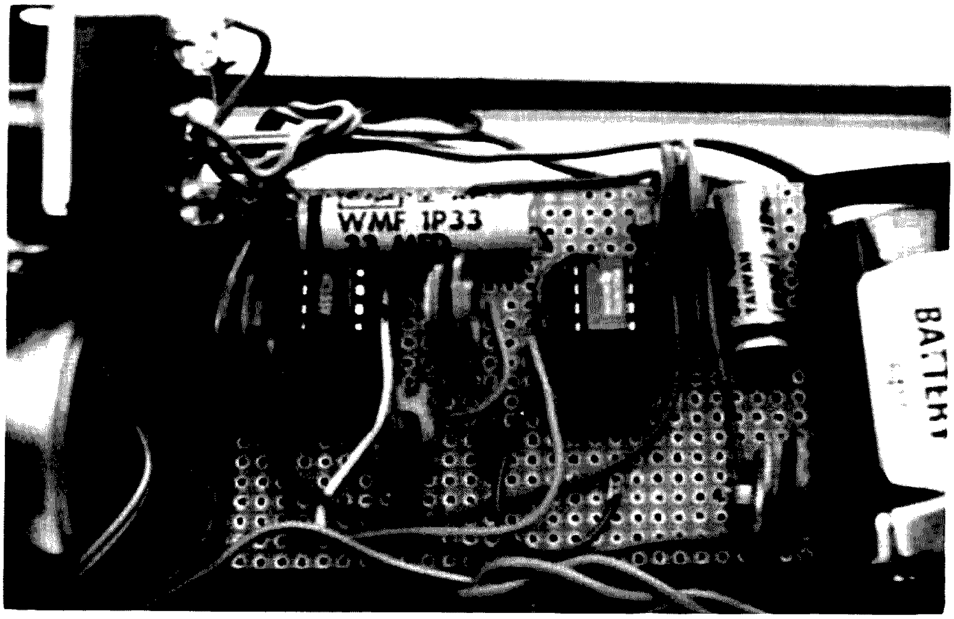
Alignment of the self-contained version of *Slalom* (Fig. 1 connected to Fig. 3) consists of setting the basic car generator using the pre-

This course features two tracks. Runs are alternated between the solid-lined track and the dotted-lined track. When the car finishes at the left bottom and reappears at the left top, it's turning left and must make a sharp right turn. This course keeps you hopping.

A Slalom course as displayed on the monitor screen, with the car generator switched off.

viously described LED technique, then adjusting R6 until IC2 operates at 1500 Hz (black car) or 2300 Hz (white car). IC2 should be adjusted with IC1 unplugged and a small speaker or frequency counter connected between point B and ground. Now reinsert IC1 and adjust R5 until clean, sharp pulsed tones are acquired at point B.

Operation of the scoring counter can be checked by applying ≈ 4.5 volts to point C, then pulsing point D with the same ≈ 4.5 volts. Each pulse should increment the counter one time, as illustrated in Fig. 5. Removing ≈ 4.5 volts from point C should disable the counter when point D is pulsed.



Portable Slalom generator consisting of the circuitry in Fig. 1 and Fig. 3. 15 Hz oscillator is toward front (pot and switch), and 2300 Hz oscillator is near rear (battery). A felt pad insulates board wiring from minibox.

Conclusion

Slalom is an inexpensive SSTV game that SSTVers can enjoy singularly, or in groups. Courses can be designed on paper and exchanged over the air or via mail. Video inversion of courses produces some very striking displays of *Slalom*, and 4 second frames can accelerate game action. I think that you too will enjoy building and playing this simple game.

The idea of *Slalom* hit me during a recent siege of poor band conditions. Continual fruitless calling (at the kW level, no less!) finally convinced me to "do my own thing." Sure enough, it worked. Every time I switched on *Slalom*, the band opened. ■

Computer-Controlled Thermometer

- - take OSCAR's temp with a micro

Browsing through the vast *treasure trove* of articles, labeled as back issues of *73 Magazine* in our high school library, a very good article caught my eye. Entitled "How You Can Take Oscar's Temperature," this particular article described OSCAR 7's telemetry information, including formulas to decode the telemetry. After thinking for a bit, a little bug (actually a PROM memory keyer, I think) flew into my ear and said, "Heck, Herro, you could write a computer program for that!" I said, "You're right!" So I did. Thus, this article was born.

A Little Background

For the few (very few, especially if you read this magazine) who may not know, both OSCAR 6 and OSCAR 7 are alive, well, and

broadcasting their onboard Morse code telemetry, transmitting the ship's status to anyone who happens to be listening. So although this article describes the OSCAR 7 telemetry decoding, the same technique can be applied to OSCAR 6 (and future OSCARs) as well. OSCAR 7's telemetry during Mode A (2m/10m) is transmitted on 29.502 MHz. Thus, anyone with a low band receiver (which means most hams and SWLs around) is capable of at least listening to the satellite and copying telemetry.

The telemetry itself consists of a cycle (called a *frame*) of twenty-four numbers divided into a pattern of six *lines*, and divided again into four *channels* to each line. Channels are designated A, B, C, and D. Thus, any specific number could be referred to as "channel 5C," or whatever. Fig. 1 illustrates. Each number represents a different function or status of the ship. Coming from OSCAR, the telemetry might read like this: HI HI 114 127 143 195 218 223 262 . . . Notice the pattern of 1A, 1B, 1C, 1D, 2A, 2B, 2C, . . . The "HI HI" at the beginning merely separates each full frame of numbers – the telemetry transmits continuously.

LINE #	1	2	3	4	5	6
Channel						
A	1—	2—	3—	4—	5—	6—
B	1—	2—	3—	4—	5—	6—
C	1—	2—	3—	4—	5—	6—
D	1—	2—	3—	4—	5—	6—

Fig. 1. Telemetry channels.

The Program

Although the program is written in BASIC for a DEC PDP/11-45 (the only system I have access to – heck of a toy!!), I tried to keep the program straightforward enough to adapt to any of the other forms of BASIC floating around. It shouldn't take that much memory either. See Fig. 2 for listing.

A little explanation of the program seems to be in order. First of all, the "Date of Copy" and "Orbit #" inputs (lines 30 and 40) are for the operator's information and convenience only. I included them to keep the reception and orbital data straight for future reference, especially if the output is to a TTY or other hard copy device.

Another possible confusing feature is the request to delete the first number of each channel (line 80). The first digit in each channel – the line number (i.e., *1*23 . . . *2*15 . . . *3*67 . . . etc.) – is for reference only and is not involved in any calculation! So if you use the program as is, you would type "23, 41, 77 . . ." instead of "123, 141, 177 . . ." It's possible, of course, to delete that first number within the program, but for the sake of simplicity (and less hassle for the programmer, not to mention memory!), I chose to do it this way. Fig. 3 shows a sample run to illustrate the program operation (I used a "1" as the input in each case).

Since some of the formulas use the same math equation, instead of just retyping that same thing over and over again while putting in the program, I just stuck in the GOSUB statements for lines 9000 and 9500. Let the computer do the work. This is first demonstrated with the "+X Quadrant Current" statement. There are two separate formulas used repeatedly. The answers to *all* the equations will be in the units specified in the preceding PRINT statement. The usual abbreviations apply: milliamp = mA, milliwatt = mW, temperature in Celcius (later in the program, just "Cel"), etc. If you still don't quite understand the program operation, see the flowchart in Fig. 4 for help.

Bells and Whistles

Once you have the bloody thing running, it's kind of fun to see for yourself how OSCAR is doing up there. And, of course, you don't have to stop where the program ends; there are a number of possible modifications. Subtracting out the first number of the channel by the program is one thing, as I said earlier. Or you could try to just calculate one number out

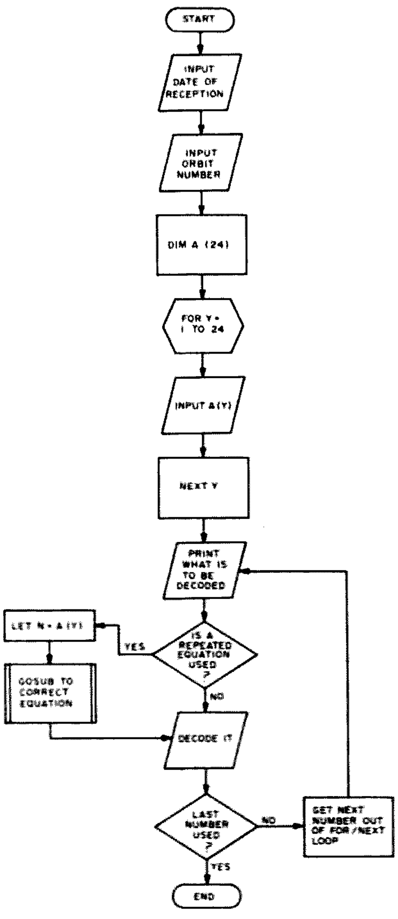

Fig. 4. Program flowchart.

of a whole frame. If you really wanted to go all out, you could try getting your system to take the telemetry Morse code off the air (adjusting for the Doppler shift), decode the information, and print it out at the same time!!

Conclusion

With a minimum of time and effort, it wouldn't be hard to "take OSCAR's temperature" the easy way. If you have a hard copy printout, all the better. You might even try taking a long-term survey of the satellite's performance by saving the information you collect for a time, then graphing the data with your new graphics system! Don't forget AMSAT; I'm sure they would be interested, too.

Now, after you have all that set up, try checking into OSCAR 9's telemetry. That'll have 128 channels when it is launched. ■

Completed RTTY-Computer interface unit.

Computerized RTTY Takeover!

-- Digital Group cassette to TU conversion

A previous article[1] described how to connect a microcomputer to the ST-6 RTTY TU and how to program the computer for RTTY operation. Since all those interested in computer generated TTY may not have an ST-6 TU, I looked into the possibility of using The Digital Group Cassette Interface PC card[2] as a RTTY TU. This article presents the results of those efforts.

The Digital Group Cassette Interface PC card is designed for recording data as well as receiving data previously recorded in a microcomputer system. AFSK is used, with the MARK being 2125 Hz and the SPACE being 2975 Hz. Several circuit modifications were made to the PC board to change it into a low cost RTTY TU. These include shifting the SPACE frequency to 2295 Hz for narrow shift operation and adding two LED tuning indicator circuits to aid tuning in the RTTY signal.

The units as now configured will detect narrow shift RTTY signals, generate narrow shift AFSK signals, provide keyed input for CW ID, and will directly interface with the input/output ports of The Digital Group 8080 microcomputer.

A very detailed circuit description of the cassette interface board is given in the kit assembly instructions and will not be repeated in this article.

Circuit Board Modifications

In order to find space to install the LED drivers, a portion of one of the voltage bus lines was cut and rerouted by adding two jumpers. The cut segment of the line was removed, and holes were drilled in the board to mount the LED driver transistor sockets and resistors as shown in the PC board sketch. External connections from the LED indicators were made to PC board pins 16 and 17. The selected resistors and capacitors required to retune the filters and VCO to the narrow shift frequencies are also noted on the PC board sketch. No other modifications were required to put the PC board into operation.

Construction

The PC board and power supply are mounted in a cabinet 8" wide by 5-3/4" deep by 2" high, a Ten Tec model JW-8. The power transformer selected did not originally have a center tap. The transformer laminations were disassembled and the primary windings were removed and stored temporarily on an empty wire spool. The secondary dc resistance was measured and sufficient turns were unwound until the center tap point (½ the dc resistance of the secondary winding) was reached. The center tap was brought out and the wire rewound on the form. The primary was then rewound on the transformer form, and the part was reassembled with the coil form inverted 180 de-

Fig. 1. System block diagram.

grees to put the terminal lugs as far away from the mounting feet as possible.

A power ON pilot light indicator was made by monitoring the rectified secondary voltage with an LED protected by a current limiting resistor. The output of the VCO is a triangularly shaped wave, and is not suitable for modulating an SSB HF transmitter. An output transformer was installed in the unit and a .1 capacitor was connected across the secondary of this transformer to modify the wave shape into a sine wave. A gain control was added to aid in adjusting the output to a level suitable for the microphone input of the SSB transmitter. When the unit was first constructed, the output transformer was mounted near the power transformer. This caused hum to appear in the output of the AFSK signal, so it was moved up to the front of the unit and out of the strong ac field of that transformer. This

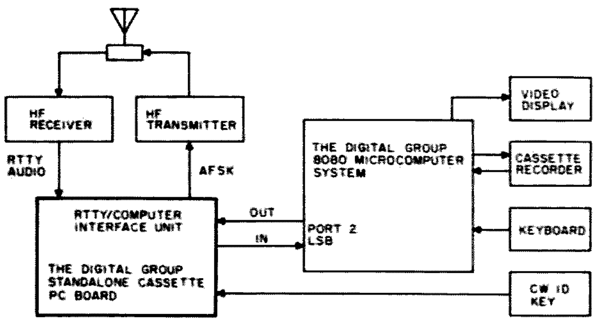

Fig. 2. Schematic diagram of modified Digital Group cassette interface circuit.

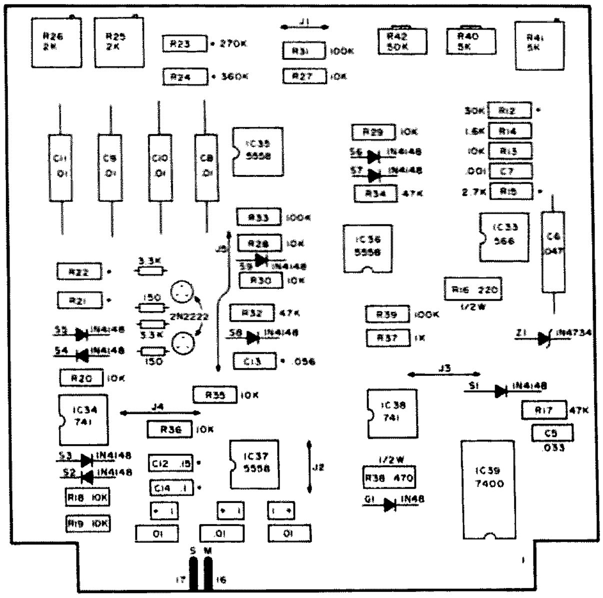

Fig. 3. Modified component layout for Digital Group standalone cassette interface.

cleared up that problem.

Adjustment

The power supply was wired up first, and before the circuit board was plugged into the connector (furnished in the kit), a check of the output voltages for proper voltage and no ripple was made. Some ripple was noted on the -12 volt line after the PC board was inserted. This was eliminated by adding the capacitor across the -12 volt bus as shown in the power supply diagram. The alignment instructions provided by The Digital Group data sheets were followed, except that the audio frequencies used were 2125 and 2295 Hz. The unit tuned up without any complications as per the instruction data. Incidentally, I used an audio frequency synthesizer[3] as a standard signal source. This unit generates the RTTY audio tones accurate to within several tenths of a Hertz. A digital counter[4] was used to monitor the adjustments of the VCO.

Operation

With the RTTY/Computer interface unit connected between the amateur station receiver and transmitter and computer as shown on the block diagram, the HAM-1 tape is loaded into the computer. A RTTY signal (60 speed, narrow shift) is tuned in on the receiver while the two LED indicators on the interface unit are watched. As the receiver is tuned across the RTTY frequency, first one LED will flash, and then both. Then the other will flash on and off. The optimum point is when both are flickering, indicating that both the MARK and SPACE signals are being received properly. A 7-1-1 is keyed on the computer keyboard to tell the computer to set the speed at 60 wpm, receive mode, in upper case letters. The resulting decoded Baudot signals should begin appearing on the video monitor beginning in the upper left-hand corner of the screen.

To transmit the TTY signal, the RESET key is depressed, and when the computer monitor program appears an instant later, the key 8 is depressed. This calls up the computer in the TTY keyboard mode. The transmitter is keyed, and as the keyboard is used, the AFSK signal will be modulating the transmitter in 60 speed, Baudot RTTY.

If the computer is loaded with The Digital Group Tiny BASIC Baudot,[5] the RTTY system is capable of receiving and sending data in the Tiny BASIC format. Listings of games and programs may be sent when the computer is programmed for Tiny BASIC Baudot. Received listings in this format are printed on the TV screen, and if an interface box as described in reference 5 is used in conjunction with this unit, a hard copy can be printed out on the TTY machine. These various modes have been very successfully used here at K7YZZ in receiving and sending both RTTY and computer data on HF to WA7RZW and others.

Conclusions

From on-the-air operation on RTTY and computer data information interchange, it has been noted that as long as you are receiving a strong signal, there is no problem, but when the signal fades, the TU is subject to interference such as CW. The addition of a bandpass filter such as that used in the ST-6 or the DT-600 would help in that situation. Of course, on data transmission you cannot afford an error, so the signal must be very strong with *no fades*. Under those conditions, a bandpass filter is not really required. ■

NEW

Motorola, Motorcycle Radio — Model T33BAT $39.95 FOB Phoenix

Motorola MC14410CP CMOS tone Generator uses 1 MHz Crystal to produce standard dual frequency telephone dialing signal. Directly compatible with our 12 key Chomeric pads. Kit includes the following.
1 MC14410CP
1 1 MHz Crystal
1 Printed Circuit Board (From Ham Radio Sept. 1975)
And all other parts for assembly. $15.70

Fairchild 95H90DC Prescaler divide by 10 to 350 MHz. Will take any 35 MHz Counter to 350 MHz. Kit includes the following.
1 95H90DC
1 2N5179
2 UG-88/u BNC's
1 Printed Circuit Board
And all other parts for assembly.
$29.95

Fairchild 11C90DC Prescaler divide by 10 to 650 MHz. Will take any 65 MHz Counter to 650 MHz or with a 82S90 it will divide by 10/100 to 650 MHz. This will take a 6.5 MHz counter to 650 MHz. Kit includes the following.
1 11C90DC
1 2N5179
2 UG-88/U
1 MC7805CP
1 Bridge
1 Printed Circuit Board and all other parts for assembly.
82S90 add $5.70 to total.
$59.95

10.7 MHz Ceramic Filter
MuRata SFW10.7MA $3.95

Johanson and Johnson Trimmer Capacitors

1 to 14 pf.	$1.95
1 to 20 pf.	$1.95

Let BASIC Control Your Next Contest!

- - with Extended Tiny BASIC language

Dick Whipple
305 Clemson Dr.
Tyler TX 75703

In the November, 1976, issue of *73 Magazine*, we described a simple BASIC operating system for use with Baudot teletypes. Although TBX (Tiny BASIC Extended) was satisfactory for beginning programmers, it lacked several features that could be useful for amateur radio applications. Since the November article, we have modified and expanded TBX to include some of these features. The present article describes this new version of TBX which we call TBX-A (Tiny BASIC Extended-Amateur Version).

String Handling Capability

One of the first additions to TBX was string capability. Message handling, logging, and contest operation all require some form of string storage and manipulation. In its original form, TBX only permitted integer variables. TBX-A recognizes both integer and string variables. As with most other BASICs, string variables are distinguished from numeric variables by affixing a dollar sign to the name. For example: A – numeric variable name; A$ – string variable name. Further, TBX-A requires that strings be stored in dimensioned arrays with two characters per array position. Consider the following example:

```
10 DIM A(20)
20 LET A$(1)="CQ CQ CQ DE W5CUD"
30 END
```

After executing the program, the message "CQ CQ CQ DE W5CUD" would be stored in the A array beginning at position 1. Fig. 1 shows the arrangement of characters within the array. A PR (PRINT) command could then be used to output the stored message to the printer (underline indicates operator input). Example:

```
(Direct command mode)
: PR A$(1) CR
CQ CQ CQ DE W5CUD
: . . .
```

The array argument can be changed to alter the beginning of the string. Suppose you only wanted to output the callsign. The PR command above could be modified with the following result:

```
: PR A$(7) CR
W5CUD
:
```

Printing begins at the seventh character pair and continues to the end of the string. In addition, the array positions not used by the original string can be used for other strings or numeric values. Example:

```
: LET A(15) = 1920
: LET A$(16) = "HRS"
: PR A(15)-20;A$(16)
1900 HRS
: . . .
```

TBX and TBX-A permit the use of two-dimensional arrays. In the case of strings, the second array argument can be used to create separate data blocks with the same variable name. The program shown in Fig. 2 illustrates this technique applied to the creation of logging entries.

The index variable I, used as the second array argument, creates up to ten different log entries. The first argument is used to set up data items for each log entry. The data items, or fields, as they are called, are reserved as shown in Fig. 3.

Fig. 4 further illustrates the two-dimensional storage technique.

When the strings are stored as array elements, they can be further manipulated under program control. In the station log example of Fig. 4, you might want to reorder the file by call area. TBX-A has a string function LEFT(string,n) that creates a temporary string consisting of the leftmost n characters of the given string. By using the LEFT function, the program in Fig. 5 rearranges the log

Fig. 1. A diagram showing the storage of a message as a string in array A.

```
10 DIM A(10,10)
15 FOR I = 1 to 10
20 IN A$(1,I),A(5,I),A$(6,I)
30 NXT I
40. . .
. . . .
: RUN CR
?W2XYZ CR ?1620 CR ?7425KHz CR
?W5UUV CR ?1635 CR ?7430KHz CR
. . . .
```

Fig. 2. Two-dimensional array example.

#	Item	Array Positions
1	Callsign	1 to 4 (Max. 8 char.)
2	Time (GMT)	5 (1 integer value)
3	Frequency	6 to 10 (Max. 10 char.)

Fig. 3. Data items placement within array.

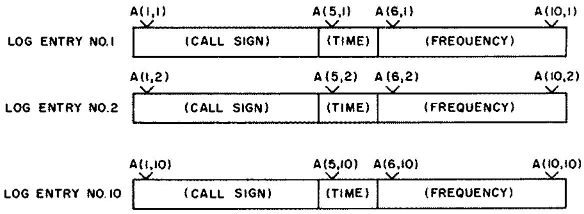

Fig. 4. This diagram shows how two-dimensional arrays can be used to store station log entries. A 10 by 10 array is used to store 10 blocks each, consisting of callsign, time, and frequency values.

file by call area and prints out the result.

Note that the LEFT function is used to extract the leftmost two characters of the callsign, which is the call area. Fig. 6 is a sample run of this program showing the data files before and after reordering.

Ways to Output Strings

Once stored, character strings can then be output to various devices as needed. Output to the local printer is accomplished by the PR statement as in the example program of Fig. 6. TBX-A has two other output modes of special interest in amateur applications:

1. As a RTTY signal to the transmitter; and
2. As a Morse code signal to the transmitter.

Let's consider the RTTY case first. Suppose you have a message such as "CQ CQ CQ DE W5CUD" stored in array A$(1). You are ready to transmit the message over the air as a RTTY signal. On the keyboard, you would type the following command:

:XMT(A$(1),100) CR

The XMT command in TBX-A has two arguments. The first is the string variable to be transmitted, while the second is a number indicating the rate at which transmission is to take place. Thus you are able to send pre-stored text at any desired speed — even faster than your local teletype. The XMT command can appear as part of a program as well as a direct command. For instance, the message above could be sent several times in succession if the XMT command appeared in a FOR-NXT loop. Consider the short program below:

```
10 DIM A(20)
20 LET A$(1) = "CQ CQ CQ DE W5CUD"
30 FOR I = 1 to 3
40 XMT(A$(1),100)
50 NXT I
60 END
```

After entering the RUN mode, the message would be transmitted three times, one after the other.

To transmit a string via Morse code involves the use of the SM command. It is very similar to the XMT except that the characters of the string are output in Morse code to a single bit (on-off) output port. The appropriately interfaced port in turn keys the transmitter. Thus, it is possible to automatically send a coded message. The example program below illustrates the use of the SM command:

```
10 DIM A$(20)
20 LET A$(1) = "WA5NBQ DE W5CUD"
30 FOR I = 1 to 2
40 SM(A$(1))54)
50 NXT I
60 SM(" K ",54)
70 END
```

As with XMT, the first argument of the SM command is the string to be sent, and the second is a speed constant. The program above might be used at the beginning and end of RTTY transmission.

Corresponding to the transmitting commands outlined above are two commands that permit you to use the local keyboard as the source of data instead of stored strings. Let's again take the two commands separately. To enter the RTTY mode, you use the following command:

:XMD(100) CR

At this point, the local keyboard will act as the data source for the RTTY transmission. Each keystroke will result in that Baudot character being transmitted at a speed determined by the single argument of the XMD command. To exit the XMD mode (bringing the local keyboard back to the TBX-A command level), one enters two FGS in succession. Note that the transmitted speed is not limited to the local machine. It can be made faster or slower by simply changing the speed constant.

The second direct transmitting command allows the local keyboard to generate a Morse code signal. In our original version of TBX-A, a keystroke would immediately cause the corresponding Morse code for that character to be sent. We found this to have several undesirable effects. The code generated was not sufficiently regular in

```
10    DIM A(10,10), T(10)
. . .
100   LET C = 0
110   FOR I = 2 to 10
120   IF LEFT(A$(1,I-1),2) < LEFT(A$(1,I),2)GOTO 230
130   LET C = 1
140   LET T$(1) = A$(1,I)
150   LET A$(1,I) = A$(1,I-1)
160   LET A$(1,I-1) = T$(1)
170   LET T(5) = A(5,I)
180   LET A(5,I) = A(5,I-1)
190   LET A(5,I-1) = T(5)
200   LET T$(6) = A$(6,I)
210   LET A$(6,I) = A$(6,I-1)
220   LET A$(6,I-1) = T$(6)
230   NXT I
240   IF C = 1 GOTO 100
250   FOR I = 1 to 10
260   PR A$(1,I);A(5,I);A$(6,I)
270   NXT I
280   END
```

Fig. 5. Program for rearranging the log file by call area and printing the results.

	BEFORE	
W2XYZ	1620	7425 kHz
W5UUV	1635	7430 kHz
W1AAC	1810	7420 kHz
W1QRX	1912	7420 kHz
	AFTER	
W1AAC	1810	7420 kHz
W1QRX	1912	7420 kHz
W2XYZ	1620	7425 kHz
W5UUV	1635	7430 kHz

Fig. 6. The two listings show a group of station log entries as first entered and then as rearranged by call area with the sorting program given in the text.

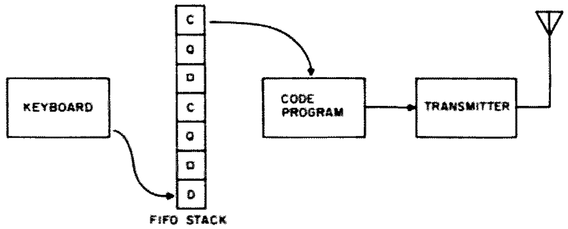

Fig. 7. This diagram indicates the flow of data from the keyboard to the transmitter during direct Morse code operation. The FIFO stack is constantly expanding and shrinking to compensate for different keyboard and code generation speeds.

inter-character spacing, which resulted in copying difficulties. In addition, it caused the operator to type at the code speed (or less), which created a certain awkwardness, especially for people with regular typing rhythms. We then decided that the typing and Morse code generation should be handled independently by the software so that the typist could work at his own speed while the Morse code was being sent with standard character and word spacing. What was needed was a FIFO stack (First In First Out). To illustrate the technique, see Fig. 7. As the keyboard is struck, the Baudot character is placed on the bottom of the stack (actually a group of 72 consecutive memory locations). Each new keystroke "pushes" that Baudot character onto the stack from the *bottom*. The Morse code generation program "pops" or takes the characters from the *top* of the stack and sends the appropriate code to the transmitter. Here is the really important point: the *pushing* and *popping* operations are completely independent and take place at rates determined by the typist and speed constant of the SMD command, respectively. Thus the code produced has an evenness and readability far improved over our original method. Two additional points:

1. When the stack is exhausted (keyboard entry stopped), Morse code transmission also stops; and
2. The buffering action of the stack will only permit the typist to get 72 characters ahead of the Morse generator.

The latter has not been a problem for us, but an overenthusiastic typist could fill the stack. By the way, exiting the SMD mode is accomplished by simply typing a BLANK.

Special Receiving Capability

TBX-A has a couple of receiving modes for RTTY. The first is the RCV mode which is entered using the following command:

```
:RCV(A$(1),100) CR
```

The string variable, A$, will receive and store the incoming RTTY message for later printout. The second argument is once again a speed constant. This mode is useful for receiving RTTY at speeds above that of the local teleprinter. We have not found this to be a very satisfactory approach, since the printout is necessarily delayed. Although not yet implemented, we have given some thought to setting up a FIFO stack as mentioned earlier so that receiving at one speed and simultaneously printing at a slower speed would be possible.

Another RTTY receiving mode uses the RCD command. It has the following form:

```
:RCD(100) CR
```

The receiving speed is determined by the single argument. In this mode the printer is actively copying the incoming signal, which may be at any speed less than or equal to the speed of the local printer. For instance, if the local machine is a Model 28 operating at 100 wpm, RCD will permit direct copy of 60 or 75 wpm signals by using the appropriate speed constant. Exit from this mode is made by typing a BLANK on the local keyboard.

To date, we have not added any Morse receiving software to TBX-A. We have felt that such capability would be of limited usefulness except when receiving machine-generated code.

That about completes our description of TBX-A. Implementing it on your 8080-based system will not be as simple as some of our other programs like BM/E and TBX. For this reason, we are not making a specific offer for a data package as we did previously. We would prefer that those readers who are interested write us at this address: TBX-A Information, Rt 4, Box 52-A, Tyler TX 75703. We will then make an effort to assist by providing the necessary information at a nominal charge (to cover reproduction costs, etc.). ■

BE MY GUEST

visiting views from around the globe

from page 24

You can buy crystals before you go, or, for some of the more popular hand-helds, you can get them in London and have them netted at about the same cost as you pay here. If you will be mostly in London, you won't need many crystals — no two repeaters are permitted within a fifty mile radius! Just get one repeater pair and one simplex. The London repeater is on Channel R7 — 145.175 in, 145.775 out — and it is just frantically busy about 21 hours daily. Since the timer is just 55 seconds, it leads to fast exchanges — and since most users ID themselves and the other guy with each and every exchange, there isn't time for much else to be said! It is tone burst access; if you don't have tone burst, you can get in for 10 seconds. Oh, yes — if your deviation is too low, the repeater will "time out" on you; if you are too low in frequency, you will get an "L"; if too high, an "H". It also sends a "K" at the end of each transmission. Timeouts are very frequent.

You will hear some rather strange sounding signals because much of the equipment is home-built — current state-of-the-art gear already manufactured such as we obtain so readily here is extremely expensive by our standards.

Language barrier? The UK ham will have no difficulty understanding you because he's largely exposed to rebroadcasts of American TV shows. But you might have a few problems understanding his English — especially since he must rush to get in under the 55 second timer! However, his phonetics are the same as yours — Alpha, Bravo, Charlie, etc.

Remember — plan ahead — and be prepared to prove ownership of your equipment when passing through customs. The best way to do this is by registering it before leaving this country with the Customs office. Last but not least: Expect to encounter more than normal interference from other transmissions when operating over there — interfering signals are plentiful by unlicensed stations.

Satellite Zapper

-- effective antenna for weather birds

Ralph E. Taggart WB8DQT
602 S. Jefferson St.
Mason MI 48854

Antennas for reception of polar orbiting weather satellites can be vexing and complicated affairs. Since the satellites generally track in a north-south direction (actually NNE to SSW for daylight passes and SSE to NNW for evening passes) when near overhead, it might seem that a simple dipole oriented east-west might be ideal, since the satellite would always be in the main lobe of the antenna pattern. Unfortunately, the signal from the satellite is linearly polarized and as the satellite changes orientation in respect to the ground station as it passes overhead, the signal polarization as seen at the ground will vary considerably. The solution, of course, is to use circular polarization, resulting in a maximum of 3 dB of signal loss regardless of the polarization of the satellite signal. This is a relatively small price to pay compared to signal losses of up to 20 dB that can occur with polarization mismatch between the ground station antenna and the satellite signal. The two most common antenna types that are useful for satellite service are the helix and the crossed yagi, the latter with its elements properly phased to yield circular polarization. A helix of four or more turns or a 5 element or larger crossed yagi will do an excellent job, but there is one major price that must be paid for the directivity of such antenna arrays – the satellite must be tracked! This generally requires two antenna rotors (one for azimuth and one for elevation) and precludes picture aquisition when the operator is not present. In a past article in *73*, and in the *Weather Satellite Handbook* (available from *73*), I described an automated satellite station that provides a degree of automatic operation so that pictures can be logged without the operator being present. This system is highly effective but is somewhat complex. If the system is set up for logging daylight passes, it is not particularly effective for evening passes and vice versa. Additional programming can be done to permit automatic tracking of daylight and evening passes and the system is useful for obtaining picture data from horizon to horizon.

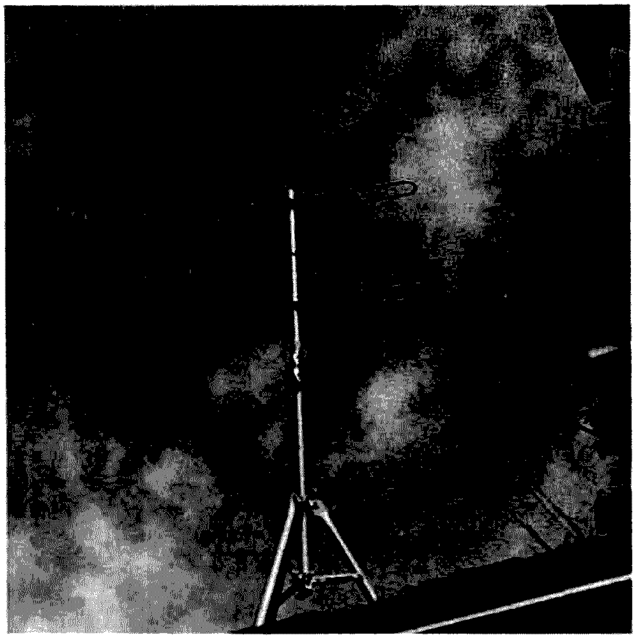

Fig. 1. Photograph of the author's antenna system. The relationship between the phased folded dipole driven elements and the two parasitic reflectors is obvious.

In the process of moving into a new house, I decided to take the opportunity to repackage the satellite station to make it somewhat more attractive and, while wrapped up in that project, I also decided to rethink the antenna situation. Now some of the locals around here will say this is because the house was a magnificent Victorian relic with very steep roof lines and that I was simply chicken to risk my skin crawling about doing antenna work. This, of course, is simply not true – the whimpering sounds that drifted down to the ground during antenna sessions were entirely due to our cat, who is deathly afraid of heights. The fact that the cat was never observed on the roof is immaterial! The real reason, of course, is that I needed room up there for the S band antenna system plus the normal complement of VHF and UHF arrays and simply wanted to see if a simpler approach could be made to work. What we ideally want for polar orbiting satellites is an omnidirectional antenna (with circular polarization) that will yield an acceptable

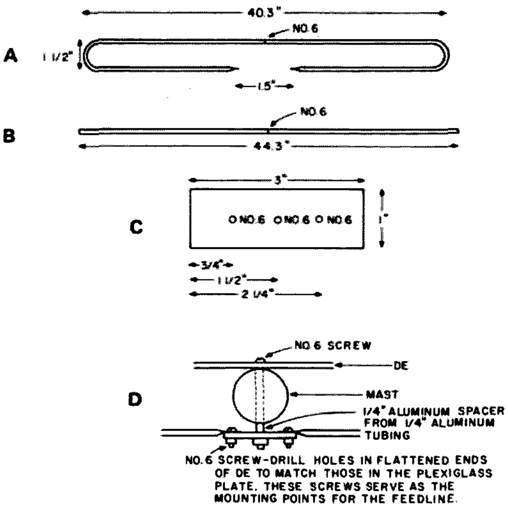

Fig. 2. Antenna element details. (a). Driven element folded dipole fabricated from ¼" aluminum tube. A #6 hole is drilled through the center of the element and 1" of the free ends should be flattened with a 1.5" gap between the ends. Two of these driven elements are required. (b). Details of the reflector element (2 rqd.) of ¼" aluminum tubing. (c). Plexiglas mounting plate (¼" thick) for the free ends of the driven element. (d). Mounting of the driven element to the mast. A #6 screw is placed through the hole in the element, through the mast, and a ¼" spacer is placed over the screw and a nut is attached. Using the holes in the plexiglas plate as a guide, drill matching holes in the flattened end of the elements and secure to the plate with #6 screws.

signal whenever the satellite is more than 5-10° above the horizon. Such an antenna would be ideal for casual operation with the polar orbiters while vastly simplifying the programming required for unattended operations.

The solution came about by listening to the conversations of the folks using the OSCAR satellites. A number of stations were having considerable success using crossed dipoles (properly phased) over plane reflectors for their 2 meter uplink antenna. Such an antenna is not particularly spectacular for receiving downlink signals on two, but I reasoned that part of the difficulty here was that the OSCAR downlink signal is from a translator and the relatively low satellite transmitter output is spread over a considerable bandwidth, thus reducing signal strength from any one station. The 5 Watt transmitters of the NOAA satellites, however, operate at one frequency and thus the signal should be considerably stronger. Since I had all sorts of parts available for the many crossed yagis I have built at one time or another, I decided to see if the crossed dipole idea would work. Most OSCAR operators place the antenna over a plane reflector — usually made out of screen or hardware cloth — and it seemed that the antenna should work equally well with simple reflector elements, thus simplifying design. Part of an evening was spent putting together the antenna illustrated in Fig. 1, and the results have been outstanding. The satellites can be heard whenever they are above the local radio horizon and the signals are full quieting for most of that time. As an example, a daylight or evening overhead pass should permit signal acquisition for a total of about 21 minutes. Such a pass is audible for that entire period on the omni antenna. My own receiver quiets completely at a signal level of between 8-10 microamps on the S meter, and for over 13 minutes of an overhead pass the meter is pinned at 50 microamps! Watching the meter before and after this 50 microamp interval indicates that the antenna has some lobing to the pattern, or less than perfect circular polarization, but these signal variations are minor and the signal will stay full quieting to very near the horizon. If you have a reasonably sensitive receiver and would like a very simple but effective antenna system for satellite work, read on.

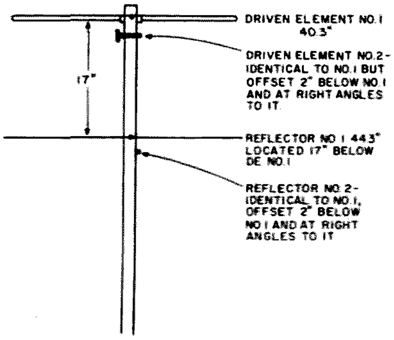

Fig. 3. Relationship of the two driven elements and reflectors. The antenna mast is a 5 foot length of 1¼" aluminum tubing. Driven element #1 is mounted 1" from the top of the mast. Reflector #1 is mounted 17" below it with the same orientation. Driven element #2 is at right angles to DE #1 and reflector #1. Reflector #2 is two inches below R #1 and is oriented parallel to DE #2.

Construction

The antenna elements are fabricated out of ¼ inch aluminum tubing. This tubing size is not critical and even aluminum rod could be used, although the antenna would be considerably heavier. Fig. 2 shows all of the significant dimensions. Support for the two driven elements and the two reflectors is provided by a piece of aluminum TV mast.

Construction begins with the fabrication of the driven elements and reflectors from ¼" aluminum tubing. Bend and drill the two driven elements as shown in Fig. 2. Similarly, cut and drill the two reflectors. Fig. 3 is the guide for preparing the mast. One inch from the top of the mast, drill a #6 hole completely through the mast. Two inches below this hole and at right angles to it, drill another hole. Seventeen inches below the *first* hole,

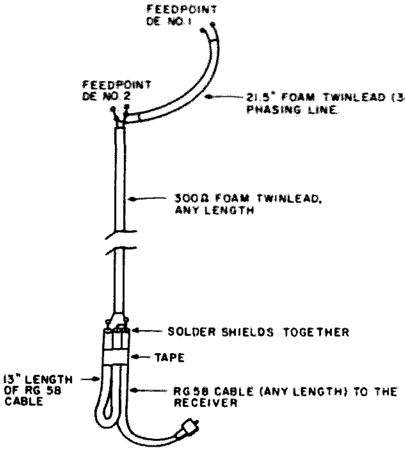

Fig. 4. Details of the phasing line, feedline, and balun.

Fig. 5. NOAA 4 picture readout as received with the omni antenna system and displayed on the author's CRT monitor (the latter is described in the 73 Weather Satellite Handbook*). The portion of the pass photographed extends from Hudson's Bay in the north, south to the central United States. Lake Superior is faintly visible in the lower left of the picture with the lower Great Lakes covered by a massive frontal system that wraps around from the central U.S. up the east coast of the U.S. and southern Canada. Extremely heavy rain was falling as this picture was received, indicating that the antenna performs effectively under adverse weather conditions. The satellite signal remained full quieting until it reached the latitude of central Mexico.*

drill another with the same orientation as the first. Two inches below this hole, drill another at right angles to it (same orientation as hole #2). The driven elements are mounted at the first two holes using Fig. 2(d) as a guide. One reflector is mounted at hole #3 parallel to the unbroken side of DE #1. The second reflector is mounted at the fourth hole, parallel to the unbroken side of DE #2.

Fig. 4 shows the details of the feedline, phasing line, and balun. The feedline and balun are made up from good quality 300 Ohm foam cable. The feedline may be any length and connects to the feedpoint of DE #2 (the lower DE). The 21.5" phasing line has one end connected to the feedpoint of DE #2 with the other end connected to the feedpoint of DE #1 (the upper DE). The feedline should be routed to the shack using good installation practice, i.e., twist the twinlead, use standoffs, and avoid paralleling metal objects such as nearby gutters. The balun is a standard type and should be located right at the receiver. If it is inconvenient to run the 300 Ohm line around the shack, the balun can be used where the line enters the wall or window and the foam cable can be run to the receiver. The 50 Ohm cable should be kept as short as possible, however.

There is no tune-up — simply start using the system. I think you will be very happy with the results. ■

VHF Noise Snooper

- - track down annoying pulses

Are you quite sure that nothing can be done about that noise level at your QTH? Just one of the problems with noise is its frequency content. I had a noise which affected the FM broadcast band and even wiped out 6m, but only contributed 1/2 an S unit on 75m. So I was forced to look for some special device, and found it sitting right in front of me. Here is a new approach to noise tracing, using a piece of equipment you most likely already have.

Simply cut or unsolder one end of either of the FM detector diodes in an AM/FM portable, and you have an ultra portable, ultra sensitive noise detector. A schematic is usually unavailable for these Japanese sets (there oughta be a law!), but you can usually spot the diodes sitting side by side between the last i-f cans and the audio transformers. Shorting one diode will probably work as well, but I didn't try it.

In use, my detector worked amazingly well. First find a blank spot between stations and start out. I tried using a bicycle, but tire noise drowned out the noise I was trying to locate, so I walk now. As you move, the noise will go in and out like airplane flutter, slowing down and getting steady when you are very near. Then you can point the end of the whip at the noise source for a null. One noise was found so accurately that the vertical position on the pole was pinpointed for the power company linemen.

Of course there are other problems. When you rid the neighborhood of all those power leaks, you really notice the cars. ■

Understand Your Pet Rock

-- tips on crystal oscillators

This article explains in basic detail how to construct two crystal tester oscillators, how crystals work, the difference between a "fundamental rock" and an "overtone crystal," why you should have a different circuit for each, and what you should know to start with if you are going to do any serious experimenting and/or building at all using crystal frequency control. This subject demands both *experimental work and basic knowledge of sound waves in "rocks" (crystals). Because of the increasing use, worldwide, of "overtone" crystals (such as, for example, "45 MHz" ones for the two meter band which are actually ground for 15 MHz, as you will find when working with them), it is becoming more and more necessary to have a good circuit and to know how it works.*

There has been for some decades a strong push towards ever-higher frequencies due to the space available there, and this force upwards in frequency must of course accelerate as populations and countries develop further.

The lad who plugs a 146.5 MHz rock into an already working *two meter rig does not necessarily need to read this article, but the amateur-experimenter who intends to build his own and wants to* know *what is going on should read it, because that little piece of quartz may be operating with either three or five half waves of* sound *inside its little tin can. Or maybe even seven!*

The use of quartz crystals for controlling the frequency of your transmitter or receiver, and for calibration, is an absolute necessity today even in the most economical types. Even a tunable receiver for amateur use on, for example, the six meter band, should have at least one crystal position for "calling in" for special emergency or net use. These little slabs of quartz operate on the basis of piezoelectricity, in that they expand and contract physically under the influence of electricity, and also *produce* electricity if made to contract and expand mechanically by external forces. A crystal may also act as an "electrical flywheel" or a weighted resonant spring when set in motion at its mechanical resonance frequency, expanding and contracting by an alternating current and/or voltage. There is an ultrahigh frequency sound traveling back and forth through the quartz material, associated with the contraction and expansion, so that the resonant frequency corresponds to the crystal thickness. At 7 million oscillations per second, for example, the crystal thickness is thus paper thin.

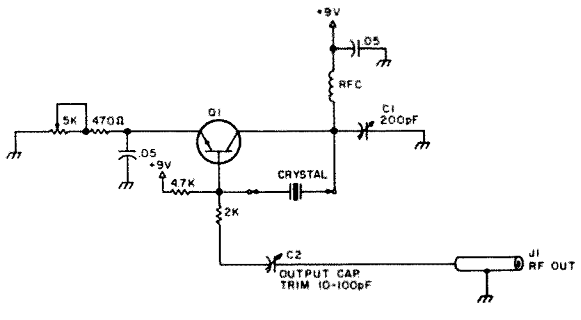

Fig. 1. Untuned crystal oscillator circuit.

When ac (rf) is applied to a 7 MHz crystal, nothing much happens until the frequency reaches 7 MHz. At that time the crystal will oscillate, both mechanically with internal sound waves and electrically with rf waves (these latter rising to several volts if L1 and C1 of Fig. 2 are tuned to 7 MHz). This will tend to hold your transmitter very close to the desired frequency inscribed on the crystal case. Also, if the crystal is used in the local oscillator circuit of your VHF receiver, it will allow your receiver to be tuned to a net or calling in frequency when this crystal is switched in.

Phase Reversal

A little known fact is that

a piezoelectric crystal, generally of quartz for good frequency control, reverses the phase of an rf wave "going through it." Just remember that the Curie brothers, almost one hundred years ago, demonstrated the piezoelectric effect by hitting quartz crystals with a hammer with visible sparks as a result! *Not* recommended at the present price!

At any rate, when the quartz is compressed, positive (+) voltage appears on one side and negative (-) on the other. This feature has a very important and vital usage in the circuits of Figs. 1 and 2.

Fundamental and Overtone Crystals

In order to write this article, I got out my crystal box, which contains over 100 of these little gems representing some 40 years of experimenting with and operating crystal control from 160 meters to X-band (three centimeters).

Going from low frequencies in the HF region around 1.8, 4, and 7 MHz up past about 14 MHz to 18 MHz, crystals change radically in their operation. You will find that from here on up there will be three, five, or even seven half waves of sound inside the quartz material. As I look at the row of crystals I picked out as representative for this article, I find in front of me the following frequencies engraved on their tin or plastic cases; 1.8, 3.9, 6.1, 7.1, 8, 12.5, 14, 18, 21, 26, 28, 29, 45, 50, 60, and 75. Some of these are from before World War II, and some are of the type now sold for as low as 41 cents (U.S.). This latter price, however, only applies when one million are sold at *one time* and on *one* frequency, such as, for example, the color burst frequency near 4 MHz used in TV receivers.

Various "cuts" and types of "optically active" crystals are made which need not concern us here, but we do need to know what kind we should buy and how to use them once acquired. A crystal marked "21 MHz" on the case and plugged into the circuit of Fig. 1 showed plenty of power on 7 MHz, 14, and 21! And quite rightly, too, for this one is ground to 7 MHz and is intended to be used with a tuned circuit of 21 MHz. When on 21 MHz, however, it uses three half waves of "sound" inside, instead of just one. However, do *not* use this for operation on the air with the circuit of Fig. 1, except to learn how it works! To get to *only* 21 MHz output, use the circuit of Fig. 2, which has a tuned circuit on 21 MHz. Going through my crystal samples, another, inscribed 18 MHz, works in both Figs. 1 and 2, because it is cut and ground to 18 MHz and is working on the fundamental. A 14 MHz one does the same, as well as the rest from there on *down* to 1.800. That is, they work in the circuit of Fig. 1. But now let us go higher. A 26.9 job, used in the CB band, shows up right away as being ground for 9 MHz, with power out also on 18 and 27 (roughly). And, continuing upwards and still using the circuit of Fig. 1, just for testing, mind you, and just to show you the principle of multiple half sound waves inside, the next crystal, labeled 30 MHz, shows up with a fundamental of 10 MHz (with power on 20 and 30 as well). Note that the existence of the three half waves (of sound) is due to the extreme thinness of crystals around 15 MHz, and that trying to go further would not be practical. So from there on up we find three, five, or seven half waves inside. The fact that only odd numbers can be used is due to the arrangement of the sound waves inside.

The Circuit of Fig. 1, for Fundamental Crystals

The Fig. 1 circuit is basically an old one souped up for transmitter use. It is quite a reliable one, with the rock between the base and collector of Q1, using the aforementioned phase reversal to maintain correct drive on the base. However, not having any tuned circuit other than the crystal itself, care must be taken with the component values, current and voltages, output coupling, etc., to get good drive out for transmitter use. Even if you are just going to use it for calibration purposes, you need a "good" oscillator for stability, protection against aging of parts, low battery voltages, and the like.

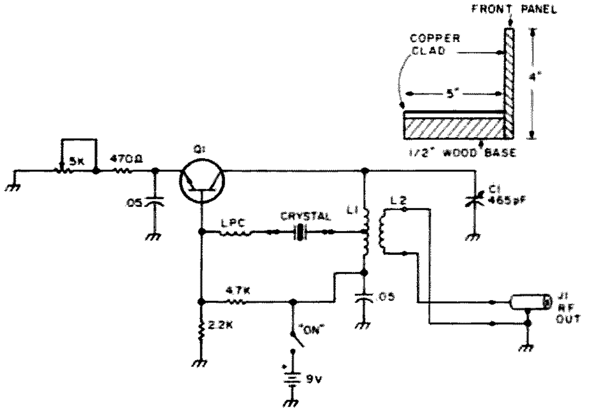

Fig. 2. Tuned crystal oscillator circuit. LPC — phase correction coil (see text). Q1 — see text. C1 — two gang variable, two sections tied. L1 — 6 turns #14 bare copper, ½" o.d., 7/8" long (xtal tap 3 turns from collector end). L2 — 1 turn, semi-adjustable in low end of L1.

Construction

I always use copperclad material for the baseboard, because it is easy to cut, solders easily with a 25 Watt iron, and is an excellent ground. Q1 can be almost any good VHF transistor. The one I used was an SE 3001 by Fairchild, priced at less than P2. The crystal "mount" was a pair of alligator clips, because no less than five different kinds of enclosures, all with different pins (and even one with wires for soldering), were among the crystals I tested (some 16 of them, from 1.8 to 75 MHz). You can, of course, use sockets, if you can find the ones needed for the crystals you have.

The choke can be most anything, but should have plenty of small size wire and plenty of inductance. I used a 16 mm o.d. PVC form 8 cm long, with about 200 turns of coil wire wound single layer. C1 should run up near 450 pF for testing (because power output for different crystals and frequencies is helped), but for an oscillator designed for one band only, a mica compression trimmer will do for C1. You will find it very handy to vary R1 for peaking up the power output and tuning up a good oscillator. The 1k pot is in series with a "safety" R2 of 470 Ohms. Don't forget: Transistors do *not* like to operate without some self-bias in the emitter circuit. The output capacitor, C2, can be a trimmer also, such as a 10 to 100 pF.

After assembling and wiring, check with an ohmmeter for proper values of resistors and possible shorts or opens, and then turn on.

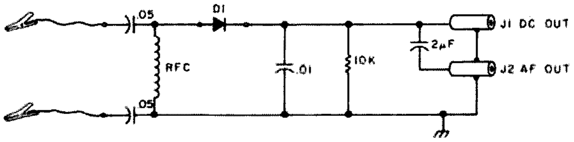

Fig. 3. Untuned diode rf voltmeter.

Using a 7 MHz rock and a 9 volt battery, I found 2 mA of current from the battery with R1 at 3k total and .6 volts rf output into the TD (see Fig. 5 for the tuned diode). A maximum of 2 volts dc from the TD was obtained with an R1 of 1k and 3½ mA of current. Some other crystals gave up to 5 volts or more with everything "peaked." Note that, with only a small value of C2 into the TD, frequency determination is the goal rather than maximum rf voltage indication. In general, for control of a transmitter, do *not* use maximum output. First determine the value of C2 for maximum output, and then *always* operate with *less*. Always run a check on the *minimum* dc voltage with which the crystal will oscillate. This should be *several* times less than the operating voltage.

After checking my fundamental crystals (which all worked well and gave good output in the Fig. 1 circuit), I went up through the 12.5, 14, and 18.3 MHz ones until I hit the one labeled 21.3 MHz. This one immediately showed strong power out on 7, 14, and 21 MHz, indicating that it was an overtone unit. Putting it into the circuit of Fig. 2 resulted in an output of 21 MHz only, the frequency for which is was designed, with the internal presence of those three half sound waves.

Note that output coupling in Fig. 1 is obtained from the low impedance side of the crystal, that is, the base side of Q1. Of course, you can use an emitter follower if you want to be fussy.

Again, remember that the Fig. 1 circuit is for fundamental crystals only, and not for overtones (except to increase your basic knowledge).

The Circuit of Fig. 2, for Overtone Crystals

The same type of copper-clad baseboard and arrangement as in Fig. 1 can be used, with only slight changes in the schematic – but these are quite vital. The use of tuned circuit L1, and the tapping down of the crystal on L1, results in operation on the inscribed frequency, provided, of course, that L1 and C1 are tuned to that frequency.

Operation is as follows. Q1 acts as an amplifier with 50 MHz (assuming you have plugged in the 50 MHz crystal) energy from L1 and C1 feeding back through the crystal to the base, where the desired 50 MHz energy is again amplified by A1, again appearing in amplified quantity on L1, etc., etc. This of course constitutes an oscillator, and a very stable one at that, compared to a non-crystal controlled one. The 50 MHz energy predominates in the output when the proper circuit is used, as in Fig. 2, and care is taken in the tune-up and operation.

Operation

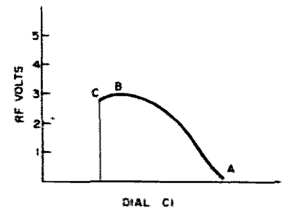
This circuit is for use with crystals of the overtone type, in which the quartz is ground for operation with more than one half sound wave (which makes the presence of a tuned circuit on the inscribed frequency an absolute "must").

Referring to Fig. 2, when assembled and wired, and tested with an ohmmeter for proper resistance values and possible shorts, a milliammeter may be shunted across S1 or put in series with the battery. Some 2 to 5 mA should flow. This will vary with the strength of oscillation, due to the positioning of the FB (feedback) control tap on L1, the setting of C1, and of course, Re, the resistor emitter. I generally connect a 1k variable resistor, known in the trade as a "pot" (potentiometer), in series with a 100 Ohm "safety" resistor to the emitter, and then, after suitable tests to determine the current and overall action desired, I wire in a fixed resistor. However, in this case, for an oscillator designed for experimental testing over a wide range of crystals and frequencies, the potentiometer proved so valuable that it was left in circuit. The Fig. 2 oscillator should now be working.

Two home brew pieces of test equipment are shown, the aperiodic (untuned) diode rf voltmeter in Fig. 3, and the TD (tuned diode) voltmeter and frequency meter in Fig. 4. Both figures contain enough information to enable you to build at least experimental models of these test units. The TD in particular is quite valuable for checking the frequency of an oscillator and the relative powers in the harmonics. Don't forget that almost all oscillators are operating class C and therefore may have strong harmonics. The second and third harmonics are also particularly useful in getting crystal control up beyond 50 MHz. These harmonics are picked out, amplified, and filtered, and then the higher harmonics of the first frequency multiplier are picked out, amplified, etc., etc., resulting at last in crystal control on the radar frequencies (and higher). This requires frequency multipliers, of course.

Referring again to the Fig. 2 circuit, actually the most important of this article, the tuning of C1 and L1 should be done with care. When operating correctly, C1 is not critical, but as you are going

Fig. 5. Tuning curve of C1, Fig. 2 (without LPC).



to use and test several crystals, or maybe a lot of them, and thus be checking widely separated, it is important to get acquainted with just how a good crystal oscillator works. Don't try to figure out how an oscillator starts! Just assume it is running, and it will be if you follow all details and proceed from there. Insert an overtone crystal, 21 MHz for example, and tune C1 and L1 back and forth through the 21 MHz range. I found good oscillation starting at 2 mA, with about one volt dc showing on the TD connected to the output J1 by a cable of 50 Ohms. "Pushing" the oscillator, by lowering R1 to 470 Ohms, with a total battery current of 4 to 5 mA, caused 3 volts to show on the TD. You can push it even more, to 7 mA, and some 5 volts will show on the TD. However, I just checked the Q1 I was using because it did not start easily, and found that replacing it with an "FCS 9011 H 209" led to much better reliability. So, don't push these little semiconductors too far in power! Note that this type of tester is also useful for testing transistors. Indeed, I generally test out three or four and label them "good 50 MHz osc." or whatever they may be.

Voltmeter readings showed B+ of 8.5; on E there was 1.6, and on the base, 2 volts. Note that the "regular" type of tuning showing on C1 causes gradual rising output as you approach maximum from the higher C side, and an abrupt cutoff of oscillation as you pass the maximum peak on the low side. Fig. 5 shows this curve, which is the

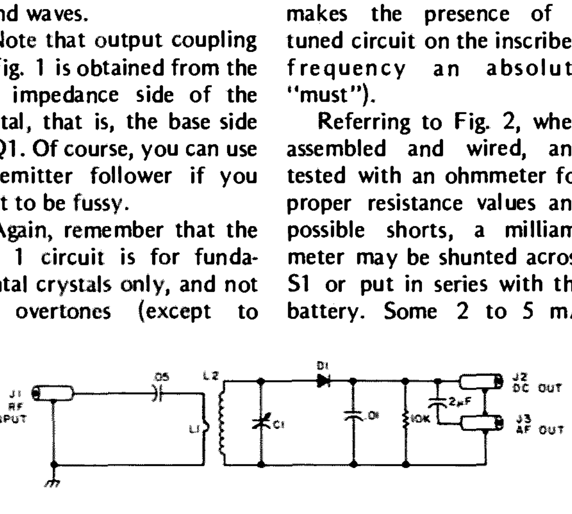


Fig. 4. Tuned diode rf voltmeter. L1 – 1 turn. L2 – to suit frequency. C1 – 465 pF.

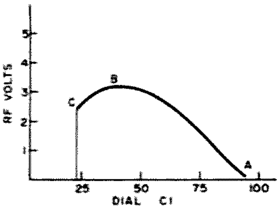
Fig. 6. Tuning curve of C1, Fig. 2 (with LPC).



normal and correct type for an overtone oscillator. Get used to it, and note that for reliable starting you should not operate on the peak at C. Use some position near B, as you will find in a short session of trials by turning the battery switch on and off and watching the output. Note that Fig. 5 is just one curve that I found here using a 45 MHz rock designed for two meter (146 MHz) work, and different crystals and transistors (and different feedback taps on L1) may show somewhat different curves.

A very interesting addition to Fig. 2 can be made as follows. A small coil of fine wire, some 40 turns on a matchstick, 4 mm long by 2 mm diameter, can be added simply in series with the crystal, on either the base side or the coil (L1) side. The effect of this coil (labeled "LPC") is quite interesting. It corrects the phase shift through the collector-L1-crystal-base path, and results in stronger oscillation and easier and more reliable starting. It also shows up in a much more uniform curve when plotted as in Fig. 6. The tuning will no longer show an abrupt drop on the low C side. Trying out several sizes of these "phase correction coils" will show you quite a bit about phasing in oscillators.

Checking out the rest of my VHF crystals, the operation was similar, although on 75 MHz oscillations did not start until I used some 2½ mA on the oscillator. ■

TTL Techniques

- - bypass those glitches

William Browning WB5IRY
516 N. 95th E. Ave.
Tulsa OK 74115

TTL logic is one of the most popular of all logic families. One reason for this is that it will almost always work even when the circuits that are in use are of poor engineering design.

If you saw some of the experimental circuits that I have put together, it would be obvious why I like this feature. But TTL, like all electronic devices, will at least be more reliable if proper engineering design is used.

What is proper design for TTL? I wondered this same thing for a long time. If you would like to know some of what I found out, read on.

The (Vcc) supply voltage for TTL is +5 volts and should be well regulated, with ripple of less than 5%. If you are using a large system, a low inductance power busing system is recommended.

Every circuit board should have decoupling capacitors — at least one for every 5 to 10 TTL ICs, and one for every flip-flop. These should be .01 uF to .1 uF rf bypass capacitors with short leads. There should also be at least one 2 uF to 20 uF on each board. For a general rule, the more capacitors, the better.

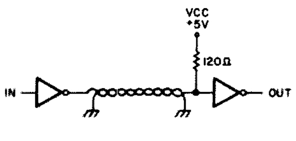


Fig. 1.

A good ground bus should be used whenever possible (essential for large systems). Better yet would be the use of a ground plane. Stay away from using open wire connections for grounds.

Use printed circuit board construction for all circuits, and stay away from hand-wired construction. IC sockets are fine most of the time, but they may cost more than the ICs that they hold.

Don't follow the common practice of leaving unused inputs floating. Though they do normally assume a logic 1, they also act as an antenna for noise and the floating input may go to a logic 0 at any time. You may tie inputs to ground for a permanent logic 0, or to Vcc through a 1k Ohm current limiting resistor for a permanent logic 1. One current limiting resistor can be used for up to 50 inputs.

If you have any unused gates, it is recommended that the output be forced to a logic 1 by tying of the inputs. This will give lower power dissipation and you can use the permanent logic 1 for the tying of other gate inputs.

When open wire connections become necessary, they should not be routed together. They should be kept as short as possible. If long runs of wire are required, it is best to use twisted pairs. One possible way to drive a long run of twisted pairs is shown in Fig. 1.

The next time a TTL project does not seem to work right, or works right only part of the time, check it for the engineering design. You just may find the problem.

If you are doing design work yourself — and what project-building ham doesn't? — just eliminate some of the possible problems to start with. ■

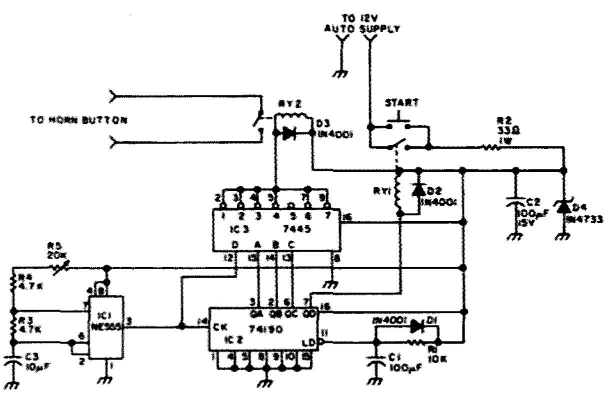
James F. Reid W8LWS
4 Lawn Street
Ashley OH 43003

Sending HI

-- on the hooter

Remember the good old days when hams would toot HI, in Morse code, on their automobile horns when spying one of their cohorts? Why don't they do this any more? Is the dastardly rumor true? Don't hams know the Morse code or has that esprit de corps, peculiar to hams, gone the way of home brew rigs and sunspots? The little goody described herein won't bring back the sunspots but will put you on the road to home brew rigs and will allow you to send HI on your automobile horn with just one push of your pinky. This unit utilizes electron flow to accomplish this worthy purpose. You remember electrons, don't you? They're some of that electricity stuff.

This circuit can be divided into four main sections: an oscillator (IC1), a counter (IC2), a decoder (IC3) and a power supply latch and regulator. The oscillator rate and the rate at which you send HI can be adjusted by R5. I found that after I had used the unit for a short while, I didn't want to adjust the rate any more, so R5 might just as well be a trim pot hidden out of sight. The start pushbutton is the only thing that needs to be accessible.



When the start pushbutton is pushed, 12 volts from the car battery is dropped through R2 and regulated to 5.1 volts by the zener D4. C2 keeps any noise from the automobile system from causing problems as well as providing a low impedance power source for the ICs.

When 5 volts is applied to the ICs, the network of R1 and C1 causes the voltage on pin 11 of IC2 to rise more slowly than the supply voltage, and thus performs the function of clearing the counter to all zeros. The diode D1 causes the capacitor C1 to discharge rapidly when the power is removed so that the circuit will be ready for a new cycle of operation very soon. With the output Q_D in a low state, the relay RY1 is energized and the 12 volt power is maintained to the circuit even though the start push-button is released. The oscillator performs two functions. It advances the counter every time the oscillator output makes a low to high transition, and it enables the decoder whenever the oscillator output is high. Since the oscillator output spends half of its cycle time high and the other half of its cycle time low, the counter retains a particular count for a complete cycle of the oscillator while the decoder IC3 is enabled for only half of the cycle time. This provides that each dot will be followed by a space of equal duration. As the counter starts counting up from zero, the decoder outputs go low one at a time. The output corresponding to the count in the counter activates relay RY2 and the relay contacts toot the horn. Only the first three bits of the counter are decoded and the outputs 1 through 7 are the only decoder outputs used to activate RY2. Output 5 is not used and this is the space between the H and the I. When pin 12 of the decoder goes high with the oscillator output, the decoder interprets this as a number greater than 7 and none of the outputs connected to RY2 can go low. When the counter goes to a count of 8, output Q_D goes high, which releases RY1 and removes all power from the circuit. This means that you can leave this unit connected to the car battery all the time since it only draws power when it is in actual operation (which means this design is ecologically sound, whatever that means). If you hold the button down, you will send HIs ad nauseam. ■

Build a DDRR for Your Mobile

- - this one won't blow off

When I moved to a new mobile home park a few years ago, a new and formidable kind of antenna problem faced me. The park rules forbade my normal array of antennas. After sitting around lusting for forty meter phone for a while, I decided forty meters wouldn't be the same without me, and I had to do something to get back on the air.

I tried the usual non-working, "invisible" wire antennas with 10:1 swrs, and a home brew joy stick that was tricky to load and produced rf burns at the microphone (it is hard to enunciate with Band-Aids on the lips), but it was obvious – there had to be a better way. There was. I discovered, in a June, 1970, *73 Magazine*, the DDRR (Discontinuous Directional Ring Radiator) antenna.[1]

The first thing I had to consider was what size DDRR would be needed for forty meters. My calculations produced a height of twelve inches and a diameter of nine feet. Just right for my twelve-foot-wide mobile home! And I had another bonus: The home roof was metal and would make an ideal ground plane for the antenna. I had only to supply the radiating element, and bingo – on the air!

The next thing I had to do was convince the park officials that an antenna only one foot high sure wouldn't look like an antenna. Subsequent conversations with the park manager produced permission to put it up, since, "It sure wouldn't look like an antenna." We had reached an understanding. Construction proceeded at full speed.

I had lots of ½ inch copper tubing left after setting up my home in its new location, but not enough to make a complete antenna. A trip to the hardware store produced a few more feet of tubing, an in-line coupler, a tee-coupler, and a deep appreciation for the similarity between the price of copper and gold. I put all the copper under lock and key until the antenna went up.

Since the antenna radiator wasn't self-supporting, I had to design a framework to hold it in position. PVC tubing is rather cheap, and since I am too, another trip to the hardware store produced a PVC four-way connector, several ten foot lengths of ½ inch i.d. PVC tubing, and four right angle PVC connectors. The four-way connector was the center of the support structure. The PVC pipes, cut to 4.5 foot lengths, were inserted into the connector. Holes were drilled through the connector limbs and pipe, and 6-32 screws were inserted through the limbs and pipe. This prevented the pipes from twisting in the connector. The right angle connectors, after being mounted on the four pipe sections, were squared vertically and drilled through. 6-32 screws were inserted.

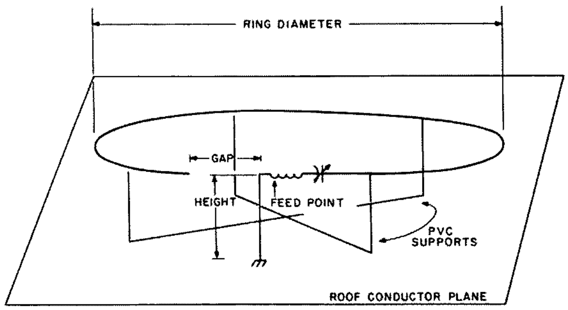

Fig. 1. Schematic layout of the final antenna and support parts. The PVC four-way connector is located in the support center. The right angle connectors form the upright bends.

The PVC uprights, twelve inches long, were cut with a hacksaw to form slots on the end to hold the radiator while the other end was pushed into the right angle connector. The antenna was now ready for final assembly.

All the parts were collected on the roof after the copper tubing sections were joined and bent into a first order approximation of a nine foot circle. On the ground, the tubing measured 27.2 feet with a one foot discontinuity, but after carrying it up the ladder, the roundness became more approximate. A copper tee-section was soldered to a copper tube with a flattened section bent at a right angle to the rod. The distance from the bend to the tee-section was twelve inches. The radiator was placed on the supports and re-rounded to take out the strain on the supports. The whole arrangement was centered on the roof. The copper upright was soldered to the main radiator, and a hole was drilled through the flattened section on the upright and the roof. The contact area of the flange and roof was cleaned carefully on both metal surfaces, and a large sheet metal screw run through both. The connection site was caulked and covered with putty and painted with some roofing paint.

Nylon lines extending from the center of the support frame (the four-way connector) to some convenient tie points on the roof held the assembly in place. The wind wouldn't blow this project away, and where I live you have to think seriously about such things.

A variable capacitor of about 100 pF was placed on the end of the radiator at the discontinuity, and the other plates on the capacitor were grounded. An SO-239, mounted near the base of the copper upright, was connected to the antenna via some solid copper wire. Last of all, the rig was brought up on the roof, along with some power, lights, and a real sense of anticipation. Now was the moment of truth.

An swr meter was inserted in the line close to the antenna, and the rig was turned on. There was a little noise coming from the speaker, but not much to cheer about. I tuned the capacitor, and suddenly I could hear good, loud signals coming through. The tuning was sharp, but boy did it work!

I loaded the rig into a fifty Ohm dummy load, connected it to the antenna again, and inserted some carrier. The roof lit up like Broadway, with a bluish cast. My capacitor was a beacon in the night as rf buzzed between the plates. The capacitor was the correct value, but the voltage rating was far too low.

I started a search into every junk box I was privy to. No dice. Seems no one uses high voltage capacitors any more. With transistors and two meter FM, high voltage capacitors are joining the dinosaurs in extinction. The alternative was to make one.

Choosing the sturdiest-looking peanut butter jar in stock (I save such things), I mounted a long screw through the lid, put a foil-covered paper cup on the screw head, and dropped the whole thing inside the jar.

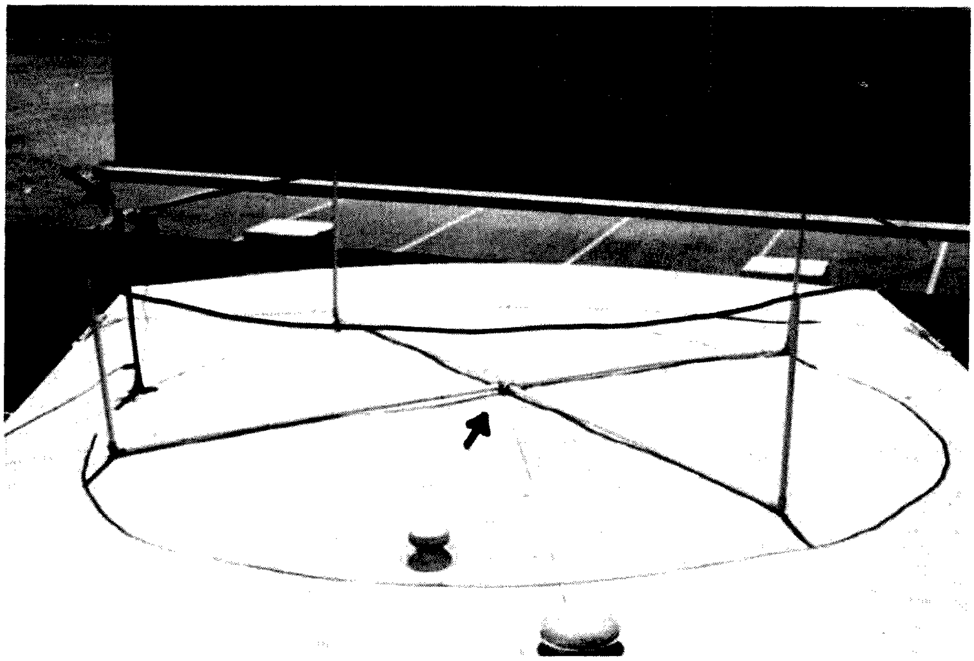

Fig. 2. Final DDRR positioning on the roof. The antenna is two feet high. The tuning capacitor and coil can be seen on the left. Nylon lines run to the PVC four-way connector in the center.

The outside of the jar was covered with foil, and connection to the foil was made with some copper wire twisted around the foil on the jar. I mounted the capacitor, tuned it, and, joy of joys, it worked! A great sense of foxiness overwhelmed me, and I bragged wildly to my XYL for fifteen minutes or so before returning to my triumph on the roof.

I tuned up the transmitter, and applied a little power to the antenna again. The swr was about 10:1, but that could be adjusted later, I thought. However, I had second thoughts about it and brought the swr down to 3:1 by changing the tap point on the antenna. At about fifty Watts into the final amplifier, the whole thing cracked like a rifle. I ducked and headed for the power switch. The capacitor was shattered as if it had been hit by a hammer. As I looked at my broken success story, it started to snow, and it really became imperative to get off the roof before the rig and I both slid off. The moral of this short story is that a lot of voltage appears at that discontinuity, so have a healthy respect for it. Capacitors at the discontinuity had better be able to handle 3 kV or more.

Fortunately, my reference for this project didn't let me down. It described another loading technique, and, since I had put more than my weekly allowance into the copper tubing, I wasn't about to quit now. Besides, I was getting questions from the neighbors about my new solar heating unit on the roof. I smiled knowingly and talked about heating the world.

Meanwhile, my junk box yielded some three-inch-diameter B & W stock, and a call on two meters produced a nice 200 pF variable from a very disbelieving ham. I disconnected the tee-section from the radiator and inserted a PVC section into the gap for support. The coil was soldered to the tee-section and the variable capacitor, after the capacitor had been mounted to the radiator with some machine screws. The combination formed a series-tuned circuit and provided a handy tap point for the coax. This technique isn't as efficient as the one which lighted the sky, but the tuning capacitor sees smaller voltages which are more manageable. The final arrangement is diagrammed in Fig. 1.

The resulting combination tuned easily, with the characteristic sharp increase in noise at resonance. The coil was then stepwise shorted, and the capacitor tuned to provide the highest C to L ratio with a little room for tuning. Some ten turns of coil remained unshorted.

The final tuning process was a combination of tuning for minimum swr and moving the tap point until the returning energy was minimum. I ended up with no measurable reflected swr at resonance. It pays not to hurry through these adjustments.

Set the resonant point at your favorite spot on the band (you are building one, aren't you?) and don't expect to stray far beyond that. The

	10	15	20	40
Ring Diameter	28″	40″	54″	108″
Antenna Height	3″	4.75″	6″	12″
Discontinuity (Gap)	2″	2.5″	3″	5″

Table 1. Dimensions for other bands.

the roof. The PVC support system can be easily seen. Fig. 3 gives an idea of how the antenna could appear on your home. In case you are interested in other bands, some suggested dimensions are shown in Table 1.

In the December, 1975, *QST*, John Belrose analyzed this kind of antenna, and, from the analysis, he has suggested a new name for it.[2] I ignored the name (apologies to John) and moved to a very instructive graph that plotted the height of the antenna in degrees versus radiation efficiency. That graph, plus some thinking on my part, produced another antenna party on the roof, this time to raise the whole thing another twelve inches. Doing that, according to the graph, would (could) raise the radiation efficiency some 4-plus dB. Everything went up a foot. The results have been gratifying, with fewer CQs and calls in the log that have a "no QSO" notation.

For those hams who live in mobile home communities with antenna restrictions, this kind of antenna might get you back on the air. I can vouchsafe one product of building and tuning such an antenna: You will end up knowing a great deal more about antennas than when you started the project. ■

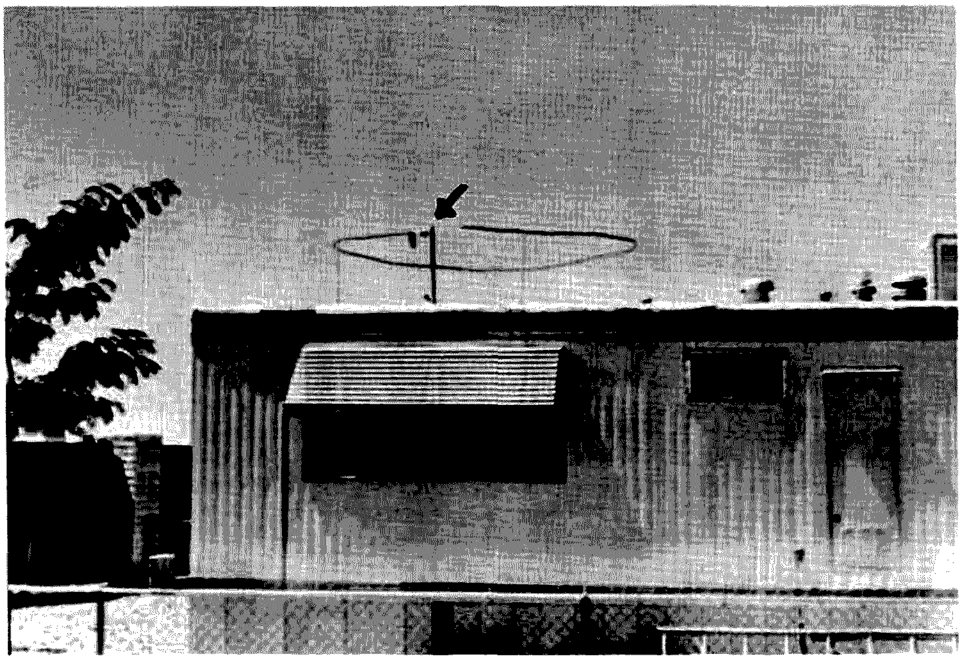

Fig. 3. The elegant look of success: the DDRR on the roof. Vertical portion of the radiator and tuning section are quite visible. Call it a solar heater.

final adjustment provided about 40 kHz of operation around 7250 kHz for a vswr measured at 2:1 or less. Considering the alternative of no operation, I viewed this as only a minor annoyance.

The antenna has operated at this QTH for over a year and a half and has satisfied the objective of keeping me on the air. Plus, it has proved to be quite a stimulant to conversation during QSOs. There is always the suspicion, with any antenna you build, that it's really just heating the air rather than radiating electromagnetic energy. This antenna, too, has fallen under that suspicion, but every time my doubts have risen, the DDRR comes through with a nice solid contact into eastern Canada, or Puget Sound, Washington.

I recently put up a temporary vertical for forty meters and tuned it for an swr measured close to 1.1:1. Switching between the two antennas produced a real surprise. The DDRR worked as well as the vertical for getting the signal out, and reported signal strengths for both of them were indistinguishable. However, the DDRR proved to be exceptionally quiet! A noise level of S5 or S6 on the vertical was S1 to 2 on the DDRR, but the received signal levels were identical.

I have worked both coasts with 5/9-plus reports, with 60 to 100 Watts PEP at the antenna. I have worked mobiles others cannot hear because of the QRN. On my vertical I can't copy them either, but they are Q5 and S2 on the DDRR.

My vertical sits in the corner a lot of the time now, awaiting portable or emergency use. The DDRR sits on the roof at dc ground potential (no static electricity buildup from the wind) and won't blow away, and if I get a little more inventive, remote tuning will let me walk all over the forty meter band.

Fig. 2 shows the final positioning of my little gem on the roof.

Headphone Jack Adapter

David Naatz WAØVHX
RFD 5, Box 237
Austin MN 55912

Have you ever bought a good pair of headphones for your ham set that work with your AM/FM radio or tape recorder, only to be confronted with a monstrous ¼" plug? Well, here is a setup that may help.

This is also a handy adapter to have lying around for that "once-in-a-lifetime" chance that you won't have a speaker or headphones and want to get on the air.

That happened to me as I came home from college, but forgot to bring home a speaker or 'phones. I used this adapter in conjunction with some 2,000 Ohm earphones that I had used with an old Japanese transistor radio. ■

Automatic Taping Unit

- - for repeaters, logging, etc.

This unit has been developed for sticky-beaking on selected FM channels. It has a number of useful functions for the experimenter.

Basically it is a unit for turning on a tape recorder whenever an input signal is received by the receiver and turning the tape off again when the signal goes off — after recording the audio from the transmission. Applications are many. The local repeater can be monitored unattended. Information such as daily usage rate, overnight use, callsigns of all users and so on can all be analyzed. It enables an experimenter while out mobile to hear his signals replayed when reaching home. Other stations can leave messages for you with this system.

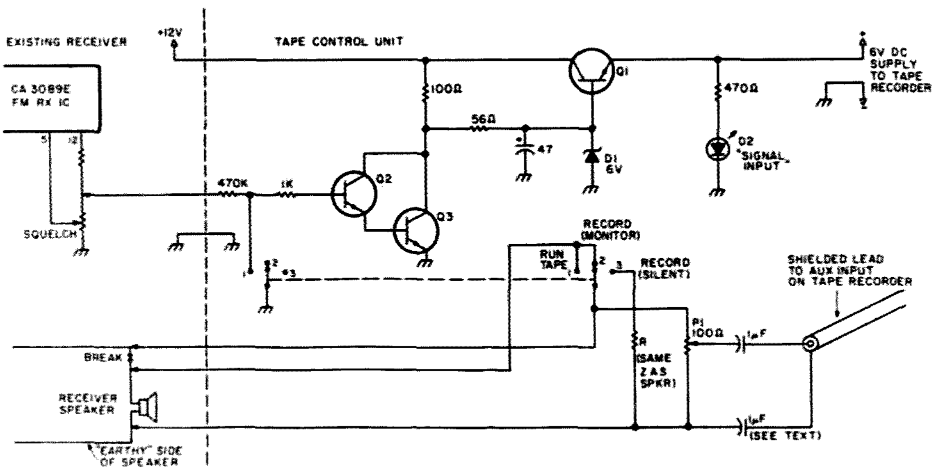
The tape recorder used is a cheap cassette with autostop. The autostop is a desirable feature so that the recorder turns itself off when the tape has run out. The circuit could be adapted to other types of recorders. A 6 volt dc supply is necessary for the recorder used in the example described here. This supply is obtained by a series regulator Q1 and zener diode D1 from the 12 volt receiver supply.

Transistors Q2 and Q3 are a Darlington pair which, when conducting, effectively remove the base supply for Q1 and turn the tape off. If the base of Q2 is positive, the tape is off. If the base of Q2 is at earth, the tape operates.

The receiver in use has a CA3089E in the i-f tail-end. Connection to the mute (or squelch) circuitry is as shown in the diagram. Other receivers could be connected up in some similar way. The 470k resistor and Darlington connection of Q2 and Q3 ensure negligible loading of the squelch circuitry. No mechanical relays are necessary.

The control switch in position 1 enables the tape recorder to be run for rewind and replay. The LED gives visual indication of an input signal entering the system. This is of use when recording in the "silent" position of the control switch.

Audio from the receiver is taken from the speaker circuit and fed to the input of the recorder. A resistor (of the same impedance as the receiver speaker) is switched into the circuit when the control switch is in position 3. This keeps the shack silent during unattended recording. In positions 1 and 2 of the switch, the receiver speaker is active. The receiver speaker monitors receiver activity



during rewind and replay to ensure that nothing is missed!

Potentiometer P1 sets the audio to a suitable level for the recorder input. The receiver audio gain control must have already been set for comfortable room listening. The two capacitors in the audio leads to the tape recorder input are necessary to ensure complete dc isolation of the receiver from the recorder. Some recorders are positive earth, while most receivers are negative earth. Provided that this problem is recognized and investigated with appropriate steps taken if found to be necessary, then no difficulties should arise. My recorder is positive earth, but it is in a plastic case with few metal protrusions, so the whole thing "dc floats" quite acceptably.

This monitoring system has been running successfully for some years now and has been useful for keeping up-to-date with current happenings on the channel and for testing purposes. It is much more acceptable to record your own signal when testing or developing transmitters and hear it later yourself than to rely entirely on verbal assessments from other operators.

Transistor Q1 is an NPN power transistor. Q2 and Q3 are NPN small-signal types. There are so many suitable types of transistors available for these applications that no type numbers are quoted here.

This tape control system is also useful when out mobile. It can be run quite conveniently in a car. When the vehicle is parked, it can be set operational, and you can soon learn if someone has called you during your absence.

Construction is not critical in any way and any suitable board or box or chassis will be suitable. Junk box parts will invariably be found to be appropriate!

Good luck and good listening!■

Let's Use English

-- for a change

CBers are known for their CB lingo, the jargon they like to use. They use a handle – a nickname that they use only on the air, like "Red Baron" or "Big Breaker." Their language is colorful: "18 wheeler" instead of "truck," "10-4" instead of "OK." There are even dictionaries of CB slang being published.

As far as I am concerned, this is foolishness. CBers are people talking to other people – why shouldn't they use the same language as everyone else?

We hams are almost as bad. Our peculiar language includes such things as "What's your QTH?" or "Thanks for the fine Q sew." Most of our contacts involve a lot of jargon, but we manage to get some English in, so listeners can at least tell what language we are speaking.

There was a time when ham talk had its place, on CW. Abbreviations and short cuts are the order of the day on CW, but to carry them over into speech is silly. The only reason we keep using a peculiar form of talking is that it sets us apart, it makes us a select group, with our own practices.

I propose that we stop using oddball terms like QTH, QRMary and XYL, and stick to terms that we have understood since childhood, like hometown, interference, and wife. As a group we have nothing to set us apart. Oh yes, we all managed to pass a code and theory test that wasn't that much of a challenge; then we went out and bought our rigs, set them up, and started talking. We're not really into this radio thing too technically. If we were, I could understand us talking shop, using technical terms.

Why did we get into ham radio at all? To join a group that is set apart by its strange practices, or for the thrill of being able to talk with some one across the state while seated in our car, or across the world from the home station? I think you know why. So what happened? When we first became hams we wanted very much to join the group and be like everyone else. So we imitated what we heard. We adopted the practices we heard on the bands. We learned to say "The QTH here is . . .", "The handle here is . . .", "See you further on down the log." That gave us a feeling of belonging, and made us feel like old pros on the band.

Now that CB has become the latest national fad, and its weird ways of talking are being heard on the streets and on TV, many of us hams have seen how silly it is and how little we need our own peculiar jargon. We can make sense to each other by using everyday English, the same language we use everywhere else. So how about it? How about going up or down in frequency instead of QS whying? "Further on down the mike cord" should become "Some other time." Let's lay QRMary to rest, alongside QRNancy. No more talk about XYLs or Q sews. Come on, hams, let's hear it for good old standard English! ■

The Ham Radio Classroom

- - sure beats study hall

I shoved the key in the lock and twisted. Then I put my shoulder against the panel and kicked the bottom of the door with the heel of my shoe. It opened with a groan. That door, like everything else at Riverside Vo-Tech High School, was badly in need of repair.

Heels clicked on hard tile. I paused, turned, and gazed as the chic YL figure passed.

"Hi," she tossed a breezy greeting.

"Evening," I managed to get out.

She continued on down the hall, hips swaying provocatively. I pursed my lips in a soundless wolf whistle, and fumed at myself for acting like a high school freshman.

I was there that evening to get my ham rig set up and checked out for class demonstrations the next day. I had no idea what Leigh Wainright was doing in the building. For that matter, I had never been able to figure out why a dish like Leigh was teaching Home Ec in a crummy school like Riverside.

I turned back toward my room. It was hard to realize only two months had passed since I accepted the job as electronics instructor, and had my name, Kenneth Cook, inscribed on a cardboard tab over the door.

My eyes took in the familiar scene. Tables and chairs in the middle of the room, where students were supposed to study and take notes. A bench down each wall with a few test instruments, mostly government surplus. Junk TVs and radios, which should have been scrapped years before. And a green portable chalkboard, covered with illustrations and basic formulas.

Maybe, just maybe, I thought, I could get those kids interested in Ohm's Law or how to make a good solder joint, if I showed them how much fun ham radio could be.

So far it looked as if trying to teach them anything was a waste of time. The school was practically an armed camp, where keeping a semblance of order was the major task each day.

Although teaching jobs were not plentiful, I could have been working elsewhere, either as an instructor or technician, for more money than Riverside paid. But I had chosen to hunt a position in an urban poverty area school where I felt I could be of service – maybe help some of those less fortunate find a better life.

And what career was more wide open than electronics, in this day of integrated circuits and microprocessors.

As I thought, I kept busy, securing the coax I had strung the evening before from a dipole on the roof, along the wall. I had decided to set up on 40. A 2 or 6 meter rig would not impress the kids as much as talking to someone at a distance. 20 was too crowded with no beam. 40 looked like the right compromise between distance and reliability.

I made the final connection between my transceiver and home brew linear, plugged in the mike, and flipped a switch. I found an open spot on the band and checked the swr.

A "5" called a short CQ. I went back to him.

My cares and worries dropped away. No matter how down I was, I could fire up a rig and forget my problems. It had always been like that, even when I was a kid playing with crystal sets and code practice oscillators.

I had my General before I was fifteen and nothing, absolutely nothing, had ever come ahead of hamming. This included girls, which was probably the reason I was still single at the ripe old age of twenty-four.

I was right in the middle of a long-winded explanation of what I hoped to accomplish at the school when my door rattled violently.

"Wait one, Joe," I spoke into the mike and across three states.

A lift and pull at the door was necessary from the inside, before it opened. I looked into a pair of blazing violet eyes.

"Mister Cook," Leigh Wainright exclaimed. "We're trying to watch a slide presentation, and all we can hear on the sound system is you!"

"Sorry."

I had learned long ago there was no use arguing with anyone, especially when they were angry, concerning TVI, BCI, or any other kind of interference. "Just give me a minute and I'll sign off."

She nodded and I ended the QSO briefly.

"I'll have to work on the sound system," I told her. "I'm planning on a club station and we won't want to be interfering."

"Nothing wrong with the PA," Leigh insisted, "except when you have that thing going."

Again, there was no use arguing. I changed the subject.

"What kind of slide show are you watching?"

"Presenting," she corrected me. The expression on her perfectly molded face was incredulous. "You really don't know?"

I shook my head.

"Teachers Association," she said tersely.

I decided her complexion wasn't perfect. She had two freckles on the end of her turned-up nose.

"Oh, the union thing."

Violet eyes blazed again. "Yes, the union thing. If you

want to see how underpaid and overworked you are, and how our educational system in this state compares with other states, why don't you come and watch?"

"Might as well," I grinned, "since you've put me off the air."

The Home Ec department was at the other end of the building. I had to walk faster than my usual ambling gait to keep up with her. I didn't tell her the reason I agreed to attend the meeting was because of her, not the union. I didn't have anything against unions. I knew they had done a lot of good, but I always had the idea they were for truck drivers, carpenters, and other trades, not for teachers.

"I'm surprised you're allowed to hold a union meeting in the school building," I made conversation.

"Mr. Higdon's on our side," Leigh replied, "even though he can't say so. He just conveniently looks the other direction."

Higdon was the principal. As far as I could see, he always looked the other direction when anything came up. Especially anything that required spending any money, like parts I needed, or books, or test equipment.

I sat through the slide presentation and listened to Leigh Wainright's perfectly modulated voice cite reams of facts and figures. A lot of what she said made sense. It was ridiculous that the lowest paid sanitation worker had take-home pay greater than a beginning teacher.

But I confess I was more interested in the curve of Leigh Wainright's slender throat, silhouetted by the projector light, than by the cause she espoused.

Finally the presentation was over. Bright lights flashed on.

"Well," Leigh Wainright concluded, "are we willing to do whatever we have to, to see these injustices are corrected?"

A chorus of "yeahs," "Yesses," and "You tell 'em, Leigh," rang out.

A man I recognized as a science teacher jumped to his feet. "Strike," he yelled. "I say, let's strike."

"Not so fast," Leigh shot back. "A strike is the last resort."

They wrangled for several minutes. There was no doubt about the sentiment. 90% of the teachers were 100% activists.

It was also very apparent that Leigh Wainright was Miss Big in the Teachers Union.

Slowly the room cleared. I lingered until only Leigh, I, and two burly men were left.

"Mr. Cook, I want you to meet Mr. Summers and Mr. Cannon," Leigh introduced them.

"Jake Summers," the older of the two stuck out his hand. He was fat and bald. "Pleased to meetchu."

"Likewise," Cannon said. He would have been handsome, in a swarthy kind of way, if it had not been for a white ragged scar across his left cheek.

"These gentlemen are from headquarters," Leigh explained.

Both were impeccably dressed, but I though they could have passed as fugitives from a chain gang. But the union men were of little interest to me.

I was tuned to resonance on Leigh Wainright's wavelength. I screwed up my courage. Nothing ventured, nothing gained, I told myself.

"Miss Wainright – Leigh," I finally stammered. "Could I – that is – do you need a lift home?"

"I have my car."

I knew she did. My heart's S-meter dropped to zero.

"But if you want to follow, we could stop for a Coke," she added.

Did I want to? You bet your sweet one and only 4CX1000 I wanted to!

A short time later, facing Leigh across a table, I listened for the second time to her union sales pitch. "And we *will* strike if we have to," she concluded.

"What about the kids?" I objected. "Is a strike fair to them?"

"As fair as what the city fathers are doing to us – and to them."

I still didn't agree, but I was willing to discuss it all night, just for the privilege of sitting and watching the sparkle in her violet eyes, and the bounce of her blond hair. Finally the subject of the union was exhausted. We really began to get acquainted. Before we parted I had a date for the next evening.

The following morning I had the attention of the entire class, at least for a few minutes, when I fired up the rig. I caught a "4" in Florida who was willing to rag chew. I explained what we were doing and even let some of the students say a few words, after explaining this was permissible, as I was actually operating the equipment.

The students seemed to be fascinated as much by the VOX as by the QSO itself.

"Well?" I queried, after I signed and turned down the receiver gain.

"That was really somethin'," one of the two girls in my class exclaimed. "'Specially the way your voice turns everything on and off."

"Yeah," Russell Allen, a boy who had been even more of a problem student than others, interjected. "But how you make any bread, man, outta just talkin'?"

"You don't make money," I explained. "In fact, it is against the law to use amateur radio for commercial purposes. But you can learn – how to build, adjust, and maintain radio transmitters and receivers. There are millions of jobs in related fields: police radio, taxicabs, broadcast, TV . . ."

I waxed eloquent, "Why, hams have always been pioneers, opening up frequencies once considered worthless."

I stopped, knowing he would not understand about frequencies. "I learned most of what I know working with ham radio," I finished. "I could hold down almost any kind of electronics job, and be making a lot of money."

Russ pounced on my words. His brown eyes danced and his chocolate face displayed an insolent grin. "Then how come you're here, teach?"

There was nothing stupid about Russ Allen. I desperately wanted to reach him, to help him, but I felt frustrated.

"Money isn't everything," I finally replied. "I'm here because I want to do something useful."

"If you ain't here for the bread, how come you gonna strike?"

So the strike talk had got back to the students.

"Nobody said I was."

"You gonna scab?"

I knew the conversation was going far beyond the area where it should have been allowed, but I had let it go too far to stop.

"I'll be here to teach any day the school is open," I told him. "Now, how about you? Are you going to take advantage of your opportunity for an education?"

"I be here," he said, "if you be."

That night my date with Leigh Wainright went as smooth as a local 2 meter QSO. For the first time in my life, I found myself more interested in a girl than my radio equipment.

It happened sooner or later to most good hams, I excused myself, judging by the number of XYLs and junior ops.

I went to a number of union meetings with Leigh, at various locations throughout the city. Each was a repeat of the one at Riverside, although the teachers at Riverside were by far the most militant. At each meeting the two organizers, Jake Summers and Art Cannon, were present. But I could not see that they took

any active part.

Once I tried to explain ham radio to Leigh. She echoed Russ Allen's thoughts.

"But Ken, what good is it?"

I repeated all I had said to Russ and added:

"Hams handle all kinds of emergency messages during floods, tornadoes, ice storms, and so forth. Many have emergency power. Countless lives have been saved and literally millions of messages have been handled for the Red Cross or branches of the military. The Army, Air Force, and Navy all recognize the value of hams and have their own ham organizations – The Military Affiliate Radio Service – MARS."

She may have been impressed, but she failed to show it. However, I knew she was uptight over the union thing.

"We have this local net right here in the city," I went on. "We meet every Friday night . . ."

"Meet? Where?" she interrupted. "Would they be interested in seeing my slides?"

I laughed. "We meet on the air for an emergency drill."

"Oh," she said, "just a bunch of radio nuts."

For the first time, I was angry with her. "Ham radio operators include some of the finest and best-known people in the world," I snapped. "People like Arthur Godfrey and Barry Goldwater. Doctors, lawyers, teachers, politicians, businessmen, policemen – you name it. I'm new in this city, but I'm willing to bet you'll find every profession I named on the net!"

"Sorry," she said, "I didn't mean to rile you."

"Would you like to listen when it's my night to call the net?"

She nodded, but without enthusiasm.

I continued seeing Leigh Wainright almost every evening. Thoughts of a home and family life were very much a part of each day.

Strike talk waxed hot. I helped Leigh draw up a list of demands. Truthfully, nothing asked was unreasonable, except perhaps the dues check-off – whether a teacher chose to belong to the union or not. And even that was a matter of opinion.

The list was duly submitted to the School Board and passed up to the Mayor and Commissioners.

In the meantime, I moved more of my personal equipment into my room at school. I set up my two and six meter FM rigs. Beams were not necessary because of the repeaters. Both rigs were VOX controlled. I had always been a nut about that, so I could keep both hands free to solder or wire while operating.

Finally, it seemed, I was at last creating some student interest. I didn't know if the ham demonstrations deserved the credit, or if I had, somehow, at least partially, won their trust.

In spite of dating, I still managed to meet the net. Leigh Wainright or no Leigh Wainright, I had no intention of abdicating this responsibility. On several occasions I found Russ waiting for me outside the school. He puttered in the shop, soldering on a code practice oscillator and listening as the net progressed.

Then negotiations began to break down between the teachers organization and the School Board.

Leigh Wainright was totally committed to teachers' rights.

I found out she had chosen a position at Riverside because she wanted to expose the conditions there, which were worse than they were in any other school in the city. I could see she was becoming more and more frustrated.

One afternoon she told me, "I'm sorry, Ken. I can't be with you tonight. We have a showdown meeting with the School Board. The way it looks now we'll be on strike tomorrow!"

I hadn't thought much about the possibility of a strike. I figured they would work something out. And if the worse came to worst, those who wanted to strike would stay home and those who didn't, wouldn't.

I seldom watched TV and nothing prepared me for the scene outside the school the next morning.

The crowd was immense. Students, parents, police, reporters, TV crews, and teachers milled about. The teachers moved in a circle, carrying placards which proclaimed their grievances. Leigh Wainright headed the marchers.

She saw me and waved a hand in greeting.

The din was intense. Parents shouted obscenities. Teachers replied. Students, looking forward to a holiday, agitated by throwing an occasional rock or bottle from time to time at the cordon of police who stood between them and the teachers.

"You goin' in, teach?" I heard a familiar voice inquire. The arrogant smirk I remembered was on Russ Allen's face.

I had not known until that minute what I would do.

I squared my shoulders. "I'm going in."

"Wait," Russ instructed.

He moved about swiftly and was back in a couple of minutes with three of my students.

"This is all," he said.

I led the way. We moved toward the cordon of police. Two stepped forward to meet us.

"I'm a teacher," I said. "I'm not striking. We're going in."

"We can't guarantee your safety!"

"We're going in," I repeated.

Their ranks parted slowly. We moved forward, up to the line of marching strikers. I met Leigh Wainright, face to face.

"Ken," she gasped.

"I'm going in," I told her. "The children's education is more important than anything else."

The look on her face told plainer than words how she felt.

Police parted the marchers. We slipped through onto the school grounds. I noted a couple of other teachers and a dozen students followed us.

Then I spied Summers and Cannon. They stepped from the line and moved quickly alongside of me, one on each side.

"Friend," Jake said, "ain't you makin' a slight mistake?"

Cannon seized my arm. His hand was like a vise. "Breakin' a picket line could be downright unhealthy, friend."

"Besides, what will your little woman think?" Jake added.

I shook them off and trudged ahead. Now I knew the function of the two: muscle men, when the going got rough.

The day was a washout as far as any actual work on lessons was concerned. But I sensed a new respect from Russ Allen and the other three students. Once he put his thoughts in words:

"You really ain't here just for the bread, teach!"

"I need money to live same as anyone else," I replied. "But educating America's future citizens seems more important to me than the size of the salary."

He nodded, solemnly.

That afternoon, getting out of school was as much an ordeal as getting in. The police surrounded us completely and escorted us through the crowds.

The next day we knew what to expect, and took our lunch. Six teachers and maybe fifty students crossed the picket lines with us. And the day following, more than 100 students and several additional teachers.

The contempt in Leigh Wainright's eyes was almost more than I could bear. But there was nothing I could do.

She thought she was right. I felt I was.

That afternoon things appeared even more hectic. Boos were plentiful and obscene gestures the order of the day as our little band, encircled by police, started across no man's land, away from the school.

Then shouts and yells arose. Several people surrounded a police car and began rocking it. More swarmed around and the car was turned onto its side.

Our escort rushed toward that mob, and the striking teachers headed for me. I felt a blow in my stomach, and caught a glimpse of Cannon as I went down. Then feet were tromping. I realized the people had gone mad as blackness closed around me.

When I awoke, it took seconds to realize who I was, minutes before the wail of a siren and the motion of a vehicle penetrated my mind. I was flat on my back on a stretcher.

Then I thought it had to be a dream as part of that dream spoke:

"Ken. Thank God, Ken. Are you all right?"

"I am now," I told Leigh Wainright. "That is, if I'm even here." Then memory hit me. "The kids? Other people? How many were hurt?"

She shook visibly. "Too many. Maybe I've been wrong, Ken. I never knew people could go crazy."

"Not people," I said. "Mobs."

"When I saw you — all hurt like that ...," she choked. I reached for her hand.

At the hospital they checked me over, patched me up and checked me in. I had cuts and bruises, and a lump on the head, but no broken bones. But they insisted I remain overnight for observation.

Leigh stayed until they ran her off.

"See you in the morning at school," I told her.

"Ken, no," she remonstrated. "Haven't you had enough?"

I shook my head.

She kissed me before she went out the door. Once again I slept with visions of a blond, violet-eyed XYL and six junior ops running through my dreams.

They released me early the next morning. I went directly to the school. The scene was much subdued from the day before. It was as if the mob had run out of steam after blowing a pop valve.

A few teachers still marched. Leigh Wainright was not one of them. I looked about for familiar faces and was relieved to see the bushy Afro and intelligent brown eyes of Russ Allen. He wore a bandage on one cheek and one arm was in a sling.

"Ready, teach?"

"Ready," I said.

The students bunched behind me as we walked toward the picket line. No words were spoken as we crossed the street. As we approached the picket line, I heard Leigh cry out from behind me:

"Ken! Wait!"

She joined us and I reached for her hand.

"I-I'm still for the teachers," she said, "but I can't be a part of violence."

"You wanted to call attention to conditions here at Riverside," I told her. "And I guess you've done that."

"The wrong kind of publicity," she said bitterly. "People who saw those news films on TV will think teachers are a bunch of wild animals."

That morning, almost a third of the teachers and student body entered the building. It was my guess the strike was all but over. And little, or nothing, had been accomplished.

But one good thing had come out of it. I had gained the respect of my students. Russ Allen was the prime example. He listened to every word I spoke, and I knew he was convinced I was sincere in the work I was doing.

Leigh spent most of the day observing my class, since none of her students were present. She was impressed at the eagerness Russ and the other students displayed.

That morning and again in the afternoon, I fired up the rig and we talked to people in six different states.

"Tonight's my night to call the 2 meter net," I told Leigh. "Want to sit in?"

"Here?"

I nodded.

"Can we get in the building?"

I shrugged. "Why not? I get in every day, and the picket line is only during school hours."

"I'd love to," she agreed.

That night I picked Leigh up early and we drove slowly to the school. There was no indication a strike was in progress. But as we parked, a police car cruised by, circled, and came back. We identified ourselves. In a couple of minutes Russ joined us and we proceeded into the building.

A school security guard intercepted us at the door, but he knew us and we exchanged greetings as I reset the lock.

"Better keep everything locked," he advised. "We ain't takin' no chances."

"I think the strike's about over," I replied.

"Me, too," he agreed. "And I'm plenty glad. My old lady's scared to death I'll get hurt or somethin'."

"I was, too," I confided. "And then I was."

We laughed together. I invited him to join us for a while when he made his rounds.

The door to my room, after the usual sequence, opened. I snapped on the light and fired up the 2 meter rig. It was not quite net time, and the usual pre-net chitchat was in progress.

I explained the VOX system to Leigh, and told her how autopatch worked.

Russ made the necessary entries in my log book. I opened the net and began roll call. I was about a third of the way down the list when my door rattled violently.

"Wait one," I said into the mike. Habit caused me to rotate the receiver gain to "0" before I went to the door. I lifted and pulled, expecting to see the security guard.

"Well, ain't this a party?" Jake Summers snarled as the door swung open.

He pushed past me. Cannon followed. The younger man's hand closed in a vise-like grip around my arm. "Friend, didn't we tell you crossing a picket line could be unhealthy?"

"Jake! Art! What is the meaning of this?" Leigh demanded.

Both men laughed. "Now, sister. You didn't think we could let you welsh on our deal, did you?" Jake sneered.

"You'd better leave," I tried to make my voice firm. "The security man will be here in a few minutes."

"He ain't likely to be nowhere for a long time, friend."

Out of the corner of an eye I saw Russ move toward the transmitter. I thought I knew what he was trying to do. I began struggling. I had to keep the thugs' eyes off the boy.

Cannon's hand found my throat, and Jake landed a kick in my groin. But I had seen Russ's hand turn up the mike gain before he glided away.

"What we gonna do about the boy?" Jake demanded.

I heard a faint click as I doubled over. The VOX relay had kicked in. I prayed they hadn't noticed.

"We got no choice," Cannon snapped. "We ain't gonna leave no witness."

Russ's eyes were wide and round. "I don't hear nothin'," he said. "I don't see nothin'. I don't say nothin'!"

"W-What do you intend to do — with us?" Leigh asked.

They didn't answer.

"Listen," I shouted, before the delay unlatched. "You can't break into River-

side Vo-Tech and kidnap us — maybe murder us — and get away with it. People know where we are. They'll be here in a hurry. Jake Summers, you tried to kill me yesterday. You didn't make it. You won't get away with it today!"

"Shut up," Jake growled.

"Come on," Cannon snarled. "Let's get out of here."

He hauled out a snub-nosed revolver from beneath his coat and waved toward the door.

"You, too," he told Russ.

"Please, Mister. Don't make me go. I ain't gonna say nothin'."

Again, Cannon waved the pistol toward the door. Russ dropped to the floor and began yelling.

"Help, somebody, please! They gonna kill us. They gonna take us away and kill us, right now!"

Russ was the picture of a genuinely terrified boy, and I couldn't blame him, for I wasn't exactly comfortable about the situation. But he knew he was "on the air," and no actor ever gave a better performance.

Jake landed a solid kick in the boy's side. Russ quieted as suddenly as he had begun. He staggered to his feet and lurched out the door.

Cannon twisted my arm behind my back and forced me forward into the hall. Jake prodded Leigh, who was sobbing softly.

I knew how terrified she was and I longed to comfort her. But there was no way I could let her know we had been telling more than fifty ham radio operators what was happening.

We moved down the hall, not toward the front of the building, but in the direction of the Home Ec department.

"Look," I said. "You need Miss Wainright. She hasn't quit the union. Let her go. She just came in this morning to watch me operate my ham rig."

"Shut up, punk," Cannon growled.

We reached Leigh's room. Jake opened the door with a key he took from his pocket.

Leigh hung her head. "I let them have my keyring one night to come after a projector. They must have had duplicates made."

So they had simply unlocked a door and walked in, I thought. I remembered the security guard, and how he had met us at the door. Then what Cannon had said.

They herded us across the room toward a window. Jake raised it, listened, shoved a big foot against the rotting screen, then climbed through.

"All right, sister," Cannon ordered.

Russ was next and I followed him.

The grounds were dark. We moved slowly, past the cafeteria, in the direction of the football field.

Had I miscalculated? Had the net members decided the real life drama relayed by our two meter repeater was a hoax?

I couldn't believe it, yet where were the police?

Then I heard something. Cannon heard it too.

"What was that?" He stopped.

"Garbage pail," I said. "Probably a dog."

After a long moment we moved forward again.

All at once I heard a welcome sound. The whoop-whoop and wail of a siren. Faint, but building. Then it sounded as if half the police force was approaching.

Two things happened almost at the same time. Cannon and Jake turned to run. I stuck a foot in front of the fat man, and he tumbled to the ground. Several figures popped up from behind the garbage cans.

"Stop or I'll shoot," one yelled.

Cannon swung toward the man, the revolver in his hand. A slim figure hurtled past me and into the thug's side.

Russ knew how to tackle.

Flashlights came on and a policeman got handcuffs on the two muscle men. Then the officer turned to me.

"Hi, Ken," he said. "I'm WA9———. I was just coming off duty and caught the excitement on my mobile rig."

"Boy, am I ever glad to see you," I said, and added, "this is Leigh Wainright. Leigh, this is Bob, one of the net members. You didn't realize it, but the VOX circuit kept my transmitter on all the time we were in my classroom.

Others crowded around, introducing themselves. Police began arriving by the dozen. Bob explained he had used the autopatch in his car to call them while en route.

Somebody said they had found the security guard, trussed up, and with a lump on his head, but otherwise OK.

The police took Summers and Cannon away, after telling us to report to police headquarters and give our statements the next morning.

By that time there were at least a couple of dozen hams milling about.

"What say we go to the radio room for an eyeball?" I suggested.

Everybody agreed.

Leigh Wainright had recovered her poise completely. She detoured through the Home Ec department and picked up a coffee pot. Soon, one would have thought we were at the end, or the beginning, of a big hamfest.

Hams kept coming until the room was overflowing.

Somebody fired up my rig and soon the word was passed to the shut-ins and distant net members.

Of course I had to go over what had happened several times, including Russ's cool and shrewd thinking.

One thing led to another. I began to tell them what I had accomplished with the students by using ham radio. Then Leigh took over and was soon conducting a tour of Riverside, pointing out all the glaring deficiencies.

I noticed one of the hams taking notes, and I remembered the boast I had made to Leigh about finding people from all walks of life on our two meter net.

When we got back to my classroom I conducted a poll. We had one newspaper reporter, seven doctors, one man who was an aide in the Mayor's office, four druggists, two plumbers, three policemen, fourteen people connected with radio and TV stations (mostly engineers), five lawyers, four teachers (two college level), forty-one who were businessmen or worked at various other positions, and, believe it or not, one *School Board member!*

"Just a bunch of radio nuts," I whispered to Leigh. "Do you think you could ever learn to love one?"

"Oh, Ken" was her only comment. But the look on her face gave me the answer I wanted. That was three years ago.

We now have one junior op and another on the way. Leigh got her ham ticket a year after we were married.

I wish I could say the ham School Board member and the ham newsman gave us enough publicity that all ills at Riverside Vo-Tech were cured.

But it didn't work that way.

True, we got good publicity, and the support of the media. Some improvements were made, and we got a small raise in pay.

As usual, everything in life was a compromise.

One interesting thing came to light.

Jake Summers and Art Cannon both had felony records, and were not official representatives of the National Teacher's Organization. They were part of a wildcat, militant union and had lied to Leigh, intending to use the union as a base of operation to further some nefarious scheme.

Russ Allen graduated from Riverside with honors, and most of my classes are now there to learn.

I give ham radio the credit. Wouldn't you? ■

CB to 10 -- A Legal Alternative

-- part I: bandplan and crystal info

For some time now, there has been an ever-growing concern over the outcome of the ten meter band. The ham use of the band has dropped over the past several years due to sunspot activity to a point where other services, mainly Citizens Band, feel that the frequencies could be put to better use. I remember when I used to work into Europe daily with five Watts and a dipole on CW and AM, and even into ZL and VK land after I got up a 3 element "plumber's delight" beam.

The sunspot cycle, though probably not as good as the one back in the late 1940's, is about to open the band up again. Many groups are presently getting ready for better activity on ten with the establishment of nets and even new repeaters.

The above is the whole idea behind this article: an easy way to get back on 10 meters with low power with a small outlay of cash.

When the FCC announced that they were increasing the Citizens Band from 23 channels to the current 40 channels effective January 1, 1977, the prices started to drop on the 23 channel units. If indications here apply to the country as a whole, a lot of hams started picking up these cheap rigs with the idea of first going on CB in their cars to keep track of traffic, and secondly, someday converting the CB rig for use on other bands, namely 10 meters.

Also, there seems to be a large influx of former CBers giving up the ranks of CB and going on to amateur radio. Over 80% of the new hams in the Mobile, Alabama, area are former CBers who wanted to get away from the QRM on 11 meters. Most of these former CBers still have their old CB rigs stored away in their junk boxes. They have picked up the ham habit of never throwing away anything that might be usable some time in the far distant future. Now is the time to drag out that old 11 meter rig and convert it to 10 meters on crystal controlled channels that could become standard all over the country.

The first thing that has to be done to make the whole idea of getting low power transceivers to work is to establish some simple ground rules. If every person converting a CB rig for 10 meters picks frequencies at random, very little activity will result. I would like to therefore suggest some standard blocks of channels (frequencies) that could be used to increase the effectiveness of these low powered rigs. With both the Novice and Technician class license holders on 10 meter CW, it can be seen that there

		Converted Ten Meter Frequencies		
Channel	Original Frequency (MHz)	Novice/Tech Frequency (MHz)	AM Phone Frequency (MHz)	SSB Phone Frequency (MHz)
1	26.965	28.005*	28.705	28.505

Fig. 2. NOTE: With this many different i-f combinations being used, it is necessary that exact specifications of the transceiver to be converted are known.

must be a block of channels that they can use when they convert a CB rig to CW operation. There is unwritten use of SSB only on the low frequency end of the 10 meter phone band, so the SSB CB rigs that are converted should have a block and, of course, the bulk of the converted CB rigs, being inexpensive AM rigs, will need their channel allocations. Fig. 1 lists all three of the groups of 23 channels that could be used.

The very nature of the basic CB transceiver makes this type unit one of the simplest to convert to ten meter operation. In the case of other types of low power surplus equipment that has been available in the past, the tunable stages have been fairly narrow, but in the case of the CB rig, the tuned stages are fairly broad. To fulfill the requirement of being channel selectable without being tunable by the operator, most CB rigs on the market today will give close to 4 Watts output at both extremes of frequency, that is, at channel 1 and channel 23.

After reviewing the crystal requirements of over 1200 different CB transceivers, I was able to arrive at the common configuration for both transmit and receive crystals. Every transceiver reviewed fell into one of the configurations shown in Fig. 2, where "F" indicates the output frequency desired.

The frequency combinations shown in Fig. 2 are for CB transceivers that use a single crystal for each transmit channel and another crystal for each received frequency. This type of transceiver can be modified for use on 10 meters, but the expense would probably be more than buying or building a simple 10 meter transmitter and simple converter for use with an existing receiver. The possibility of building a simple VFO to replace the crystals in the transmitter and receiver sections of this type of transceiver would solve the problem of the large numbers of crystals needed.

There are two other

groups of transceivers available on the market at the present that could be modified. First of these is the synthesized units which use combinations of a small number of crystals to obtain all of the transmit and receive frequencies desired. The second class of transceiver available is the phase locked loop or PLL type that uses very few crystals and digital frequency generation to obtain the frequencies needed.

The combinations used for the synthesized units are almost without limit. When converting a transceiver of this type, it would be of necessity to obtain a complete schematic and parts list for the unit from the manufacturer or one of the CB service type books on the market listing your transceiver. Though the synthesized type is cheaper to modify than the type using crystals for each frequency, there could be problems in obtaining the necessary information to determine the crystals needed.

In Fig. 3, I have listed several of the more common synthesized units available and crystal data necessary to convert the units to 10 meters. Fig. 3 is divided into 3 parts for ease of understanding.

The crystal combinations listed in Fig. 3 are examples of some that will be encountered when trying to shift an eleven meter CB transceiver to the 10 meter band. I have found that the simplest way to calculate the frequencies needed is to use only channel 1 to determine a simple formula. Once a formula is obtained, each crystal frequency can be found. The best way to select which oscillator you want to shift is to select the one that requires the least number of crystals to make up the greatest number of frequencies.

The Cobra 138, Cobra 139, Midland 13-895, Pace 1000B, or the Pace 1000M should prove fine choices for conversion to 10 meter SSB. In each of these, the original 7.8025 MHz crystal is the only crystal that needs to be changed. It seems logical that a multiple deck crystal switch/socket package could be used. This arrangement would allow several 23 channel arrangements over the 10 meter SSB segment. For example: Selection of the lower end frequencies of 28503 kHz, 28505 kHz, 28507 kHz, and 28510 kHz would require only 4 crystals for a total of 92 channels between 28503 kHz and 28800 kHz.

There are several linear amplifiers on the market today which are smaller than most CB transceivers and have output of 50 to 100 Watts. Of course, most of these units are rated as 3 to 30 MHz "ham" amplifiers which actually only work well between 26 and 30 MHz. These small amplifiers could be used to increase the mobile or fixed capability of the converted transceiver.

The final type of CB transceiver that can be modified for 10 meters is the PLL type. These are more expensive than the other two types for several reasons. The PLL is the easiest to modify by the CBer for operation on frequencies other than the 23 or 40 channels for which the unit was built. This type of unit is the easiest for the manufacturer to convert to 40 channel operation. This ease is, of course, the major reason that this type of transceiver lends itself to modification to the 10 meter ham band.

I have selected 8 different models of PLL transceivers that are available to show what can be done to modify this type of transceiver for 10 meter use. Fig. 4 lists the PLL transceivers and the crystals that are presently used for generation of the necessary signals for 11 meter CB operation.

By referring to the original frequencies of the CB trans-

Fig. 4.

ceivers as listed in Fig. 1, various shifts in oscillator frequencies can be obtained. The intent of this article is not to give a step-by-step conversion of CB transceivers to 10 meters, but instead only to tell what can be done with the available units on the market.

In the case of the PLL transceiver, it will become a matter of experimentation to determine the exact frequencies needed. I recommend that anyone attempting to convert a PLL transceiver become very familiar with PLL circuits in general. In the type of transceiver requiring only crystal changes to change the output frequency, the processes are simple. In the case of the PLL circuit, the problems that can be encountered in digital development of the frequencies needed are best solved by the more expert in the ham ranks. The conversion of a PLL transceiver is not a project that should be tackled by the new ham or one with little or no knowledge of solid state devices.

There are several things that must be taken into account before you attempt conversion of any CB transceiver for operation on the 10 meter band. Mainly these can be grouped into a few simple questions:

1. How much do I want to spend if I have to buy a new or used CB transceiver?
2. Does the CB transceiver I presently have lend itself to easy and cheap conversion?
3. How much electronics knowledge do I have to solve the problems I will encounter?
4. Do I feel that 10 meters is worth all the effort to convert a CB rig to that band?

If all of these questions can be answered in such a way to indicate that your next project is to be the conversion of a CB transceiver for 10 meters, then get started before the band starts to open up for some rare DX. ■

Save Your Old Speakers

-- how to remove the beehive

In the old days, service technicians did a lot of speaker cone recentering to clear up annoying rattles, which was at the time a tedious but possible job.

Current speakers generally make speakers throw-away, due to their modern design, so they're "go or no go" devices. There is, however, a possible cure if the rattle is due to an off-center voice coil and it's a fast repair.

Remove the speaker. Hold it close to your ear and gently, with fingertips, alternately press and release the cone about an inch from the rim toward the voice coil and listen for scratchy sound. Rotate the speaker while doing this. If the speaker is capable of this fast cure, you will find the noise limited to one point on the circumference. Carefully note that point. Lay speaker on a solid flat surface, with magnet up. Then use a heavy rubber mallet to strike the magnet end a sharp blow or two at a point directly opposite to point where the scratch was heard. Don't get over-ambitious with pounding. A few lighter raps are far better than one hefty wallop. In effect, you are recentering a misaligned voice coil. Result is usually a clear-up of the rattle. ■

Beware the Compressor!

- - some pitfalls to avoid

Robert B. Lunsford, Jr. WB5QGI
1405 Stephen
Killeen TX 76541

Speech compressors really work! Using one on 10 meters with a friend about 8 miles away, I found that the average level nearly equaled the average level obtained when switching on and off a 1200 Watt amplifier. The objection is that a) The background noise may be excessive unless some care is exercised in adjustment; b) Enough distortion is introduced from the compressor that it may even be objectionable or unpleasant to delicate or sensitive ears (again, careful adjustment may be the answer); and c) The problem of congestion on the bands is not addressed with a compressor, in fact, it is sometimes made worse by signals being too wide – again an adjustment problem, usually.

The third reason given above is probably the best known by amateurs in general. There is also a small amount of interference noticed by some, that of detecting a portion of the unwanted sideband when using an SSB station. The problem here is usually at the transmitter, but the point is that it exists!

Another form of interference to the SSB operator is that of another station moving into about 2 kHz of your frequency, which is referred to as "Alligator Teeth." Not only is it distracting, you sometimes find yourself attempting to copy both the station you are in contact with and the adjacent station.

Herein I will outline an idea and a concept which the reader and experimenter should be aware of and, perhaps in the not too distant future, the concept will be put into action by some of the more adventurous and innovative amateurs. I will be using it myself, but I believe that when the concept is understood, not only will it be used by amateurs, but also by the military and by commercial communications systems.

In order to understand the idea of band compression, some background preparation is in order. No doubt there are some readers with insight and experience who could proceed at once to the block diagrams and read the conclusion. Others could probably say they thought about something similar in the past and may have surpassed me in the initial design. This is encouraged. In fact, I hope and expect to see specific diagrams and schematics in the future that will enable anyone to duplicate the circuitry.

Unless the reader has had some experience with linguistics, foreign language, or has had extensive English study, the vital parts of communication must now be covered.

In the English language, as well as many others, the S and Z sounds (voiced and unvoiced hissing sounds) contribute the most to the *understandability* of verbal communications. These sounds lie in the frequency range above 1 kHz, and below 1 kHz are the explosive sounds such as B, T, D, M, N, L, K, G, F, and P. There exist languages in the world that are made up of the explosive sounds alone, and the frequencies above about 1 kHz are not vital to verbal communications. Granted, the upper frequencies are necessary for providing depth and naturalness to the human voice, but as far as communications are concerned, we can get along without the upper frequencies. However, we must have some way of signaling to our ears when the high frequencies (the S and Z sounds) are part of the verbal communication.

Moving right along, a glance at Fig. 1 will now give the reader a preliminary understanding of the band compression concept. Following the signal from the antenna through the receiver, a frequency splitter using active filters will pass the frequencies from 300-1000 Hz, but will attenuate the frequencies above and below. However, the frequencies *above* 1 kHz (with a cutoff of about 2.5 kHz) will signal or gate a white noise generator. This white noise will be adjustable for naturalness and will signify the S and Z sounds by a hissing sound.

The combination of the white noise generator's output and the 300-1000 Hz frequencies are made in the mixer where the strength or relationship of the two signals is effected. The audio amplifier rounds out the receiver system.

By this time, the idea should be firming up. The transmitter block diagram is shown in Fig. 2 and is nothing but the reverse of the receiver's signal processing.

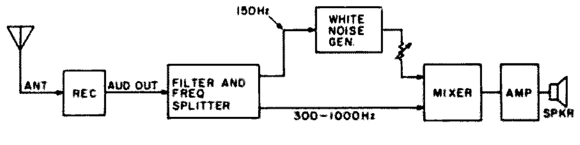

Fig. 1. Receiving block diagram.

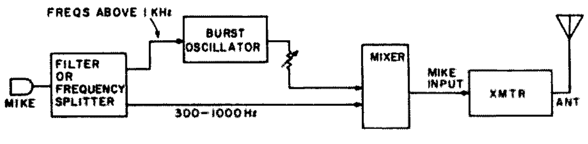

Fig. 2. Transmitter block diagram.

Fig. 3. Rough spectrum representation.

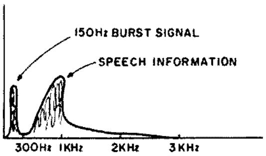

Fig. 4. Noise generator circuit. Note: Values of output components will be selected during breadboarding (C1 and R1).

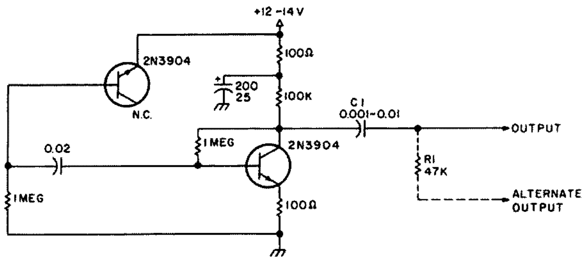

The frequency splitter passes those frequencies between 300 and 1000 Hz and senses those frequencies above 1 kHz (with a cutoff at about 2.5 kHz). The signal sensing frequencies above 1 kHz trigger or gate a burst oscillator which I've arbitrarily chosen to be set at 150 Hz. The mixer then combines the two frequencies and the microphone input will have a signal roughly conceived and shown in Fig. 3, with a 150 Hz triggering signal and those frequencies between 300 and 1000 Hz being transmitted.

Now, before you say this will give an effective bandwidth of 1 kHz, it must be noted that due to combining the two signals and the inherent mixing processes, the total effective bandwidth is closer to 1 kHz plus 150 Hz, or approximately 1.2 kHz, to be safe, could be considered the overall bandwidth. It should be understood that we would not be using pulse modulation, since those frequencies above 1 kHz have been merely attenuated and could be recovered by amplification of the upper frequencies. Also, since the usage of S and Z sounds is so entirely random in natural conversation, band compression would not detract excessively from the usually less than ideal conditions on the bands using single sideband.

My reason for not being specific with schematics, printed circuit board layouts, parts list, etc., is that not only am I plowed under with projects, but I also believe that there are many fertile minds in amateur radio that not only could conceive the project, but also could breadboard and build it. I have included a white noise generator circuit which is known to work; however, the gating and level setting circuitry will have to be designed. All experimentation could even be done by using two tape recorders, but it must be remembered that this will not be high fidelity. If high fidelity is desired, go to 2 meters (where, coincidentally, I've noticed some use of speech compressors, much to the detriment of the inherent quality of voice communications).

Conclusion

In the history of radio communications, there have been repeated cycles of refinement and improvement. First, we had spark or "noise generators," which were replaced by vacuum tube oscillators and tuned circuits, making them cover a smaller frequency spectrum. Then came voice communications. Amplitude modulation was, and still is to some extent, a good means of communication. With congestion beginning to build up, other means of communication were sought, however, and with wire communication pioneering, double and single sideband transmission were studied as an alternative. The state of the art was refined as oscillators became more stable, materials became available, and construction methods were standardized. The military demand for the best available communications equipment produced unequaled models for others to follow, when considering the period in which they were designed.

The world of communications is again at a turning point. Amateurs are able to "make do" by using maximum usable frequency techniques and by selective listening, but this only serves to refine one's operating. With the congestion apparent at the lower frequencies, an approach allowing less adjacent frequency interference and therefore more effective usage of the amateur bands would seem to be very desirable.

We as amateur radio operators are concerned with "getting the message through." By using band compression, we would not be bothered by adjacent channel interference. However, in the future, another problem will surely consume us if we do not move with the times, and this is super-saturation. More compactness in our frequency bands will be necessary and this is why I use the term "band compression." The challenge is before us and amateurs could find themselves the pioneers once again.

I would like to express my thanks to Ken Frank WB5AKI for his understanding and encouragement in the band compression project. We have intentions of building and testing the concept and may later be able to provide more data, schematics, etc. You would then see them in *73 Magazine*, unless some other fellow amateur beats us to it! ■

Matching Output Transformers

When installing multi-tapped output transformers, it is often confusing to try to follow charts and, in some cases, an incorrect match is made due to not knowing voice coil impedance. To avoid this, and obtain a perfect match, connect one terminal of the transformer to one side of the voice coil. Connect an output meter across the voice coil. Introduce a 400 cycle audio signal to the detector with enough attenuation to show a low reading on output meter with probe on any lug. Then, with a probe clipped to open side of voice coil, touch each lug on secondary of transformer in turn with the probe, noting change in meter reading.

The combination of lugs giving highest reading is the nearest match and will give maximum efficiency. This can be done with any multi-tapped audio transformer and applies to either primary or secondary. ■

Stop Timeouts!

-- build this 10 minute ID timer

I would like to say, at the outset, that there is nothing new or original about this timer. All the bits and pieces were stolen from various magazines and books. However, I must modestly admit I designed what I wanted and made it work.

Of all the timers I have ever built before, none really ever satisfied me. I have built the tube type and the solid state type using the RC timing method, but their accuracy leaves something to be desired and they are difficult to adjust to the ten minute time period.

Being LED readout happy, I decided to build a ten minute readout timer that would read out the minutes, recycle after ten minutes, shut off the alarm after two or three seconds, and could be manually reset at any time. This is a lazy man's timer that can be built for less than a thousand dollars.

The problems in building the counter were numerous, because I am a raw beginner and do not pretend to know what goes on inside those little black boxes. Previous to this project, I marked the fronts of all my magazines with IC circuits that interested me, along with the page numbers (e.g., all 555 timer circuits and 4700 bounceless switch circuits, etc.). Then I armed myself with about twenty dollars worth of books, of which the *TTL Cookbook* proved to have the most information in terms that I could almost understand.

I sent away for the ICs and sockets from the ads in the backs of the magazines and bought the balance of the goodies at our local Radio Shack. I had some junk on hand and used that where possible. The Radio Shack salesman asked me what I was building. After I gave him all the glowing details, he said, "How about one of these mechanical timers for $3.50?" I already had about ten bucks worth of stuff between my thumb and forefinger, and thought to myself, "I wouldn't want this character working for me." He said "It's all solid state." Then I knew he was pulling my leg. I told him no self-respecting ham would use a mechanical timer — it isn't sophisticated enough for the state of the art. This sophistication does cost more, but I decided to go first class.

I built the enclosure out of 3/8" thick walnut and copied the metal cabinet design of those cute miniboxes with the slanted overhang in the front. If you decide to build your enclosure, the vectorboard used for the ICs and wiring was 4-1/2" wide by 5-7/8" long, and the 4 spacers or legs under the board were 1/2" high. I kept these spacers as short as possible to keep my nosy friends from getting a good view of the sloppy wiring job. The bottom of the enclosure is 4-5/8" wide by 6-1/2" long, the ends are 4-5/8" wide by 3-3/8" high, the top is 4-5/8" wide by 7-7/8" long, and the sides are 3-11/16" high by 7-7/8" long. I sanded the walnut lumber first with #80 grit paper, followed with #120 grit, and finished with #220 grit. I glued the ends onto the bottom section (using no nails) and kept it in the vise for 24 hours to dry. The sides are glued to the top section in the same manner. After this section dried, I cut the front at an angle to give that overhang effect. The finish on the cabinet is hand-rubbed like the finest furniture.

I used Radio Shack's .1" vectorboard for construction, keeping all components above the board and the rat's nest below. I ran reset, ground, and positive bare buses of solid #20 copper wire as near the ICs as possible, and threaded them up and down through the holes to hold them firmly in place. The readout was fastened to a small piece of vectorboard about 1-1/2" square using an IC socket and fastening all 1/4 Watt resistors on the same board. All wires that leave the board were the stranded type, for flexibility. This makes it easier to fit the readout to the hole in the panel and to hook up the speaker and controls. I left these wires objec-

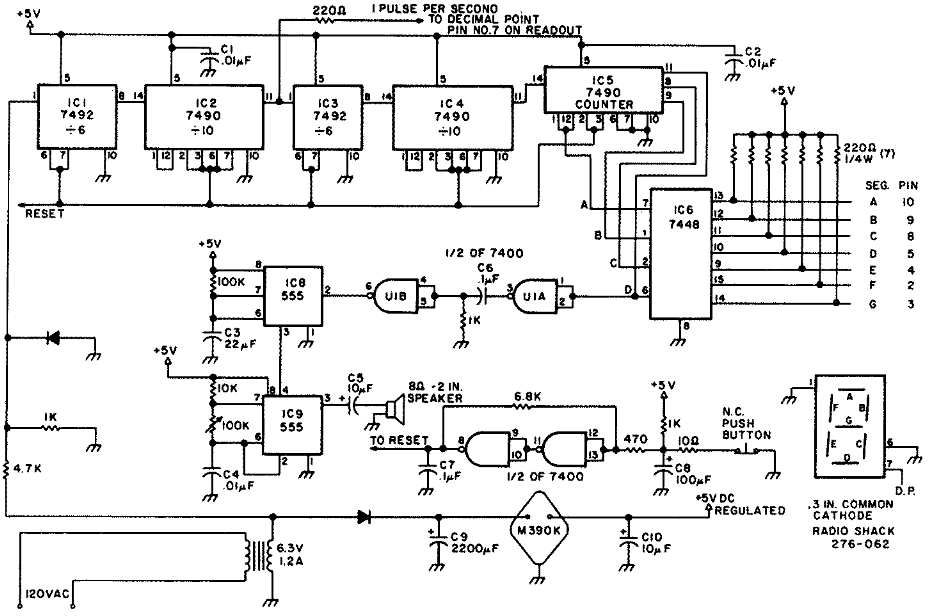

Fig. 1. Ten minute ID timer.

tionably long so I could assemble them out of the cabinet and get the circuit board in and out of the cabinet without a fight. At this time I must admit there was an architectural mistake in the design of the cabinet. The front is too thick to accept the tone control and the push-button switch. I had anticipated this and made the front 1/4" thick, but I still had to chisel out enough wood to make them reach.

The speaker is mounted on the rear of the cabinet with three thumbtacks. It is an 8 Ohm 2" Radio Shack speaker. The voltage regulator is mounted on the left side of the rear cabinet. The heat sink is a piece of 1/8" scrap aluminum with mounting holes drilled to match the mounting holes in the regulator. There was a mechanical engineering problem here, however. The regulator is slightly dome-shaped, and the point of the dome just touched the aluminum when the regulator was drawn down tight with sheet metal screws. I healed this problem by folding some aluminum foil into a thick pad, placing it in between, and drawing it down tight.

The power supply is simple and easy to build. The despiker capacitors are perhaps the most important items in the project. I believe all the problems that I describe later could have been avoided if I had included them in the first failure. The diodes are from my junk box – the bullet type. The voltage regulator is an M390K, but any 5 volt 1 Amp job could be used. The filter capacitor could be increased to 3000 uF as the power supply voltage is at the bare minimum.

The 60 Hertz line frequency is divided by IC1 and IC2 to give a one second pulse. This is connected to the decimal point on the readout through a 220 Ohm 1/4 Watt resistor, and pulses every second to give an indication that the timer is working. This one second pulse is then divided by IC3 and IC4 to give a one minute pulse or, to be more exact, to give a pulse every minute. The one minute pulses are then counted by IC5, and its binary output is fed into IC6, which drives the seven segment readout. I used a 7448 driver and a common cathode readout because I had them on hand. Most circuits use a 7447 driver with a common anode readout, and use series resistors to limit the current in the segments. I tried my readout without any resistors by hooking it up direct, but it wasn't bright enough. I experimented with various pull up resistors, starting at 500 Ohms and working my way down until I was satisfied with the brightness. I settled for 220 Ohms, as I had a lot of them on hand (the segments were drawing 15 mA current with a maximum rating of 25 mA). This is a very nice, clear, bright readout, and not very expensive.

IC7 is a 555 timer wired in the monostable mode with RC values to give a 2.2 second output on pin 3, which is used to drive the alarm circuit. I arrived at these values from the chart that came with the 555 timer. The first try gave me exactly what I wanted. I discovered, when breadboarding this circuit, that it would trigger when I pushed my mike button or flicked the switch on my desk lamp. I learned by reading my various books that the input pin 2 must be held high until the negative pulse arrives to trigger the timer. What a problem! I also needed a negative pulse every ten minutes to trigger the timer. The 7490 goes low at the end of the ten minute period and stays low until the count of eight. What a problem! At this point I needed help and found it by way of ham radio.

Another ham, Jack Sponeybarger (a retired electrical engineer), gave me the idea for the quick pulse and suggested the values that worked on the first try. This circuit uses two gates of the 7400 IC and works as follows: The 1k resistor holds pins 4 and 5 of U1B low, which in turn holds pin 6 of U1B high and keeps the triggering pin 2 of the timer high. At this time, the inputs of U1A pins 1 and 2 are either high or low, depending where the count is at any particular time. If they are low, then pin 3 of U1A is high. When pins 1 and 2 go high at the beginning of the count of eight, pin 3 goes low but nothing happens across the capacitor C6, because the other side of the capacitor is held low by the 1k resistor. Please don't get lost yet, for the real action is about to take place. When the 7490 counter reaches the end of the count of ten, its "D" output, pin 11, goes low, pins 1 and 2 of U1A go low, and pin 3 goes high, causing a brief positive spike across C6.

Now for the thrilling part of the action. This positive spike causes pins 4 and 5 of U1B to go high and pin 6 to go low, thus triggering the 555 delay timer. The only time the 555 is triggered is on the negative going edge of the output from the 7490 counter. I was quite proud of this circuit, thinking it was very original, but I later on found several versions in the *TTL Cookbook* disguised as negative or positive edge triggering circuits. There are other ways of doing this; I tried most of them, but decided to let well enough alone.

The alarm circuit is another 555 timer and is a triggerable astable multivibrator. This was stolen directly from a recent *73 Magazine* article describing a keying monitor circuit. It is almost the same, except that I

eliminated the volume control that was located ahead of the speaker and changed a few values here and there to match my junk box. The 100k pot is the tone control, which varies the tone from an ear-piercing high to an annoying growl. This is a beauty, and is the only one I have ever built from a 555 that worked properly.

Manually resetting the timer to zero was my biggest problem. This takes a bit of doing, especially when using a cheap, normally closed push-button switch. I tried every bounceless switch circuit I could find, but nothing worked 100%. Every time I went to show off my timer, I had to push the reset button a half dozen times to get it set to zero. I would get a count of one, and sometimes as high as an eight. Everything else worked nicely.

The ten minute cycle worked fine, and the alarm sounded for 2.2 seconds. The timer proceeded merrily on its way with the decimal point blinking every second as planned, but she would not reset worth a hoot. They make bounceless switches for a price, but I was determined to make this one work. Finally, I tried a circuit I copied from the *TTL Cookbook*. It consists of the other two gates of the 7400 IC and the associated goodies. This was better, but not perfect, until I added C7 to pin 8 of U1D, which gave me one failure in about ten tries.

I took the little jewel to work to show it off, and Murphy's Law set in. After a short time, the damn thing began to beep every second. I told the fellows I had designed it that way. I brought it home and started to tune up my rig. The alarm went off and it began to count like crazy. After all that work I had the only timer in the world that couldn't be used in a ham shack. My ham buddies were very helpful, making some good and some wise guy suggestions. One fellow said I shouldn't have used a wooden cabinet, so I wrapped the little dud up tight in aluminum foil – but that didn't help. It did tell me, however, that the rf was coming through the line cord. All the while, I was thinking that I could have painted my window sills this summer instead of fiddling with this thing. I was about to hide the thing in the midst of all my other failures and unfinished projects when I decided to try it in another outlet. When I unplugged it, I noticed my line cord was about 4" from my coax on the rig. When I plugged it into another outlet, it worked fine, even when I sat it on top of the rig, right over the finals.

When I reflect back on the last problem, I believe I was thinking like an engineer instead of a technician.

I still was not satisfied with the reset circuit. It was at this point in time that I added the .01 uF capacitors that I mentioned earlier. That was without a doubt the source of all my troubles. We have a computer-controlled milling machine at work, and I noticed that every IC on the circuit boards had a .01 uF from the positive input pin to ground. They were located as close as practical to the IC. I can now plug it into the outlet behind my rig, set it on top over the finals, take it to work where they have loads of line noise, and the little beauty works perfectly. I can now reset it 100 times out of 100 tries.

This miracle of modern digital electronic engineering has been running 24 hours a day since last July, counting and indicating the minutes, blinking the seconds and sounding the alarm every ten minutes. I never unplug it, except to take it somewhere to show it off. My XYL was annoyed a little for the first month or so, but then I would change the tone to another pitch to break the monotony. I guess she finally decided that as long as that thing buzzes, the OM is not working on it. ■

Have You Tried Television?

-- it's easier than you think

Ralph B. Mott WB4KTY
1816 Marion Ave.
North Augusta SC 29841

The interest in ATV is due, at least in part, to the availability of reliable 470 MHz commercial surplus gear at very reasonable prices. *73 Magazine* has had RCA transmitter strips advertised for fifteen dollars from DuPage FM, and Gregory has had GE equipment, both transmitter and receiver strips, for twelve to thirty dollars. With the advent of small compact solid state modulators (Tom O'Hara's W6ORG modulator), it has become both simple and cheap to put your ham station on ATV.

Most ATVers are members of a club, even if it only has five or six members, or they work together in groups of two or three. It ain't much fun sending a picture if nobody sees it!

Since conversions of the RCA CMU-15, GE Progress Line, and Motorola T44 have been pretty well covered elsewhere, this part of the job is no longer considered to be in the realm of mumbo-jumbo and we need not go into any detail on conversions as such. Generally, the conversion consists of building a power supply, lengthening the grid lines on the RCA, or just retuning the GE to the correct frequency. The Motorola with its 2C39s is a little different, but it still puts a potent signal on the air. We completed the first rough conversion on our new RCA CMU-15 in four evenings and a Saturday.

Neither do we plan to go into the receiver conversion. The receiver can be as complicated or as simple as you wish. We know of five guys locally who are on ATV. Four of us use RCA CMU-15s and one uses the GE Progress Line. All of us used the same general conversion information for the transmitter strips, but no two of us are going the same route on our receiver conversions. Just use your imagination. Rather than get into the particulars, we are going into customizing your gear after you have it working and putting out an acceptable picture.

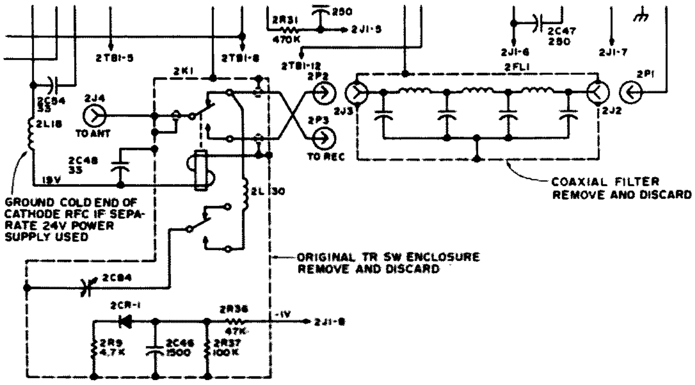

Fig. 1. Partial schematic.

Customizing your gear allows you to take a mass-produced item and convert it to your own uses. This allows your own personality quirks to come through. This thing of personalizing your equipment has become a big thing with the American male. Note the number of automobile speed and customizing shops, even such things as firearms with customized grips, cases, and holsters, or do-it-yourself home remodeling, built-ins, and add-a-room projects. These are all fair game for the avid do-it-yourselfer, so why not your ATV rig?

There are not many appliance operators among the ranks of the ATV fraternity. Until recently, there was just no commercially made ATV available, so anyone on ATV had to be a home brewer. In getting my ATV station on the air, I had a lot of fun and learned a good deal about UHF as well. We now have really effective PTT type operation, and this makes for a lot of fun and satisfaction.

My ATV station is not the quick and easy type. We had been active on ATV for some time when we got tired of throwing two or three switches and waiting for the video to come on, so we decided to make further refinements. We had removed the coaxial filter between the antenna PI tuning section and the antenna switching relay. In this unit the antenna switching relay coil is in the cathode circuit of the 5894 second tripler-driver stage. There is 19 volts available at this point, used to control the TR relay. When excitation and B+ is applied, the second tripler-driver conducts, causing the relay to switch the antenna. The B+ is applied through a relay on the power supply strip on the original chassis. We had considered using the original TR switch; however, when we removed the coaxial filter to

broaden out the bandpass, we were left with about fourteen inches of open space to fill between the output PI section and the TR switch. The TR switch was located on the front of the chassis. After some thoughtful moments, we decided to leave the short four inch piece of coax undisturbed due to the way it was attached to the antenna matching assembly enclosure. Also, this area is rather crowded, and all space saving ideas must be utilized, including mounting the modulator circuit board on the underside of the chassis. Since the original TR switch must be shielded if it is to be used, there just was not enough room for all that had to fit there.

We found that an old TR switch out of a junked ARC-3 would work as well as the original. Mounting it directly on the rear panel within three inches of the PI network output allowed us to solder directly to the cable which was already there. We completely removed and discarded the original TR switch along with the components in the box with the relay. This included the 1N48 diode and the 48k and 100k resistors, which we soon discovered was where the rf came from which was available at pin 8 on the 11 pin metering socket on the top of the chassis. We now use an rf loop coupled directly to the antenna coax line for an rf indicator. This works very well and gives a true indication of the rf power level if properly calibrated. It can also be used to check swr by reversing the leads in the line.

If the ARC-3 arrangement does not appeal to you and you have a 24 volt transformer and relay knocking around the shack, it would work just as well to build up a small power supply for the TR switch. We made everything in the rig straight PTT and mounted our 24 volt relay directly on the chassis of the power supply. We prefer 24 volt control circuitry to 110 volt control for obvious reasons. Holding 110 volts in your hand on a PTT button does not seem to be the best way to go. For those brave souls using 110 volt control, the extra trouble of the 24 volt supply can be eliminated.

Using 19 volts available at the relay end of the RFC in the cathode line saves running another line from the power supply to the transmitter chassis. If it is desired to use an external 24 volt source to operate the TR switch, the cold end of the RFC in the cathode circuit must be grounded, because the coil of the original TR relay was part of the cathode resistance in the 5894.

To mount the new ARC-3 TR switch, drill two 5/8" holes on 2½" centers, remove the RCA plug from the end of the coax cable, and solder the coax directly to the input of the new TR switch. Then retune and you are in business.

One word of caution: When we were originally converting our CMU-15, we had some circuitry underneath the rf cage bottom plate. After a while, a short developed which completely killed the signal. The rig would work with the bottom of the rf cage removed, but not when it was in place. We found that one of the screws holding the bottom plate in place extended through the plate far enough to short one of the grid lines. When we removed the screw and plugged the hole, we had no more trouble.

The small size and potent 15 Watt signal make the CMU-15 a natural for mobile or portable operation, making possible good on-site displays at hamfests and meetings. As soon as the power supply has been completed, we are looking forward to an ATV session with an aircraft mobile. Should be fun! ■

Quick Vertical

- - for 20 and 40

Verticals have always performed well on the long haul DX contacts that many hams enjoy participating in. The vertical radiates power at a very low angle, enhancing the possibility of a DX contact. The dipole radiates power at a much higher angle.

The antenna I am going to describe was designed for simplicity. It is simple to erect, taking a matter of an hour or so, and will not make a dent in your wallet!

The radiating portion of the antenna is made of #18 wire. Many other sizes may also be used. Cut the wire to a length of 28 feet. The wire may then be held up in a number of ways. A well-used scheme has been to run the wire up a wooden pole.

Once the wire is held up vertically, you can proceed to hook up the feedline. The feedline used is *ordinary speaker wire*, commonly sold at Radio Shack stores. It just so happens that the speaker wire has an impedance of approximately 45 Ohms, and works beautifully as a balanced feeder. Hook up one side of the line to the base (the wire) of the vertical, and the other wire to a ground rod, at least 5 feet long. It is also advisable to have 4 or more ground radials each 33 feet in length connected to the ground rod.

After the feedline has been brought into the shack, it will have to be trimmed to a length that will reflect the least amount of current, as the antenna does not resonate exactly on the 20 and 40 meter bands. A bit of juggling with the length of the antenna feedline will give you a respectable match. If you start by tuning the antenna up on the 40 meter band, the 20 meter band will also have a low swr with the same length of feedline.

This antenna works well on both 20 and 40 meters, with an swr of 1.3:1 on both bands. The antenna is quite broadbanded; it is possible to operate both CW and SSB on both bands. After putting up this antenna, the first station I worked was a Russian. Although this antenna works well as a regular home-QTH antenna, it is especially suited for portable operation and use, due to its ease of construction and erection. ■

Try
Power Saver Logic

- - a guide to CMOS applications

Appearing for the first time commercially in 1968, complementary metal oxide silicon (CMOS) logic elements have been steadily advancing and are presently competing strongly with other logic families. These devices are monolithic integrated circuits containing P-channel and N-channel enhancement type MOS field effect transistors. The MOSFETs exhibit high input impedance (requiring very low input driving currents) and can operate over a wide range of supply voltages (3 to 15 volts). Also, the complementary arrangement of the two output transistors prevents both from being turned on simultaneously. As a result, there is no direct path for dc current flow and consequently power drain is very low.

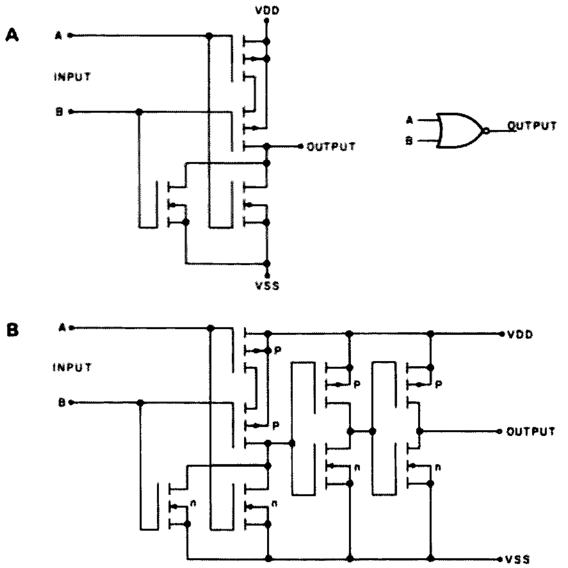

Fig. 1. Diagram showing (a) a conventional 2-input NOR gate and (b) a fully buffered 2-input NOR gate.

CMOS devices also exhibit an almost ideal logic transfer characteristic, meaning that they have exceptionally high noise immunity. As an example, CMOS logic elements have a guaranteed noise margin of about 1.5 volts, while other logic elements (such as TTL) have noise margins of only 0.4 volts.

These main features – the low power consumption, operation over a wide range of supply voltages, and high noise immunity – make CMOS logic easy to work with. However, like other logic families, certain design rules must be followed if successful results are to be obtained. In many cases, the design rules are different from past practices with TTL logic, and these differences will be discussed in greater detail in subsequent sections.

The technology is also improving as more and more manufacturers compete to produce smaller, lower priced chips containing more complex circuits. There is presently a large assortment of medium and large scale integrated circuits to choose from in building communication systems, instruments, and computer interfaces, including microprocessor applications. In addition, you may choose from standard non-buffered logic, or the "B" series of fully buffered gates. Fig. 1 contains a typical diagram of both a conventional NOR gate and a fully buffered NOR gate. The input gate protection circuits, not shown in this figure, will be discussed later.

While there are some differences among the various manufacturers concerning specifications, there are certain definitions that all generally agree on. These basic parameters along with their symbols and definitions are shown in Fig. 2. In working with CMOS circuits, you should become familiar with the various parameters contained in this chart to avoid exceeding the power limitations of the devices and also as an aid in debugging new systems.

CMOS CHARACTERISTICS AND FEATURES

The CMOS family is unique in that it contains many of the same functions found in TTL, while also providing special functions not available in any other logic family. The following is a partial listing of some of the functions available:

1. NOR gates (2, 3, 4, and 8 input)
2. AND gates (2, 3, and 4 input)
3. OR gates (2, 3, and 4 input)
4. NAND gates (2, 3, 4, and 8 input)
5. Inverters and Buffers
6. Complex gates

(exclusive OR, NOR, etc.)
7. Flip-flops (R-S, D, J-K, Tri-State)
8. Counters (BCD, Binary, Decade, Up/Down)
9. Registers
10. Decoders/Demultiplexers
11. Decoder/Drivers
12. Analog Switches

The analog switches are unique and have no TTL equivalent. In addition, there are hex contact bounce eliminators (MC14490), watch/clock circuits (MC14440), oscillator/dividers (MC14450), and tone encoders such as the MC14410.

PARAMETER	SYMBOL	DEFINITION
Input Current	I_{in}	The amount of current flowing into the device at a particular voltage on the input terminal and also a specified V_{DD}.
Input High Voltage	V_{IH}	The range of input voltages that represent high logic level.
Input Low Voltage	V_{IL}	The range of input voltages that represent a low logic level.
Minimum Input High Voltage	V_{IH}(MIN)	Minimum input high level allowed.
Maximum Input Low Level	V_{IL}(MAX)	The maximum low level input logic allowed.
Output High Current	I_{OH}	The amount of drive current flowing out of the device at a logic high level output voltage and V_{DD}.
Output Low Current	I_{OL}	Drive current flowing into the device at a logic low level output voltage and V_{DD}.
Quiescent Power Supply Current	I_{DD}	Current flowing into the drain terminal.
Source Voltage	V_{SS}	Positive potential on the device.
Drain Voltage	V_{DD}	Negative or reference power supply (usually ground potential).
Output High Voltage	V_{OH}	Output voltage for a high level logic.
Output Low Voltage	V_{DL}	Output voltage for a low level logic.

Fig. 2. Parameters, symbols, and definitions for CMOS devices.

Comparison to TTL

In general, CMOS specifications are a bit loose when compared to the rigid parameters of TTL logic. Industrywide, there are variations between devices of different manufacturers, as well as variations between devices produced by the same supplier. However, being aware of these differences should be sufficient for you to overcome any problem areas that may arise. Also, it's important to realize that many parameters such as current, voltage, and ac characteristics are standard for all devices.

As mentioned previously, the primary advantages of CMOS over TTL include low power dissipation, low quiescent current, high noise immunity, high fan-out, and reliable operation over a wide range of supply voltages. These features are summarized in Fig. 3 and will be discussed in greater detail throughout this article.

Quiescent Current and Power Dissipation

In order to understand the low power operation of CMOS devices, let's review the circuit structure of a typical inverter stage. Fig. 4 shows a basic CMOS inverter including input protection circuitry.

In the quiescent state, one output transistor is off while the other is on. For this reason, the only direct path for dc current flow is leakage through the input protection diodes. This current flow is small and is on the order of 1 nanoamp.

Only when the device changes state does any significant current flow occur, and this is due mainly to the charging and discharging of internal and external capacitances. Once these capacitances are fully charged, current flow ceases again. Therefore, most of the power consumption occurs at short intervals during the transition of one logic state to another.

Power dissipation in CMOS devices is therefore directly proportional to the supply voltage, frequency, output load (capacitance), and one other factor – the rise time of the input signal. This relationship is summarized in Fig. 5.

To determine why capacitance plays such an important part in power drain, we must look to the input characteristics of the devices. Since the input stage of one device is usually the output load of the preceding device, the two are usually interrelated. The input of all CMOS gates may be represented as a resistor with a value of 10^{12} Ohms in parallel with a 5 pF capacitor. As CMOS devices are added in parallel, the total capacitance increases as the sum of the capacitances of the individual gates. For this reason,

PARAMETER	STANDARD TTL	LOW POWER TTL	CMOS (5 Volt)	CMOS (10 Volt)
Quiescent Power (per gate)	10 mW	1 mW	5 nW	10 nW
Power Dissipation (per gate)	80 mW	18 mW	5 mW	20 mW
Noise Immunity	1 Volt	1 Volt	2 Volts	4 Volts
Toggle Frequency	35 MHz	3 MHz	5 MHz	10 MHz
Propagation Delay	10 nsec	33 nsec	60 nsec	25 nsec
Input Current	1.6 mA	0.18 mA	±10 pA	±10 pA
Fan-Out	10-STD TTL or 40-74L	10-74L	50*	50*
Input Impedance	5000 Ω	50,000 Ω	10^{12} Ohms	10^{12} Ohms
Output Impedance	100 Ω	10 Ω	400 Ω	200 Ω

*Depends on propagation delays.

Fig. 3. Comparison of standard TTL, low power TTL, and CMOS devices.

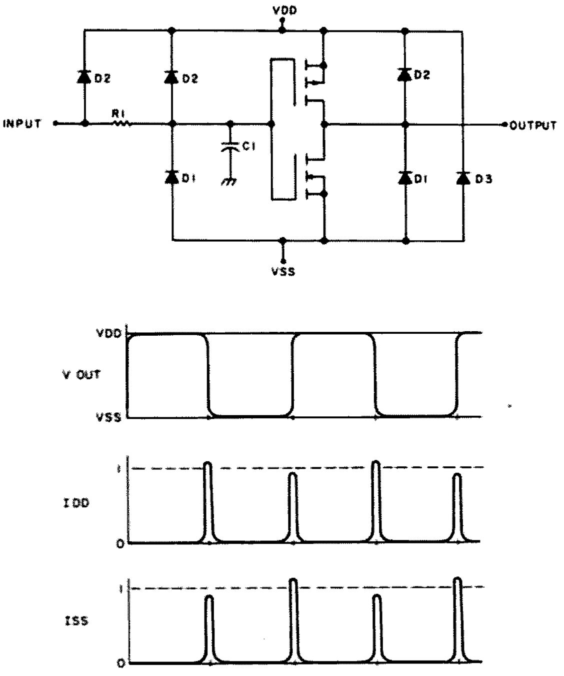

Fig. 4. Basic CMOS inverter with input protection. C1 — 5 pF; R1 — 200Ω; D1 — 25 V; D2 — 50 V; D3 — 25 V; Input: $t_r = t_f \cong 10\ \mu sec$; Output: $C_L = 15\ pF$.

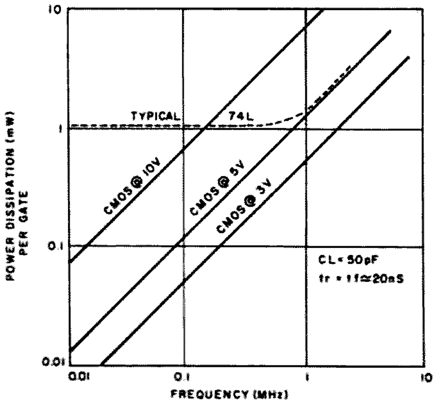

Fig. 5. Power dissipation as a function of the operating frequency.

the propagation delays and capacitance load (not the input driving load) are the factors that ultimately determine the fan-out limits of the device.

Input Current, Gate Protection, and Noise Immunity

As mentioned previously, the input impedance of CMOS devices is extremely high. Consequently, very little driving current is required for the device to change its state, or switch. Typically, the input current is ±10 pA. This low input current requirement is the reason that fan-out for the CMOS family approaches 50 (limited by the propagation delay), compared to TTL with a fan-out of only 10 gates. However, in most applications, the propagation delays will usually limit fan-out to 20 gates or less. There seems to be some discrepancy here, since many manufacturers specify propagation delays at 5 V or 10 V, 20 nsec transition, and a 15 pF load. The problem area is the 15 pF load, which seems to be standard among other logic families. For CMOS, it is somewhat unrealistic and a 50 pF load is closer to actual conditions. Most manufacturers are now beginning to specify propagation delays at output loads of 50 pF; this should help to clarify the situation.

Another CMOS characteristic that requires careful attention is its input impedance. While high input impedance is a distinct advantage in most circuit applications, it can also present problems wherever static electric charges are present. In an effort to protect the input gates, each manufacturer has incorporated some form of diode protection arrangement along with a series resistor to limit current flow. A typical example of this is shown in Fig. 6.

However, extremely high voltages generated during very low humidity conditions will still damage the gates. Because of this, certain handling precautions should be observed which include:

Gounding of all test equipment, tools and soldering irons;
Storing CMOS devices in conductive foam or tubes (never in polystyrene foam); and
Never insert or remove devices with power applied.

Noise immunity is another parameter used to specify logic elements, and one form of noise is related to the speed of the device. Since TTL logic is faster than CMOS, the TTL device will transmit noise while the CMOS device rejects it. This is true for pulses of short duration as well as high frequency oscillations. This characteristic is often referred to as the "ac noise immunity," and it increases as the input pulse width becomes less than the propagation delay of the device.

Another consideration is "dc noise immunity." Due to the complementary action of the CMOS inverter (one transistor on while the other is off), the switching point is midway between the logical 1 and logical 0 states, or 45%-55% of the dc supply voltage. This results in a high dc noise immunity that increases with the supply voltage. This feature is illustrated in Fig. 7 for both buffered and unbuffered CMOS, as well as TTL characteristics.

A discussion of noise immunity would not be complete without mentioning external noise. The higher output impedances (10 to 100 times higher than TTL) exhibited by CMOS devices make them more susceptible to extraneous noise and cross-talk. Capacitively coupled noise immunity is one area where TTL is superior, although CMOS is hard to beat in terms of dc noise margin. Also, good printed circuit board layout practices will overcome any capacitive-coupled noise problems related to CMOS circuit design.

POWER SOURCE RULES

The overall costs of CMOS systems may be lower than equivalent TTL designs due to the lower power dissipation of CMOS devices and their ability to operate reliably over a wide range of supply voltages. Simple low

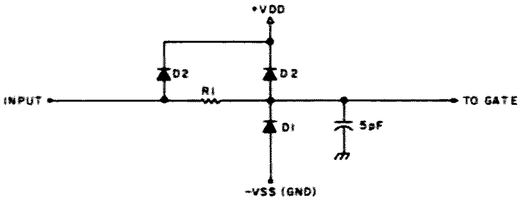

Fig. 6. Typical input gate protection circuit. R1 ≅ 200 to 2000Ω; D1 = 25 volt diode; D2 = 50 volt diode.

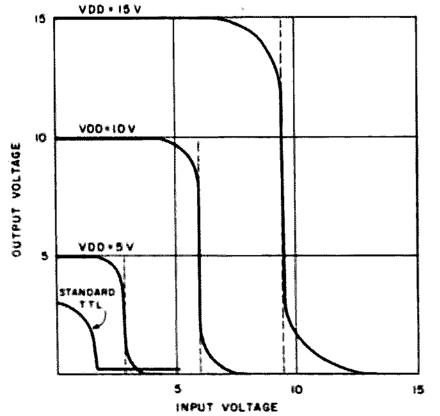

Fig. 7. Noise immunity increases with the power supply voltage as shown by these logic transfer curves.

cost power supplies with a minimum of regulation are all that is required to make the CMOS system operational.

From the comparison to TTL in the previous section, we learned that CMOS devices consume less power than standard TTL by a factor of 10^6. As an example of what this means, consider a system of 20 CMOS packages operated from a 5 volt power supply. At low frequencies, the total current drain from the power supply will be only 1.2 mA for all 20 devices! It is evident from this example that all portable battery-operated electronic systems should incorporate CMOS devices for low power consumption and long battery life.

Absolute Maximum Ratings

As with all electronic components, there are operating range limitations which, if exceeded, will destroy the devices. The maximum ratings are summarized in Fig. 8 for both the "A" series and "B" series devices. Maximum V_{DD} is +15 volts for the "A" and +18 volts for the "B" series. Maximum power dissipation is 200 mW and the maximum operating temperature for ceramic packages is +125° C and +85° C for plastic packages.

Typical Supply Voltages

All CMOS devices will operate reliably with V_{DD} in the range of +3 volts to +15 volts (with V_{SS} at ground potential). For this reason, CMOS is ideal in auto electrical systems, battery-operated instruments, and numerous other applications.

It is necessary to keep in mind, however, that the speed of operation is directly proportional to the supply voltage. Referring back to Fig. 3 in the previous section, at +5 volts, the maximum toggle frequency is 5 MHz, while at 10 volts, it increases to 10 MHz. Also, as the supply voltage increases, so does the power consumption. It is sometimes necessary to compromise between the desired operational frequency and the power consumption of the system at that frequency.

Power Supply Circuits

Almost any power supply will perform satisfactorily in a CMOS system because precise voltage regulation is not a primary consideration. However, it is necessary to keep the supply voltage within the 3 to 15 volt range and suppress any transients that may exceed the 15 volt range. An example of a typical power supply is shown in Fig. 9.

As mentioned previously, CMOS devices are ideal for operation from battery power supplies. Since the supply voltage is not critical, inexpensive dry cells may be used which exhibit large voltage drops as they reach the end of their useful life cycle. As an example of a standby battery system, Fig. 10 shows a rechargeable battery system added to the ac power supply just described.

There are a few power source rules that should be followed when working with CMOS systems. Careful observance of these rules will save you much time and frustration, not to mention reducing the failure rate of the CMOS devices.

Rule 1: Do not apply input signals to CMOS inputs without first supplying power to the V_{DD} and V_{SS} terminals of the device.

Rule 2: Always keep the operating supply voltage for V_{DD} within the 3 to 15 volt range (+18 volts for the "B" series).

Rule 3: Reversing the power supply polarity will permanently damage CMOS devices.

Rule 4: For operation of CMOS buffers from split voltage power supplies, V_{DD} should always be equal to or greater than V_{CC}.

Rule 5: For safe operation, limit the power source current to as low a value as practical for the system.

Rule 6: Transient turn-on of the input protection diodes may result from voltage drops across large resistors in series with V_{SS} or V_{DD}. Such resistors should be avoided wherever possible.

INPUT DESIGN RULES

Due to the high input impedance of CMOS devices, certain design rules should be followed to protect the gates. These rules, including TTL interface and handling considerations, are summarized as follows:

Rule 1: *Unused Inputs Must Be Connected to V_{SS} or V_{DD}.* If this rule is not followed, the device may generate faulty logic or exceed its rated power dissipation. Some manufacturers, in the case of plug-in type circuit boards, recommend that all inputs have some type of shunt resistor (200k to 1 megohm) to either V_{SS} or V_{DD}, whichever is appropriate for the specific logic circuit. This will serve to protect the IC when the board is not plugged into the main frame, or during storage when static charges may exceed the internal protective circuits.

Rule 2: *Input Signals Must Not Exceed the Power Supply Voltage Range of V_{SS} and V_{DD}.* Under certain conditions, however, the gate protection diodes will also conduct during normal operation and attempt to exceed the maximum input current of 10 mA. When these conditions exist, such as in oscillator applications, a series input resistor should be installed to limit the input current to a safe value. Typical series resistor values range from 10 kilohms to 100 kilohms without affecting the electrical characteristics, although the speed is reduced

PARAMETER	SYMBOL	"A" SERIES	"B" SERIES
Maximum Supply Voltage	V_{DD} (+) V_{SS} (-)	-0.5 to +15 V dc	-0.5 to +18 V dc
Maximum Input Voltage	V_I	$V_{SS} \leq V_I \leq V_{DD}$	$V_{SS} \leq V_I \leq V_{DD}$
Power Dissipation (per package)	P_D	200 mW	200 mW
Maximum Temp. Range (PLASTIC)	T	-40°C to +85°C	-40°C to +85°C

Fig. 8. Absolute maximum ratings for CMOS devices.

Fig. 9. Ac power supply for CMOS systems (10 V dc @ 50 mA). C1, C2 — 100 uF @ 35 V dc; D1-D4 — 1N4001; D5 — 10 V zener @ 1.5 W; R1 — 82Ω, ½ W.

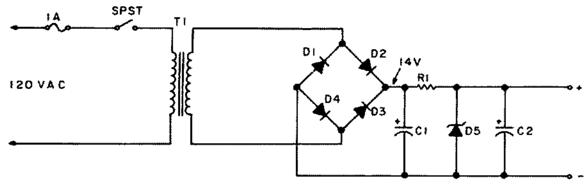

Fig. 10. Standby battery system. R1 is chosen to limit the trickle charging current to the battery during ac operation. When the ac power fails, D2 conducts, while D1 blocks the battery current to the transformer supply, and the battery powers the system.

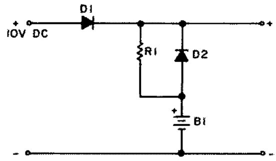

inversely with the increase in RC delay.

Rule 2 may be interpreted to mean that no input signals may be applied if the power supply is accidentally disconnected or turned off. However, if the proper series resistor is installed in the input circuit to limit the input current to 10 mA, the device will not be damaged under these conditions.

Also, for extremely hostile environments, you may want to consider installing external protective diodes to limit input voltage levels.

Rule 3: When a CMOS Device is Driven by a TTL Device, a Pull-Up Resistor is Required from the CMOS Input to +5 Volts for Open Collector TTL. The value of this pull-up resistor is usually a compromise between speed and power consumption. Typical values range between 1000 Ohms and 10 kilohms, with 2 kilohms providing the best trade-off between speed and power. Fig. 11 shows the relationship between the pull-up resistance and its effects on propagation delay.

Devices with internal pull-up resistors present no problem in driving CMOS devices as long as all devices are operated at +5 volts. In some cases, an external pull-up resistor may be required to insure reliable operation in the high state.

In the case of a CMOS device driving TTL logic, it's best to use a buffer such as the CD4049 or CD4050 operated with the 5 volt TTL power supply. These buffers are rated to drive two TTL loads at 5 volts. Also, unlike the CD4009 and CD4010 that require two power supplies, the 4049/4050 will operate satisfactorily from one power source.

OUTPUT DESIGN RULES

The output voltage levels for CMOS devices depend significantly on the level of V_{DD}. For example, for the CD4001A quad two-input NOR gate @ 25°C, the high level output voltage, V_{OH}, is 4.99 volts minimum for V_{DD} = 5 volts. When the supply voltage is 10 volts, V_{OH} = 9.99 volts minimum, and for all practical purposes, V_{OH} follows the value of the supply voltage.

The low level output voltage is typically zero or equal to V_{SS}. Compared to TTL logic, this is significant voltage swing, which accounts for the high noise immunity of CMOS devices. This V_{DD} to V_{SS} voltage swing is typical for all CMOS devices.

The output drive current (sink current) I_{OL} @ V_{OL} = 0.4 volts is dependent on the type device. For example, a plastic CD4001A will sink 0.3 mA and a CD4009A buffer will exhibit an I_{OL} = 3 mA. These are typical values with slight variations among the different manufacturers.

A few of the output rules and characteristics of CMOS devices are as follows:

Rule 1: CMOS Devices Have a Typical Fan-Out Capability of 50. Since the input current I_I is typically 10 pA, it becomes obvious that CMOS devices with output drive currents of 0.3 mA (3 mA for buffers) are capable of driving many gates. However, due to the high input impedance (10^{12} Ohms), a CMOS driver sees the gate as a capacitor. As more gates are added in parallel, the propagation delays increase due to the increase in capacitance, and the next result is that speed is reduced as the fan-out increases. In this case, the limiting factor is not drive current, but capacitive reactance! Perhaps a more realistic fan-out would be in the neighborhood of 20 gates or less.

Rule 2: Do Not Short a CMOS Output to a Power Supply Bus Greater Than 5 Volts. CMOS devices are not short circuit protected and consequently, for shorts *above* 5 volts, the maximum power dissipation of the device will be exceeded. For operation at 5 volts or less, it is possible that the device may withstand an output short, although this may vary with the device.

Rule 3: CMOS, As With Open Collector TTL Logic, Cannot Be "OR" Wired. The reason for this design rule is to prevent an "ON" P-MOS and an "ON" N-MOS transistor from being shorted directly across the power supply terminals. One solution to this problem is to use tri-state logic wherever practical.

Rule 4: The Paralleling of Inputs and Outputs of Gates is Recommended Only When the Gates Are Within the Same Package. Due to the variations in specifications between the devices, in addition to the non-standardization of devices from the same manufacturer, problems may be avoided by paralleling of inputs and outputs only within the same package. The reason for this is to maintain a proper match and coordinate the various parameters involved.

Rule 5: Output Loads Should Be Returned to a Voltage Source Within the Range of V_{DD} to V_{SS}. Here again, an attempt is made to limit the power dissipation of the device. Also, since output logic levels are directly related to V_{SS} and V_{DD}, returning the load to a voltage higher than the power supply may exceed the maximum voltage rating of the device.

Rule 6: Avoid Large Capacitances (5000 pF or Greater) on the Outputs of CMOS Buffers or High Cur-

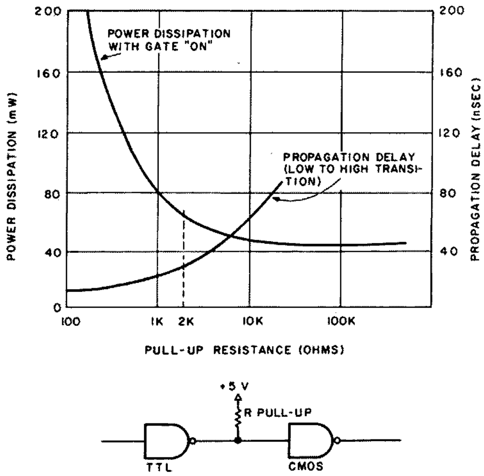

Fig. 11. Typical speed/power relationship for TTL interface with CMOS logic. The open collector TTL gate requires a pull-up resistor.

rent Drivers. Capacitances of this magnitude act as short circuits and may overheat the output transistors.

Rule 7: A CMOS Buffer Will Overheat If Used as a Linear Amplifier. CMOS devices draw maximum current during the transition of states. If these devices are made to operate linearly, current will be drawn for a longer period of time and the device will overheat. This is the reason that maximum clock rise and fall times (usually 5 to 15 secs) are specified for CMOS devices. Longer rise and fall times for devices operated over 5 volts will result in exceeding the maximum power dissipation of the device.

CONCLUSION

Each manufacturer of CMOS devices identifies his device with a distinct part number in which the basic function type can be picked out. For example, the following is a partial list of CMOS manufacturers and their own characteristic device number:

	Type Number
RCA	– CD ----
Motorola	– MC1----
National	– CD ----
Fairchild	– F ----
Harris	– HD ----
TI	– TP ----
Signetics	– ---- (no prefix)

For RCA devices, the suffix letter immediately following the four digit function code usually indicates conventional ("A") or fully buffered ("B") configuration. The second suffix letter indicates the type of package, "E" for dual-in-line plastic, "F" for dual-in-line ceramic, and "K" for the flat pack ceramic. As an example, the CD4001AE is a quad 2-input NOR gate, unbuffered, in a dual-in-line plastic package. ■

HF Bands Expander!

-- eliminate splatter to gain operating room

With many of the speech processing circuits in vogue these days, the SSB operator often operates his rig on the thin line between keeping it fully modulated and overmodulation with its attendant splatter. There are very few devices which can respond instantaneously to the changes in PEP as a transmitter is modulated and so inform the operator when a PEP value has been exceeded, which causes the transmitter to flat-top and splatter. Meters, no matter where they are located in the transmitter or antenna chain, are useless to identify transistory modulation peaks unless they are equipped with somewhat elaborate peak sensing and storage circuits. The only devices which by themselves can respond essentially instantly to voltage/current changes are electron tube display devices (scopes and magic-eye tubes), neon bulbs, and LEDs.

An oscilloscope is, of course, one of the best monitoring devices one can use. But, a scope can be expensive to employ as just a monitoring device, and it is not always easy to hook up a regular bench type scope for modulation monitoring. Also, it is hardly a handy monitoring device for portable operation. This article explores the use of simple and inexpensive neon bulbs and LEDs for the instantaneous indication of different PEP output levels.

The idea of using neon bulbs as an inexpensive PEP output indicator is certainly not new. It was done by many amateurs in the early 1960's, but it often proved to be a problem to get reliable indications on various bands unless the bulb circuitry was located at some point in the transmitter output line where the impedance remained the same on various bands. Today, this is not so much of a problem, since almost all amateurs use coax and also use a transmatch or similar device along with an swr meter between their transmitter and the antenna transmission line. The coax from the transmitter to transmatch is "flat" on every band, and that is the point at which to locate the PEP indicator.

W6GWS came up years ago with the circuit shown in Fig. 1(a). It is simply two neon bulbs connected in series with the voltage dropping resistors arranged so one bulb lights at a chosen *normal* modulation level and the other bulb lights when a *chosen PEP limit* is reached. The circuit can be used across any impedance transmission line. The *total* value of the resistances needed is calculated using Ohm's law, knowing the approximate transmitter power output, the impedance of the transmission line, and using a figure of 1 Watt for the power consumed in the bulb circuitry. The values of R1 and R4 will be 1k or more for any transmitter output of 100 Watts or more, so these resistors, which should be a fixed carbon type, isolate the circuitry from the transmission line so no loading effects are noticed. The resistor directly across the bulbs can be any sort of carbon trimmer pot or regular carbon pot rated at 1 Watt or more.

The ideal way to adjust the ignition point of the bulbs initially is with a monitoring scope. Adjust R2 so the bulb associated with it lights fully when a normal modulation level is achieved with no flat-topping. Adjust R3 so its bulb just starts to glow when flat-topping just occurs. The adjustments may interact a bit, so one has to go back and forth a few times to check the settings. An alternative to the scope method is to insert a carrier so the transmitter draws 80-90% of its normal dc input. Then adjust R2 to light its bulb. Further, reinsert the carrier for the full dc input and adjust R3 so its bulb ignites. The latter ignition point should be checked by some on-the-air checks, if possible, to ensure that it warns when overmodulation starts to cause splatter.

The circuit of Fig. 1(a) works best with linears having about 150 Watts or more PEP output. For PEP output levels of down to 60-70 Watts, the simple circuit of Fig. 1(b) is used. It also uses a NE-17 neon which ignites at a slightly lower voltage (55 volts) than the usual NE-2 (65 volts) and has a larger glow surface. As before, one bulb is set to indicate normal modulation and the other to indicate the danger of flat-topping. 1k isolating resistors are used and the variable resistor calculated on the basis of the

voltage across the line (calculated on the basis of the line impedance and the PEP output) and the fact that the neons use about ¼ Watt of power.

A point to watch when using either neon circuit is that the variable resistors will set the ignition point of the neons, but the extinguishing voltage depends on the characteristics of the neon bulbs. Before finalizing a circuit, check that the extinguishing voltage of the neon used for flat-top warning is the higher of the two particular bulbs used. Otherwise, one can get a slightly confusing indication where the flat-top bulb, once a peak ignites it and the normal modulation bulb, will remain glowing for an instant after even the normal modulation bulb extinguishes.

LEDs can be used instead of neons and present both advantages and disadvantages. The disadvantages are the size of the indicators and that LEDs do not have quite such a distinct or sharp turn-on point as many neons. But, LEDs draw less power and can be used down to quite low power levels. By using a green LED for normal modulation and a red LED for flat-top warning, an interesting display can be created.

The LEDs, being dc devices, require a rectifier circuit as shown in Fig. 1(c). The approximate total value of the variable resistor needed can be calculated on the same basis as before, except that the typical LED will require about .03 Watts for operation (1.5 volts at 20 mA).

Whatever circuit is chosen, it must be properly shielded since one is tapping into the transmitter transmission line. The circuitry required is so small that in many cases the circuitry can be enclosed within a transmitter, an swr bridge, or an antenna matching device. In the case of the LEDs only, they can be remotely located once the sampled rf signal is rectified. So, the rectifier circuitry could be located by the antenna terminal of a transmitter and the LEDs on the front panel. An alternative is to use a small minibox enclosure which has a coax receptacle and use a standard T connector to break into the transmission line.■

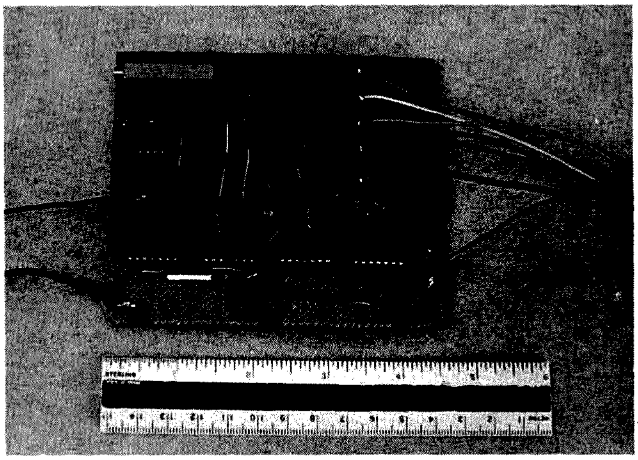
Fight Inflation! Build It Yourself!

-- tips on planning construction projects

Photos by Ira Joffe WA3PTC.



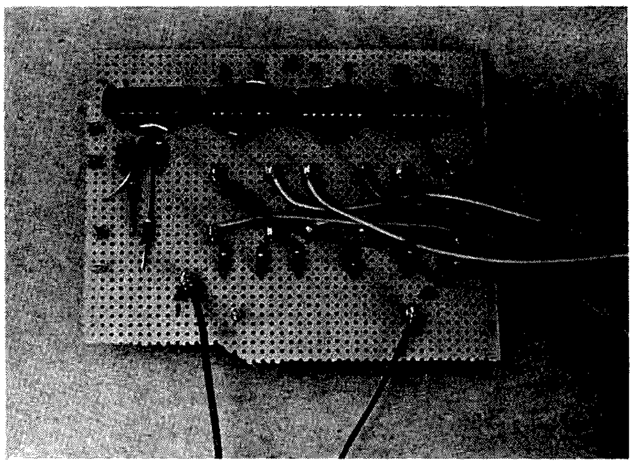
Board which includes timing generator. Trimpot in lower right hand corner is set to 90 Hz for 60 words per minute RTTY machine.

One of the lesser mysteries of hamdom is what makes one ham an operator and another a builder. At one time I monitored an active repeater, trying to sort out from the conversations who might be the operators and who might be the builders. Subsequent eyeball contacts did not confirm my deductions.

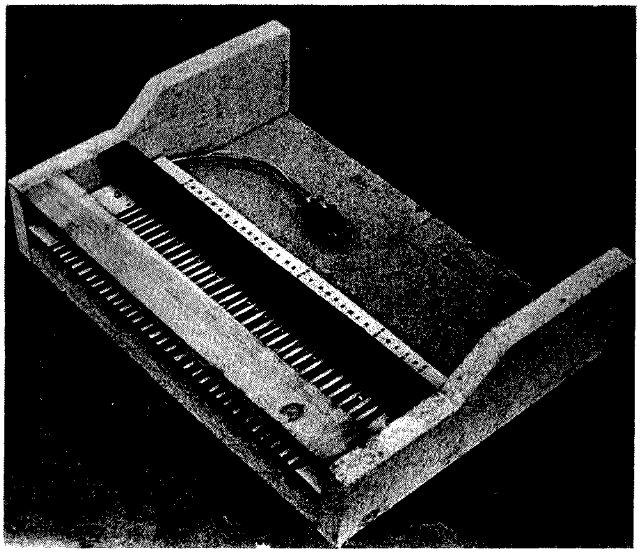
The builders were randomly distributed among the talkers, so the next question was, "Why are there not more builders on the scene?" Certainly there is the small parts shortage, for transmitter projects in particular. There also exists the "mail order lag," which can be discouraging, and finally there is to some degree the "stone wall of solid state." This exists to a degree amongst those of us who cut our teeth on vacuum tubes and still think of the collector as the plate (this includes me).

There is certainly no dearth of good construction articles, particularly in *73*, for both the beginner and the old-timer, although I must admit that if I were starting a ham career today, I might be a bit hard put to tackle some of the most interesting construction articles. With this little bit of soul searching out of the way, I decided to examine closely my mode of attack when I found a construction article of interest.

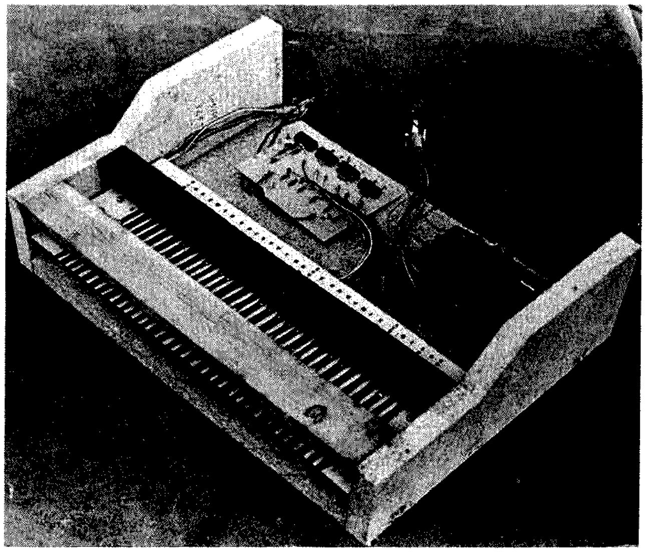
The March, 1976, issue of *73* carried an excellent article by Louis Hutton K7YZZ (page 76) entitled "Build this Exciting New TVT." My basic interest was in Part One, which described an electronic



Memory board.



Basic shell with matrix laid in to show position.



Basic shell with all three electronics packages roughly placed.

keyboard that would run the RTTY printer with which I had been gifted.

What decided me to build the keyboard unit was need, plus the fact that anything with so large an object as a keyboard attached did not have to be micro. This is a large consideration to us who are of bifocal bearing age.

In any multi IC project, there is always this decision: Should you make it up on one big board or separate the circuit into logical chunks that can then be connected together? I always stay away from the "big chunk" theory and try to make the small boards plug together with connectors for ease of troubleshooting.

Most projects somewhere along the line will display the personal foibles and beliefs of first the originator and then the duplicator. Lou had formatted his clock oscillator using a 7400 NAND gate with 2.2 uF capacitors as part of the frequency determining elements. I have a personal hang-up about using such capacitors if there is a way to use a more stable animal such as a mylar or polystyrene unit. I also happen to like the 555 chip for purposes of this kind. Fig. 1 shows the original oscillator and my final version. I further added to the detour from the original article by not adding the switch selected keyboard speed arrangement.

The same capacitor hang-up made me change the configuration of his reset generator. I used the same chip, a 74121 single shot multivibrator, but changed the configuration slightly to avoid use of electrolytics to determine the pulse output. Everything that I have read leads me to believe that this was a reasonable change for the better. Fig. 2 shows the original circuit and my modification.

Lou's article also showed an end of the line counter, which is a great convenience. I omitted this, as I had rigged up a micro switch actuated by carriage movement which dings a bell at me when the last five spaces on a line come into view.

These compromises and adjustments gave me the contents of my first board, namely a 555 for the clock oscillator, two 7473 flip-flop packages, the 74121 single shot, the 74151 data selector chip, and one 7400 NAND gate package. This total of six chips was put on a 4 inch by 5 inch piece of perfboard.

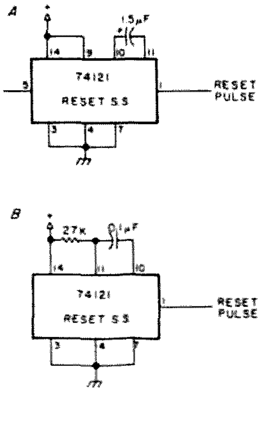
Fig. 2. (a) Original reset generator circuit. (b) Author's revised circuit.



The companion board merely had four 7400 NAND gate packages on it, these serving as basic memory capacity and letters/figures indicator control functions.

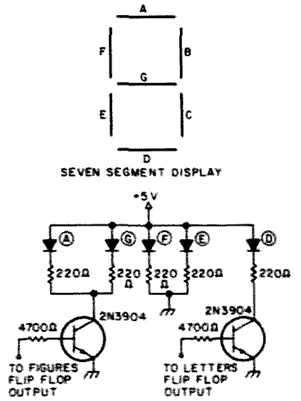
Now we have cut the project down to size by some analysis, elimination, and expression of our personal tastes and opinions. Perhaps if this exercise in technical democracy was practiced more often, those of you who now hesitate to build might do so more frequently.

The single large piece of electrical work left was to create the diode matrix which forms the various character combinations. Again, since the finished product is going to be about the size of a portable typewriter (without encountering scorn), there was no reason to go micro in any way with the matrix. A piece of circuit board 5 inches by 13 inches (copper on one side) was coated with resist. Some 32 circuit stripes were cut into the board running parallel to the five inch dimension. You only need 31 of these stripes, but I always give a bit extra just in case something goes wrong in the etching or the drilling. This is not chicken, but very practical, as disenchantment with one's own etched boards can also turn off the would-be builder.

A finely laid out, closely spaced PC board can give you fits, but an item like this matrix board is just so macro that it can't be a stumbling block. The etching process is self-minding, and the only turnoff here is if you use ferric chloride and get it on you or your clothes. It does not take Perry Mason to spot a careless user of ferric chloride. If you like speedy etching, you borrow the family aquarium pump and allow the airstone to bubble through the etchant while it is working. If you value your fish, use this airstone for etching only! The whole process is so simple that if PC etching was your excuse for not building, that excuse has now vanished.

Sure, you have put all the electronics together; you have even located a suitable keyboard. James Electronics supplied mine and it fulfilled the important requirement that each key have uncommitted contacts that were easy to solder to. When my keyboard arrived, it took the eagle eye of one of my harmonics to spot the fact that where there should have been a "Q", there was instead an "E". A letter to James brought speedy relief for this little problem, which is one of the many reasons that they are a favorite source for me.

Fig. 3. Letters/figures indicator. Common anode MAN 64 7 segment 0.6" LED readout. Source: S.D. Sales.

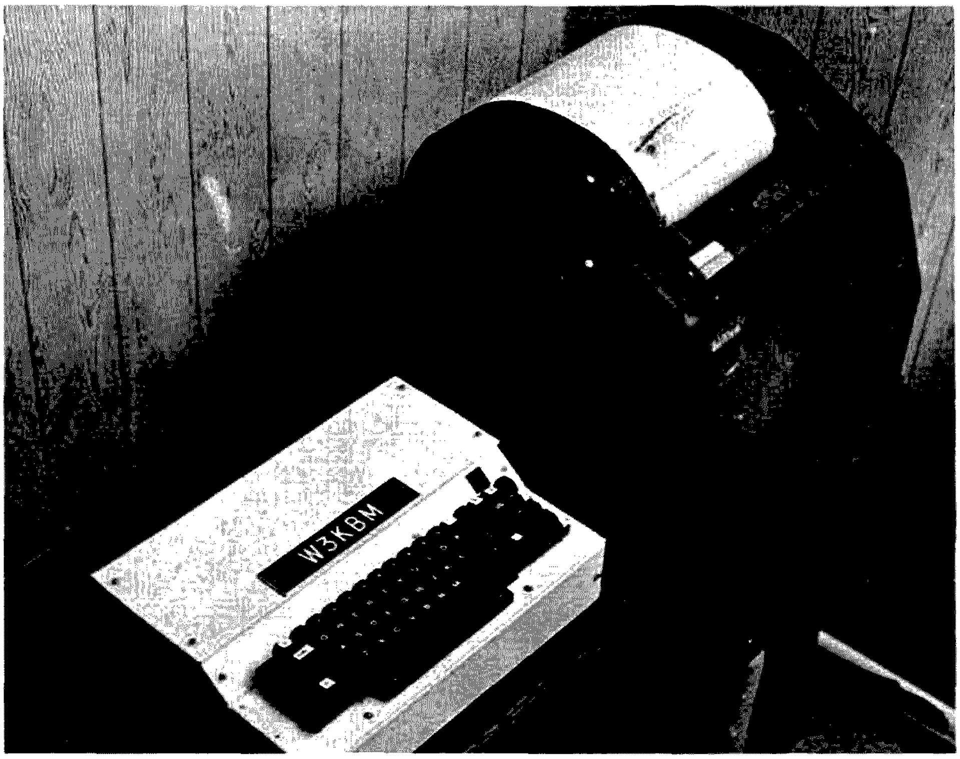


Naturally, you know that the TTL chips use five volts and that a power supply was constructed, but I am not going to bore you with that fundamental other than to say it used a 309K regulator as a matter of good practice.

Now we get down to an emotional problem that we have all encountered. It can be spelled out in one great big word . . . packaging.

This is where the companies that make commercial gear have it over all but the most talented of us. We can put the electronics together, make it work, fix it . . . all those good fundamental things . . . but the finished product sitting in its ho hum housing looks less than aesthetic.

As you can see from the photographs, the bare skeleton foundation is made up of particle board ends, a masonite bottom, and some imagination as to what fitting final shape might be desired. The exact dimensions used are shown in the sketch. Sheet vinyl, a white background speckled with gold splashes, was purchased at the local variety store. Masonite panels were cut to fit the various areas and each panel was carefully covered with the vinyl sheeting using ordinary white glue as the adhesive. The main foundation unit was given similar



The keyboard with the RTTY machine that it serves.

cosmetic treatment. The matrix was mounted in place, as was the keyboard, and the wiring from keyboard to matrix was installed. Care was taken in two areas of this wiring: first, that all wires between matrix and keyboard were long enough to completely remove the matrix without disturbing the keyboard, if and when work might have to be done on the matrix; and secondly, the wire used in this operation was the most flexible stranded wire I could get to avoid putting any strain on the small solder tabs on the keyboard.

The balance of the electronics was installed inside the case, and since the unit is so relatively large in relation to the size of the total electronics packages, space was no problem. The entire power supply was built up on the rear panel of the unit. As you can see from the photo of the finished product, not only was the execution of the electronics passably done, but the finished total package is not something to bring funny looks from the uninitiated.

There is one final bit of show biz that I added to the electronics package. In Lou's original version, there are two LEDs which show the keyboard mode, namely letters or figures. I added the circuit shown in Fig. 3.

Basically, it is a seven segment LED display that shows an "F" when in the figures mode and an "L" for the letters mode. This is both an operating convenience and a bit of pizzazz for the visitor to the shack, who often is more taken with the blinking lights than the actual fact that you can communicate.

To sum it all up: Search out your projects on the basis of need, throw in pocketbook practicality, analyze the unit to see how you can go modular for ease of construction and eventual troubleshooting, and don't forget that an aesthetic package is a valuable detail that is within your abilities. Put them all together and you will find yourself entering the ranks of the builders and enjoying the results. ■

Finished keyboard. Black rectangle in upper right hand corner of small slanted panel is the LED figures/letter indicator. Note that some of the keyboard characters graphics such as the #sign had to be added so they appear on their own key. Also note that, as with most of these keyboards, most of the keys, particularly the numbers row, had upper case symbols above the numbers. They were blacked out with the aid of a resist pen. This accounts for the clean uncluttered look of the keys.

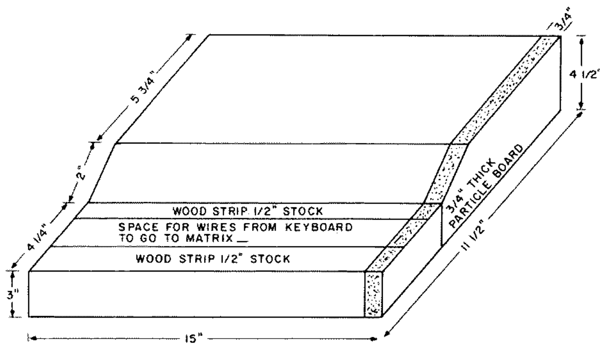


Fig. 4. RTTY keyboard case dimensions.

Wilson HT Mods

- - heavy duty p.s. required

Edward B. Beach K4MKX
5112 Williamsburg Blvd.
Arlington VA 22207

In 1972 I got bitten by the two meter FM bug and bought one of the first Genave GTX-2 transceivers in the Washington DC area. I was most impressed with its ten push-button channels and 1 Watt/25 Watt power capabilities for local repeater and simplex operation. Only later did I discover the rig was lacking in adjacent channel selectivity, which only became a problem when I was trying to work 94 simplex within ten miles of our local 91 repeater.

At any rate, I secured the new rig under the dash of my VW with a pair of hinges with padlock hasps and two stout padlocks to discourage would-be ripoff artists. I used this arrangement for four years very successfully and even survived one break-in attempt while the car was parked on the street near my office. At this time, I decided that a less visible and conspicuous mobile installation was needed. Besides, there had been numerous occasions when I could have used a portable rig to help out with local traffic from remote locations during boat races, hamfests, and so on.

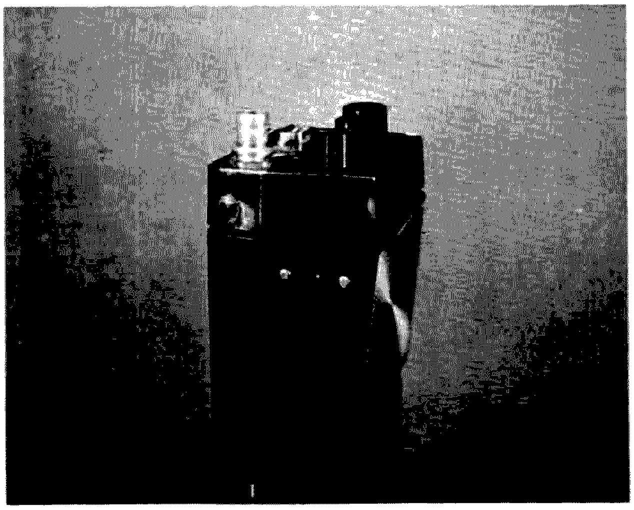

Fig. 1. BNC connector and external power jack.

The GTX-2 is now a base station, and I have a new portable/mobile setup which I consider to be just about the best of all possible arrangements. The rig is a Wilson 1402 handie-talkie that goes with me, mobile and portable.

In the VW I have a 5/8 whip mounted in front of the windshield (total coax length, two feet!) which goes to a 25 Watt amplifier in the trunk. The cable from the amplifier feeds into the glove box of the VW which is the home of the Wilson when I'm in the car. An external power cable and a home brew speaker-mike/touchtone pad complete the mobile installation.

The first (and most difficult) step in setting the Wilson up for mobile operation is to replace the TNC or F connector supplied with the rig with a BNC bulkhead connector. This is so you can quickly and easily remove the rubber ducky antenna and connect the mobile antenna.

I think it took me about a week, after I first looked at the inside of the Wilson, to get up enough nerve to tackle the job. Virtually everything must be disassembled to get to the antenna connector, and I am known to have all thumbs on both my hands when it comes to working on small things in tight places. At long last I undertook the job, and surprisingly enough everything went very well and without mishap. I unsoldered the leads from the original connector and removed it from the panel. The hex-shaped flange on the bottom of the original connector had been filed by the factory assemblers to fit the small space available, so I traced the outline of the flange on a 3/8-32 nut and ground it to the same shape. I threaded a second 3/8-32 nut tight up onto the new BNC panel connector. This nut would later be run down from the outside to tighten the connector to the panel of the Wilson. The D-shaped hole in the panel was reamed out with a 3/8" drill so the BNC connector could be screwed into the ground-off nut on the inside of the panel.

Everything went just as planned, and while I had the unit apart to install the antenna connector, I decided I might as well install a jack to power the rig from the car's electrical system. There appeared to be lots of room just above the push-to-talk button on the side for such a jack. I bought one of those Japanese connectors sold by Radio Shack and Lafayette for just such purposes. I also picked up a package that had a pair of mating plugs for the jack. I learned later that the two plugs were not the same kind, but found how to use

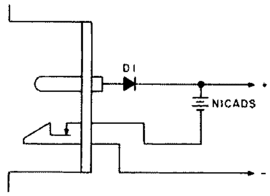

Fig. 2. Power connections.

both to good advantage, as I'll explain.

Fig. 1 shows the newly installed BNC connector and the external power connector jack. If you look closely, you can see the 3/8-32 nut that tightens the BNC connector to the panel. To drill the holes for the power connector, I used a hand-held drill bit to slowly drill the three holes. You don't get much torque or speed this way, but you can drill very clean holes in the plastic. If you try to use an electric drill, even a variable speed type, you'll probably end up scratching, gouging, or melting the plastic case.

Fig. 2 shows in a combined pictorial-schematic representation the connections of the external power jack. D1 is a junk box silicon rectifier and was installed for two reasons: first, to prevent damage to the rig by hooking up the external power source backwards; and second, to give a 0.7 volt drop to the nominal 13.6 volts supplied by the car's electrical system since the Wilson normally operates from 12.0 volts.

When I started to wire up the plug for this connector, I discovered that the two plugs I had bought were not the same type, although at first they appeared to be identical. They were both the same length and outside diameter, but the sizes of the holes in the center were quite different. The jack I had bought had a small diameter pin in the center which fit one of the plugs perfectly. This one I used to supply power from the car, since it would disconnect the nicads in the Wilson.

I made a happy discovery regarding the second plug, which had a much larger diameter hole in the center and fit the jack sloppily. Because of the loose fit of the plug on the center pin of the jack, when this plug was inserted into the jack the nicads were not disconnected, yet an electrical connection was made to both jack connections and thus to the nicads. Thus, by using this ill-fitting plug, I could parallel the nicads in the Wilson with an external power source for charging purposes. This is exactly what I did since I had not bought the Wilson charger. Now charging the nicads is ever so much simpler and handier than with my previous jury-rig of nails and clip leads.

The modified Wilson works beautifully as a mobile rig. It lives in the glove box, and the speaker-mike goes on the dash, right over the broadcast radio. At this point, the only problem I had was that I needed to fit a BNC connector on the Wilson rubber ducky antenna or I had to buy a new one with a BNC connector. The latter did not appeal to my Scotch nature, so I started looking for an F-to-BNC adapter. When I did finally locate one, I found that it cost almost as much as a new antenna and would also add about two inches to the already long antenna. Back to the drawing board.

It was about this time that a friend, WB3AXR, noticed that the internal threads at the rear of the BNC connector just happened to be 3/8-32. This meant that if the mutilated hex flange of the original Wilson F connector were ground completely off or otherwise removed, the connector would screw right down into the standard UG88/U BNC connector. Fantastic! Jim also happens to have a lathe and volunteered to perform the required surgery, although it could have been done with a file or a grinder almost as easily.

Fig. 3 shows the assembly, while Fig. 4 shows the adapter installed on the Wilson rubber ducky. The 3/8-32 nut is put on to lock the F connector to the BNC housing. All in all, a very nice compact adapter at very little cost. Thanks, Jim.

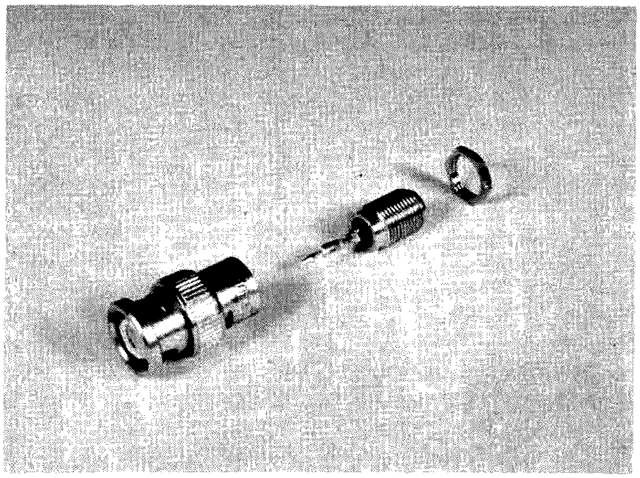

Fig. 3. Construction of the F-to-BNC adapter.

Incidentally, WB3AXR also has a Wilson 1402 and he too hesitated before tackling the job of changing the bulkhead antenna connector, despite his proven mechanical abilities and skills. However, when he saw that I, with my all-thumbs hands, had done it without mishap, he too made the conversion successfully.

The next thing I did to the rig cost me some money. The leather case of the Wilson is very well made, and does a great job of protecting the rig from scrapes and bumps, but it is very inconvenient when it comes to putting the rig on a trousers belt. One has to practically disrobe to thread the belt through the built-in belt loop on the back of the case. I took the case to a local leather goods shop and for two dollars had two male snaps installed as shown in Fig. 5. They do not interfere with the normal closing of the flap, and certainly make it handy for snapping the rig on a belt.

As indicated earlier, there is one more feature that was added to make a truly complete mobile/portable rig. This is a home brew speaker-mike/touchtone pad. I had bought the Wilson speaker-mike, and found it very useful in mobile operation.

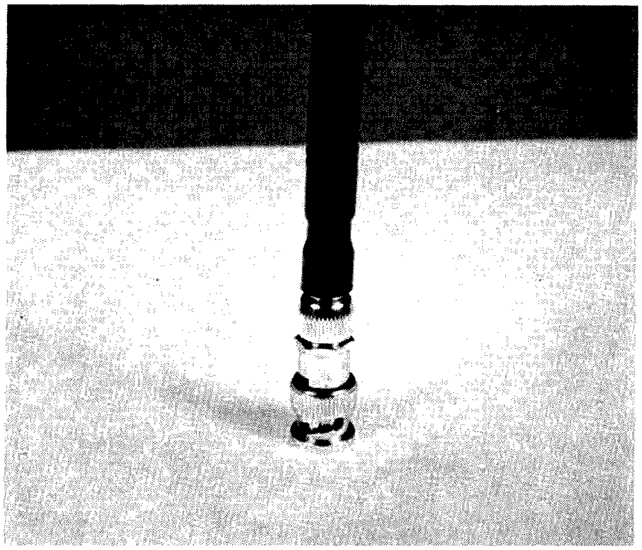

Fig. 4. Finished F-to-BNC adapter.

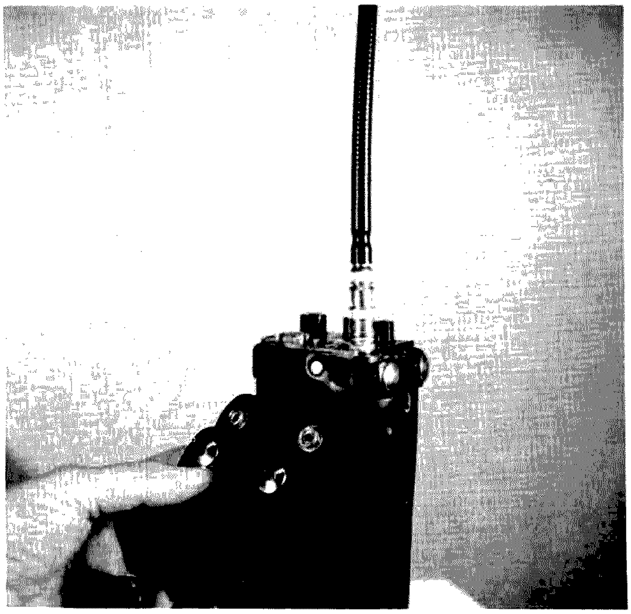

Fig. 5. Added snaps on the leather case.

Adding a touchtone pad to the rig, however, posed several problems. If I built the pad into the front of the transceiver case, it would not be convenient to use in the car. A couple of friends had modified the Wilson speaker-mike to include the touchtone pad on its rear. This method, unfortunately, involves a great deal of surgery on the speaker-mike case as well as a lot of delicate wiring and lots of epoxy to hold the thing together. The end result is very nice, but I'm quite sure I would blow it. Besides, I didn't like the idea of losing the molded mike hanger button on the back of the speaker-mike.

For these and other reasons, I decided to roll my own. I looked around for a suitable enclosure to house the parts, but found that most metal boxes (miniboxes and the like) were just not the right size and shape for the job. Then my roving eye landed on a small transistor radio that I had thrown in the junk box to "fix someday." I think I had paid $2.50 for it at a special sale and it would provide a loudspeaker and battery as well as a hand-size enclosure for the home brew speaker-mike. Not bad!

I had bought the 16 button touchtone keyboard kit of parts from Data Signal* some time ago and, because of my proposed custom design, I had not put the thing together yet. Indeed, I had ultimately decided that I would use the parts but not the circuit board in my custom installation, so it was quite fortuitous that I hadn't put it together. A quick eyeball measurement showed that everything should fit very nicely in the radio case, so I decided to go ahead with my plan.

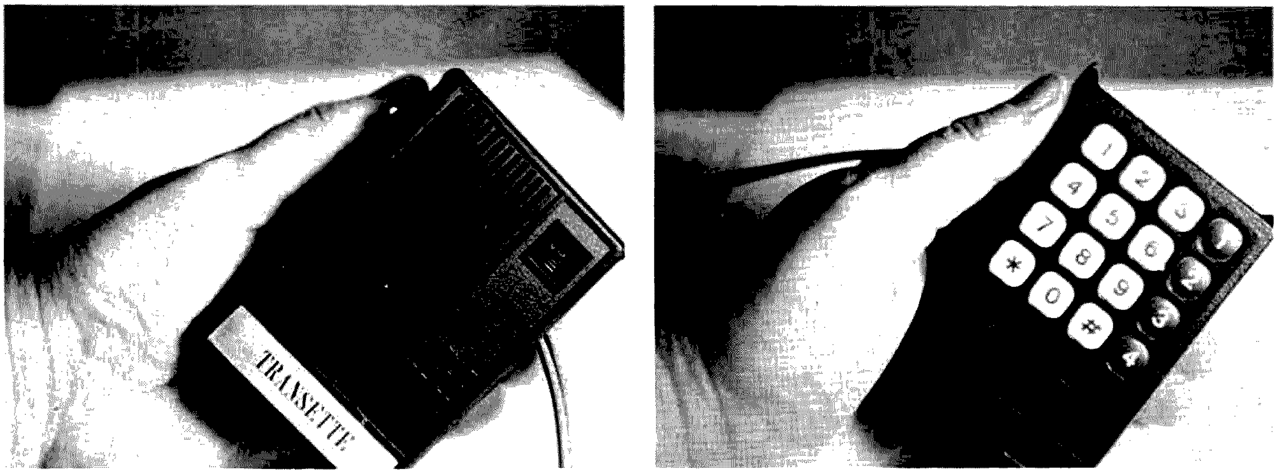
The first step was to remove the radio circuit board and trace its outline on a piece of paper. The paper pattern was then used to cut out a piece of perfboard (holes on 0.1" centers) to replace the radio circuit board. I used perfboard because it makes no sense to make a printed circuit board for a custom one-of-a-kind project. More time would have been spent laying out the circuit on paper than was needed to complete the point-to-point wiring! I did use IC sockets, however, since soldering multiple leads to IC pins can be harmful to their health – a dead IC in such a situation can quickly cool off enthusiasm for the project.

Fig. 6 shows the final results from the outside. The switch on the right side is an on-off switch that is not at present in use. It was used in the original version only. The small white button near my thumb in Fig. 6(a) is the push-to-talk switch, a microswitch epoxied to the perfboard and extending through the original volume control opening in the case. The microphone, which I bought from Wilson, is located behind a series of small holes drilled in the vertical louvres, about a half inch from the push-to-talk button. The mike is sandwiched between the perfboard and the front of the case, held in place and cushioned by a thin sheet of foam rubber. The cord to the rig exits the unit through the original tuning capacitor opening in the right side of the case. Although the cord looks like a piece of lamp cord, it is actually stereo cable with a vinyl jacket and has two separate shielded cables. The cable is firmly anchored to the perfboard just inside the opening to prevent yanking out the wiring accidentally.

Fig. 6(b) shows the 16 button pad mounted on the back cover of the case. To get a template for drilling the mounting holes for the pad, I used the paper trick again. This time I actually pressed a piece of paper up against the back of the pad to transfer an impression of the four mounting pins and the nine terminal pins to the paper.

---

*Data Signal, Inc., 2212 Palmyra Road, Albany GA 31701.



A *Fig. 6. Front (a) and rear (b) views of the speaker-mike/pad.* B

The paper is then rubber cemented to the case while drilling the holes.

Not visible in Fig. 6 is a small hole drilled in the top end of the case for access to the output level control. The output is adjustable from zero to about 900 mV, which should easily drive any medium to high impedance mike circuit.

Fig. 7 is the diagram of the circuitry inside the case. As indicated earlier, the on-off switch was eliminated after the photos were taken. Standby drain is only 20 uA, changing to 4 mA when the circuit is activated by pressing any of the pad keys. The 100k Ohm resistor across the PNP switch transistor, Q2, supplies the standby current to the circuit. When any key is pressed, the 20 uA current is transferred to the common terminal of the pad and to the base of Q1, turning Q2 on to power the circuit.

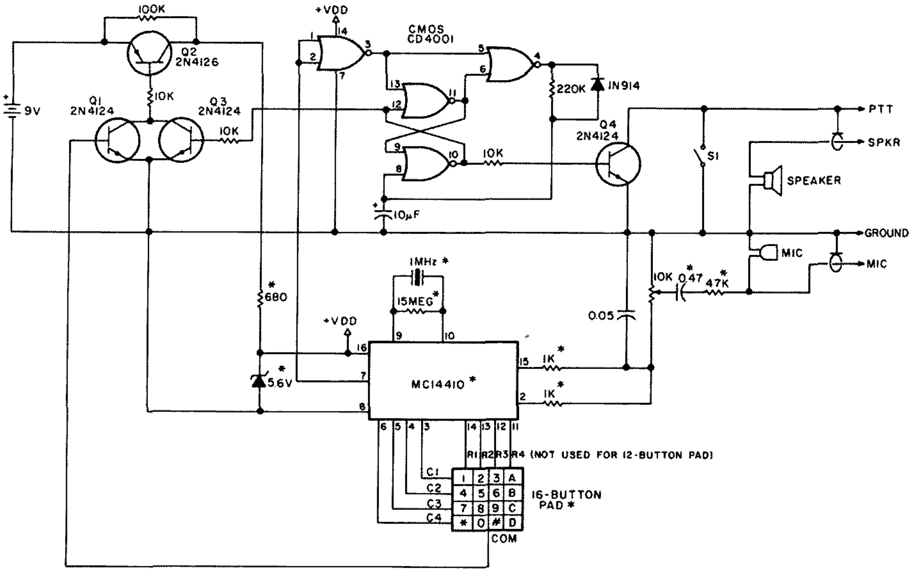


Fig. 7. Schematic of the speaker-mike/pad.

The four gates of the CD4001 IC form a retriggerable monostable to key the transmitter via Q4. The monostable also drives Q3 to keep power on to the circuit at the same time. The 220k Ohm resistor and 10 uF capacitor determine the shutoff delay of the monostable. As shown, they provide about a half second delay when a pad key is released. For a longer delay (if you're a slow dialer!), increase either value – the resistor is easiest.

S1 is the push-to-talk switch and parallels Q4. Notice that the "shield" of the speaker lead is the push-to-talk line and is grounded only by Q4 or S1. The shield of the microphone lead is the only "ground" in the circuit.

And there you have it – the "compleat portable/mobile Wilson." Now if I could only fit a CMOS synthesizer in there some way . . . ■

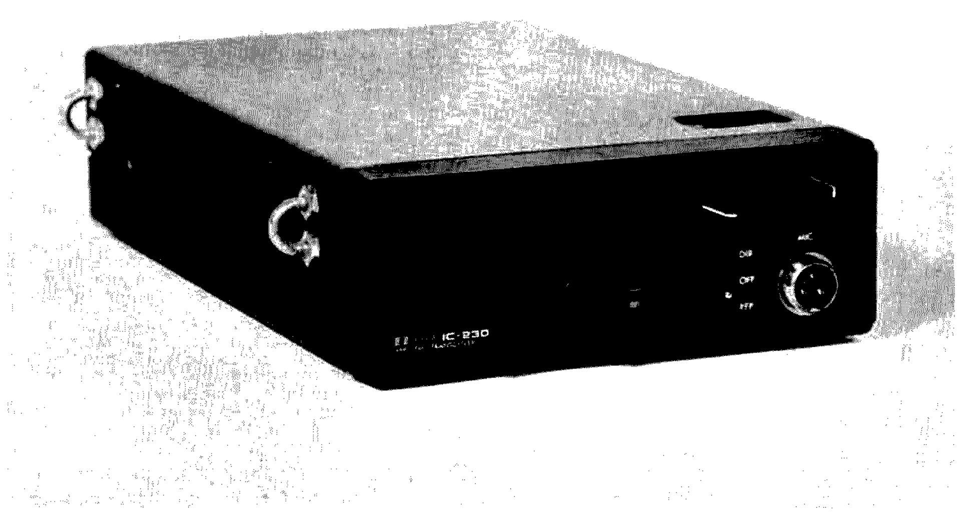
Try These IC-230 Mods

- - improving a popular transceiver

The Icom IC-230 appears to be one of the more popular synthesized two meter rigs on the market today. In its stock form, it tunes from 146.01 MHz to 147.99 MHz in 30 kHz steps, selectable by a 146-147 MHz push-button switch, and rotary switches for the 100 kHz and 10 kHz segments. The power switch is used to select either "direct" or "repeater" operation, and an additional slide switch on top of the rig sets the transmitter to the standard repeater offsets of 600 kHz above or below the selected receive frequency.

Numerous modifications may be applied to the IC-230 to further improve its versatility. This article explains the engineering and construction of 1) an inexpensive method of adding all "split" repeater and simplex frequencies, with easy selection and display; 2) a method for providing automatic repeater offset and simplex operation, so the user need only dial the receiver frequency on the front panel; 3) the utilization of a spare crystal socket, with trimmer, already in the rig, to provide for an additional non-standard repeater offset frequency; and 4) a high/low power switch, with variable low power from about 1/2 Watt upward. In addition, when the switch is in the low position, all front panel lights except the meter light are extinguished, to preserve battery life during portable operation.

All of these modifications are independent of each other, so any or all may be incorporated as desired.



Front view of the IC-230, showing location of the "normal-split" frequency switch. Moving the toggle to the right increases the frequency shown on the front panel by 15 kHz.

15 kHz Step Capability

This modification incorporates an added front panel switch which raises the frequency dialed by 15 kHz. This method covers all split channels between 146 and 148 MHz, and is cheaper and easier to use than adding extra crystals into the "A", "B", and "C" positions of the 100 and 10 kHz crystal bank.

Before going into the procedure for adding the split frequencies to the rig, a brief explanation of the synthesizer is in order (Fig. 1). The heart of the synthesizer is a voltage controlled oscillator (VCO). A crystal-controlled local oscillator (LO) generates a frequency which is determined by the position of the 100 kHz rotary switch. The LO frequency is multiplied by nine and subtracted from the VCO frequency. The resultant is phase compared to the control oscillator (CO) frequency, which is also crystal-generated and determined by the position of the 10 kHz switch. The phase comparator applies an error voltage to the VCO, which remains locked to the desired receive frequency minus the first i-f of 10.7 MHz. The proper transmit frequency is generated by a third crystal oscillator and mixer, which adds to the VCO output 10.7 MHz for simplex operation, 10.1 MHz for a -600 kHz transmit offset, or 11.3 MHz for a +600 kHz transmit offset.

This system has an interesting advantage: All transmit and receive frequencies are independent of possible spurious outputs in the LO and CO, since these are merely control circuits for the VCO.

Circuit Description

Note: Throughout this article, all components added to the IC-230 are given three-digit identifier numbers. Other components originally in the rig are identified in the

same manner as they appear in the IC-230 schematic.

Figs. 2 and 3 show the circuit used to obtain 15 kHz step capability. Each crystal in the LO may be set exactly on frequency by a trimmer capacitor located near the crystal. However, when capacitor C111 is switched in series with one of the crystals, its frequency is raised by about 1.7 kHz, or 15 kHz at its ninth multiple. Capacitor C110 is necessary to swamp out additional capacitance to ground obtained from the added wiring. Otherwise, the range of each crystal trimmer is exceeded before bringing the crystal back on frequency, after these components are added.

Since C111 affects each LO crystal differently, it is probable that a frequency increase of exactly 15 kHz on the ninth crystal multiple will not be obtained with each crystal. For a given value of C111, each LO crystal will exhibit a different frequency "spread" when C111 is switched into and out of the circuit. Ideally, the spread on the ninth multiple should be as close as possible to 15 kHz. To properly align the seven crystals in the LO, it will be necessary to place a capacitor (C100-C106) in series with some of the LO crystals. These capacitors effectively narrow the spread of the LO crystal to which one is attached.

Construction and Alignment

Remember that the 13 MHz LO crystals are switched directly into the oscillator circuit by the 100 kHz rotary switch, so good rf construction practices, such as keeping lead length to a minimum, should be used when working in this area.

Before beginning this modification, connect the IC-230 to a dummy load and attach a VHF frequency counter to display the transmitted frequency. Icom requires that each channel of the rig be within 750 Hz of the correct frequency. Check the CO alignment by reading each frequency from 146.01 to 146.28 in 30 kHz steps, which checks each of the ten CO crystals against one LO crystal. Next, check the LO by reading 146.01 to 147.81 in 300 kHz steps, which checks each LO crystal against one CO crystal. If there are any discrepancies, be sure you know which circuit is out of adjustment before changing the crystal trimmer settings. The IC-230 manual will be of help here.

Now begin construction of the circuit as shown, using the schematic (Figs. 2 and 3) and photographs as a guide. Install all components *except* C100-C106. Instead, leave the wires to P-1 intact. Switch S-100 is installed by removing the front panel of the rig and placing the mounting hole in the chassis above and between the two rotary switches. S-100 is mounted horizontally, and the toggle extends through the front panel between the 100 kHz and 10 kHz display windows. Before drilling through the front panel plastic, place a piece of masking tape on the other side, so a clean hole results. Use a small circular file to elongate the hole to accommodate S-100.

After installing these components, set C111 to midrange and close S-100. In my rig, S-100 is mounted so that when the toggle is facing left, the switch is closed, setting the rig up for standard 30 kHz step frequencies. Now recheck the LO for correct alignment as before, and adjust each LO crystal trimmer as necessary. Each trimmer should be close to its full open position. Record the frequencies obtained with each LO crystal, down to the nearest 100 Hz, in a column.

Now open S-100 and record the new frequencies obtained with each LO crystal in another column. Determine the spread of each LO crystal by subtracting the two frequencies obtained with that crystal. Choose the LO crystal which gives the smallest spread, and adjust C111 to set this spread to 15 kHz. Now the other LO crystals will all yield spreads above 15 kHz. Capacitors C100-C106 will be used as necessary to decrease the spread of the other LO crystals. These capacitors should be silver mica or polystyrene, to insure good temperature stability. A 100 pF capacitor used in this manner will decrease the spread of the associated LO crystal by approximately one kilohertz. The addition of these capacitors also necessitates readjusting the LO crystal trimmers, with S-100 in the normal position, for the correct standard frequency. In my IC-230, five of the seven crystals in the LO needed a 100 pF series capacitor, and the other two required no capacitance here. This combination resulted in all frequencies being within 400 Hz of the desired channel frequency.

Since I spent considerable time and effort obtaining this close tolerance, I recommend being content with the more relaxed 750 Hz standard used by Icom, since no noticeable "off frequency" distortion occurs in this case. This 750 Hz standard allows for a frequency spread of between 13.5 and 16.5 kHz on the ninth multiple of each LO crystal.

It is possible that some of the LO crystals will be difficult to tune in the manner described. In my unit, one crystal stopped oscillating, evidenced by the S-meter light extinguishing, just before its ninth multiple was raised 15 kHz. Another LO crystal required a significantly smaller series capacitance than the others to obtain the desired frequency spread. Replacements from Jan Crystals were installed, and both problems were solved. Remember to follow crystal ordering procedures outlined in the IC-230 manual.

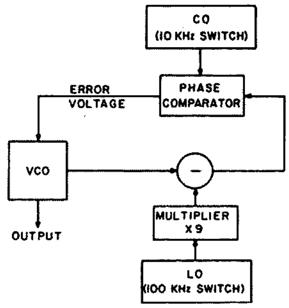


Fig. 1. Block diagram of the frequency synthesizer portion of the IC-230.

Automatic Simplex and Repeater Offset

The circuit described here automatically selects a +600 kHz transmit offset for receive frequencies of 146.01 to 146.37 and 147.00 to 147.39, simplex operation for 146.40 to 146.58 and 147.42 to 147.57, and a -600 kHz transmit offset for 146.61 to 146.97 and 147.60 to 147.99, all obtained with the power switch in the REP position and the repeater select switch in the REP A position. In addition, position A on the 100 kHz rotary switch sets the transmit offset at -600 kHz, and position B sets the offset at +600 kHz, for both the 146 and 147 MHz band

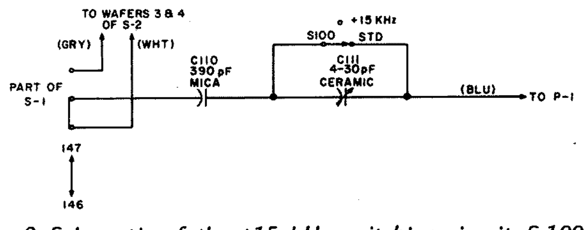

Fig. 2. Schematic of the +15 kHz switching circuit. S-100 is the miniature toggle switch that is mounted on the front panel of the rig. Opening S-100 places C111 in series with the particular LO crystal being used, raising the ninth multiple frequency by 15 kHz.

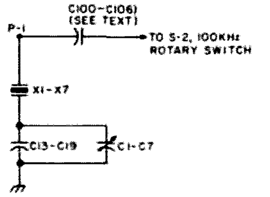
Fig. 3. Capacitors C100-C106 are mica types placed in series with each LO crystal, as necessary, to equalize the effect of C111. A 100 pF capacitor here decreases the frequency spread of its corresponding LO crystal by about 1 kHz at its ninth multiple, when S-100 is switched between the STD and +15 kHz positions.



segments. This provides for convenient selection of normal and reverse repeater operation, and simplex on the standard frequencies, for both the 146 and 147 MHz bands. Also, if the split repeater and simplex frequencies are added as described before, the system automatically selects proper transmitter offset for either the California or new York plans for split repeater setup. If the power switch is placed in the DIR position, the automatic transmit offset feature is defeated, and all frequencies are set up for simplex operation.

Circuit Description

The correct transmit offset is determined merely by the position of the 100 kHz rotary switch. The offset is +600 kHz for positions B, 0, 1, 2, and 3; simplex for positions 4 and 5; and -600 kHz for positions 6, 7, 8, 9, and A. The circuit consists of two parts, shown in Figs. 4 and 5. The first part wires the front wafer of S-2, which is the 100 kHz rotary switch, along with the power switch S-4, into the logic required for automatic transmit offset. The second part combines some of the 30 kHz spacing of the crystal switching logic, originally utilizing the first two wafers on the 100 kHz rotary switch, into the second wafer alone.

The original purpose of wafers 1 and 2 of the 100 kHz switch S-2 is to switch a regulated 9 volt supply to one of three lines, labeled A, B, and C, which are routed to the 10 kHz switch CO-S-1. This allows the 9 volt supply access to the CO module only when the combination of LO and CO crystals selected corresponds to the frequency shown on the front panel.

The front wafer of S-2 switches the 9 volt supply to lines A, B, and C in a manner consistent with operation on the 147 MHz segment of the band, while the second wafer is set up in a similar manner for the 146 MHz segment. In effect, when operation is changed from 146 to 147 MHz, line A is transposed to line C, line B to line A, and line C to line B. This is also easily accomplished by adding switching transistors Q100-Q105. Each line (A, B, and C) is connected to two transistors, corresponding to 146 and 147 MHz, which is still determined by pushbutton switch S-1. Activating the proper transistor allows the regulated 9 volt supply to pass to the correct line from the second wafer of S-2, which is the only wafer now needed for this switching logic.

The IC-230 uses diode crystal switching for determining the desired transmit offset. This method is simple in that the 12 volt supply is the only thing that need be switched. With the REP A-B switch in the REP A position, +12 volts is switched to the power switch which, if in the REP position, transfers the 12 volts to the rotor of the front wafer on the 100 kHz rotary switch, which diverts the 12 volts to the correct offset crystal switching circuit. With the power switch in the DIR position, the 12 volts is sent directly to the crystal switching circuit that provides simplex operation. If the REP A-B switch is moved to REP B, the 12 volts is diverted to the auxiliary transmit offset crystal located on the LO crystal socket SO-1, if this modification is also incorporated in the rig. The two diodes attached to the 100 kHz rotary switch allow the REPTR indicator light to come on only when a repeater frequency is dialed.

Construction

Although the IC-230 is densely wired in the vicinity of the 100 kHz rotary switch, there should be no problems accomplishing the changes if care is exercised.

Remove the top and bottom covers, front knobs, and front panel from the rig. The mic plug need not be removed from the front panel, if the panel is rotated away from the rotary switches. Remove the 146-147 MHz push-button switch from the top of the rig by unsoldering as many wires (make note of their positions!) as necessary to enable the switch to be moved away from the front two wafers of the 100 kHz switch. Turn the rig over and remove the screws from the two 3-lug terminal strips near the 100 kHz switch. Set the dial of this switch to the zero position, and remove the dial. Slide all obstructing panel lights rearward until they are free of their respective grommets, and move them out of the way. Now remove the control nut holding the 100 kHz switch in place, and slide the switch back about a centimeter to gain access to the front wafer.

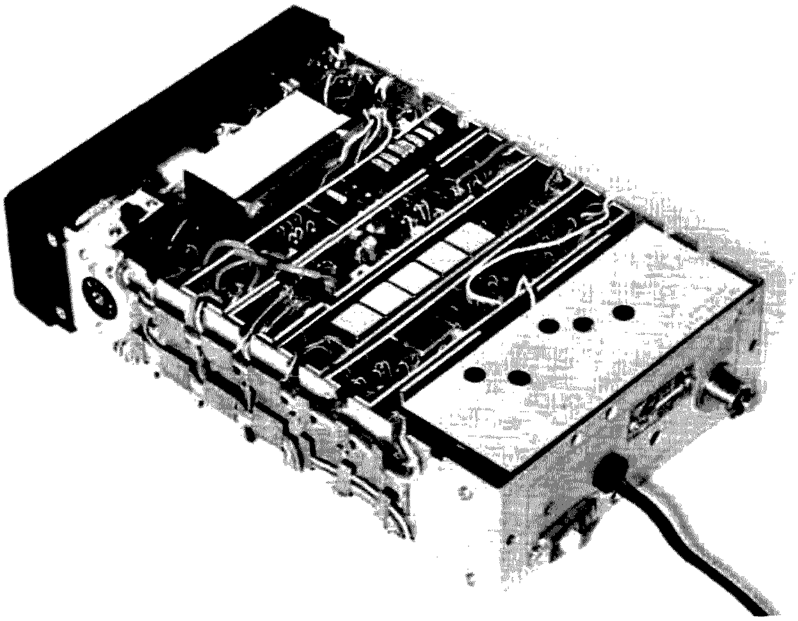
Attached to the front two wafers of the 100 kHz switch are a white and a gray wire from the 146-147 MHz switch, and a line A (orange), line B (blue), and line C (red) wire, which connect the 100 kHz switch to the 10 kHz switch. All of these wires should be removed at both ends, and their positions noted.

Now remove all additional wiring from the front wafer of the 100 kHz switch, and leave all wiring on the second wafer intact. Interconnecting wires between wafers may be cut where they first attach to the second wafer before the portion attached to the first wafer is removed.

On the bottom side of this switch, note that the front and second wafers each had two lugs connected together to a pink wire. These represent switch positions A and B. The other four lugs on this side represent positions 9, 8, 7, and 6. All lugs appear in the same order as the numbers in the selector window when the frequency knob is rotated. Keeping this in mind, connect the 6, 7, 8, 9, and A lugs together, the 0, 1, 2, 3, and B lugs together, and the 4 and 5 lugs together. The pink wire attaches to the A and B lugs of the second wafer only.

Now remove the wires which go to the REP A-B switch, located on top of the rig, and remove the other end of the wire from this switch to the power switch. Attach an extension of the purple wire, which switches the 11.7 MHz crystal, to lugs 0, 1, 2, 3, and B of the 100 kHz switch. Attach an extension of the light green wire, which switches the 10.1 MHz crystal, to lugs 6, 7, 8, 9, and A of the same switch. The 10.7 MHz crystal is already connected by a pink wire to the DIR side of the power switch. Connect a wire from here to lugs 4 and 5 of the 100 kHz switch. Connect the two diodes between the 100 kHz rotary switch and the REP A-B switch, as shown. Connect a wire from the 100 kHz switch rotor lug to the REP side of the power switch, S-4.

Attach a wire to the +12 volt supply, located on pin 3 of the accessory socket, and attach the other end to the center terminal of the REP A-B switch. Connect the REP A side of this switch to the same center terminal of the power switch from which a wire was previously removed. If this modification is used alone, the switch on top of the rig may be left permanently in the REP A position. However, if the non-standard



Top view of the IC-230. C111 is located directly in front of the seven LO crystals, and is mounted on a small right angle aluminum bracket. C100-C106 are attached to P-1, which is located next to C111. The PC board used in the automatic repeater offset modification is shown in place on the lid of the CO module. The additional non-standard repeater crystal is located on the far side of the LO crystal socket, and the three-lug terminal strip is mounted on the side of the rig behind the REP A-B switch.

repeater offset modification is made, as described later, the REP B side of this switch will be used.

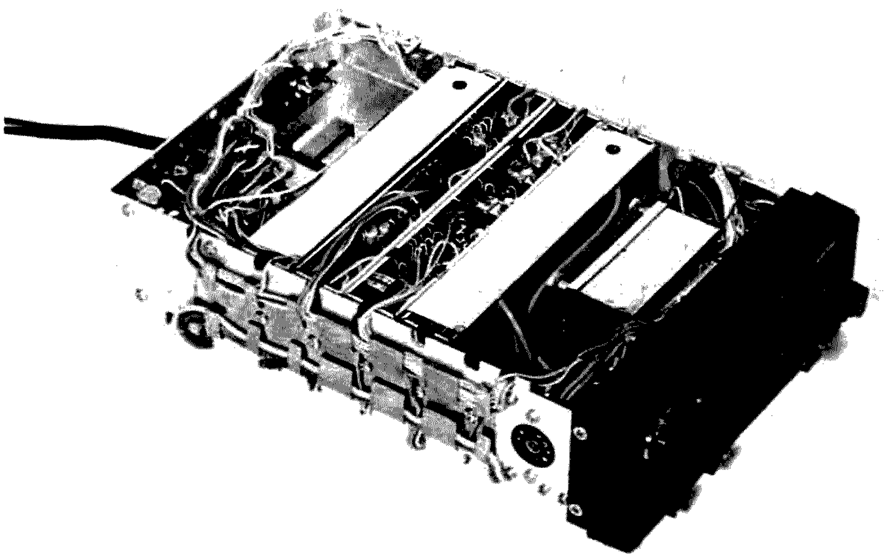
Now remove the lid to the CO shield box, located on the rear wafer of the 10 kHz switch, and cut a piece of PC board the same size as this lid. Etch and drill this PC board to match the schematic (Fig. 5) and photo, and mount it on the lid of the CO shield box after all components and wires are soldered into place. (Since this circuit is elementary, no PC board layout is given here, other than in the photograph. It is recommended, though, that all external wire connections be grouped to one side of the PC board, as shown in the photo, to facilitate installation.) It may be necessary to file the mounting spacers as short as possible so the components will fit next to P-1 on the LO module.

It should be noted that if both the automatic repeater selection and the split frequency features are added, there are two frequency combinations which will result in operation outside the two meter band. Normally, the simplex split frequency of 147.405 MHz is obtained by dialing 147.39 MHz and raising this by 15 kHz with the added front panel switch. However, if the power switch is left in the REP position, the transmit frequency will be 600 kHz higher, or 148.005 MHz. Therefore, for this simplex frequency, the power switch must be in the DIR position for correct operation. Secondly, if 147.99 MHz is selected, with the power switch in the DIR position and the frequency raised by 15 kHz, the receive and transmit frequency will be 148.005 MHz.

Non-standard Repeater Offset

This modification allows placement of an additional transmit offset crystal in the far right socket, which is presently unused, of the LO module. When the switch on top of the rig is placed in the REP B position, this new offset crystal is used by the mix module to determine the transmit frequency. This function operates regardless of whether the power switch is in the DIR or REP position, and when the non-standard offset is being used, the REPTR lamp lights dimly as an indicator.

If this additional repeater offset feature is added to the IC-230 without incorporating the automatic repeater offset modification, a separate switch will have to be used for this circuit, since the REP B portion of S-5 will not be available for this use.



Bottom view of the rig. The high/low power switch is mounted on the back panel of the rig, along with R120 attached directly to the switch terminals. The mix module contains the three standard transmit offset crystals, two of which are visible in their sockets.

Circuit Description

Fig. 4 shows that this new circuit is merely an addition

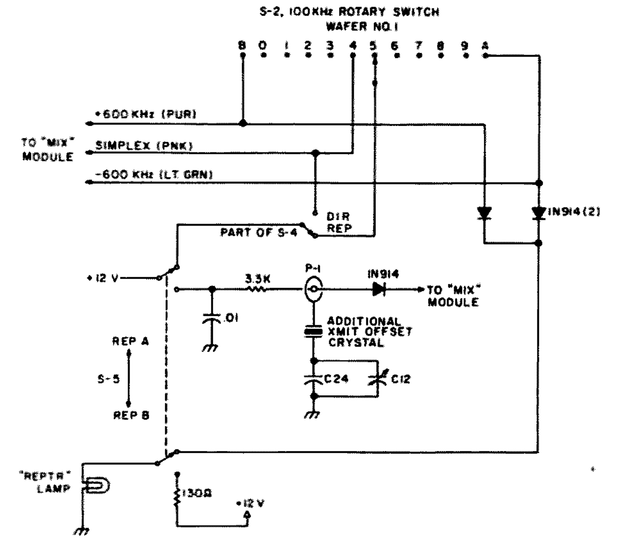


Fig. 4. Automatic transmit offset circuit, with additional non-standard repeater offset crystal. With S-5 in the REP A position, standard repeater, reverse repeater, and simplex transmit offset frequencies are determined automatically. With S-4 in the DIR position, simplex operation is possible on all frequencies. Moving S-5 to the REP B position places the non-standard repeater crystal into operation, and the REPTR lamp lights dimly as an indicator.

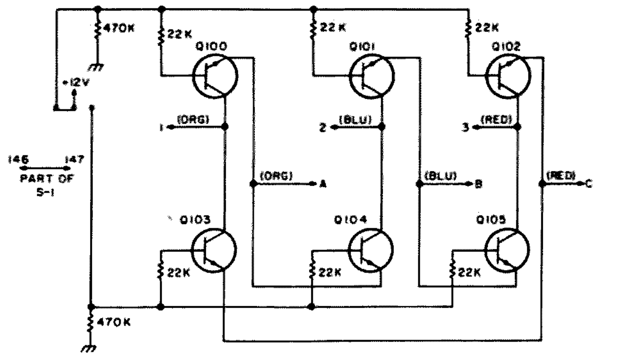

Fig. 5. Schematic of the PC board circuit which combines wafers 1 and 2 of the 100 kHz rotary switch into wafer 2 alone, allowing wafer 1 to be used as shown in Fig. 4. Q100-Q105 are silicon switching transistors. Lines 1, 2, and 3 are from wafer 2 of the 100 kHz rotary switch. Lines A, B, and C connect to their corresponding places on the 10 kHz rotary switch. All resistors are 1/4 Watt.

of one more crystal to the diode switching network already used to determine transmit offset, located in the mix module. When the REP A-B switch is in the REP B position, this non-standard offset crystal is switched into the circuit at the mix module, along with a 130 Ohm resistor in series with the REPTR lamp.

Construction

Begin construction by marking the position of and removing each wire on the mix board. This is the second module from the front on the bottom side of the rig, which contains the three transmit offset crystals. Now loosen the screws located on each side of the mainframe to which the module is mounted, and remove it from the mainframe. Drill small holes for the pin connector (if desired) and switching diode somewhere near the crystal end of the module. Install the diode and connector, and replace the mix module in the mainframe. Install a three-lug terminal strip at a convenient location in the rig, and wire it according to the schematic. The wire which runs between this terminal strip and the mix module should be routed under the bus clips on the side of the rig. Complete the modification by removing the REPTR lamp red wire from the power switch and moving it to the switch on top of the rig; finish wiring this switch by following the schematic.

The correct crystal frequency in this circuit may be obtained by adding the desired transmit offset frequency to 10.7 MHz, and installing a crystal of this frequency in the socket on the far right side of the crystal bank in the LO module. The transmit frequency may be set exactly by adjusting the correct trimmer while observing the transmitter frequency on a counter.

High/Low Transmitter Power Switch

In my unit, the high/low transmitter power switch is mounted on the back of the rig, and the circuit is similar to that used in the IC-22. In the HI position, the rig operates normally. When switched to LO, the transmitter power is reduced to about 1/2 Watt or more, determined by the setting of an added internal potentiometer. In addition, the low power setting turns off all front panel lights except the meter light, and the red transmit light, which operates normally. In this manner, the current drain on receive is cut nearly in half, which, along with the reduced transmit power, extends battery life when the rig is used as a portable.

Circuit Description

The EPS module, located next to the speaker, contains a control circuit which adjusts the voltage to the transmitter driver and final transistors, determined by the swr on the antenna, for protection purposes. In the low power position, a small PC-type pot is placed on the collector of Q1, as shown in Fig. 6, which lowers the voltage to the transmitter in the same manner. Also, the ground return on the 146, 147, REPTR, and the 100 kHz and 10 kHz dial lights is opened, extinguishing those lights.

Construction

Remove the EPS board, located opposite the antenna connector on the bottom side of the rig, and note that a 10k resistor is mounted on the foil side of the board, near the center. One side of this resistor is joined to a 4.7k resistor on the top side of the board. This is the point to which the wire to the high/low power switch should be attached. Find the white (ground) wires on the 146, 147, REPTR, 100 kHz and 10 kHz digit lamps, and connect them all to a single wire, which should be routed via the bus clips on the side of the rig back to the high/low power switch. Exposed connections should be covered

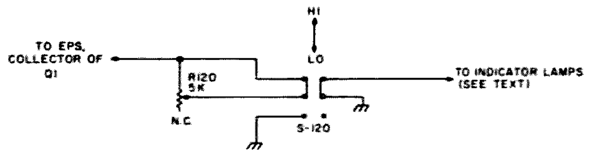

Fig. 6. The high/low power switch mounts on the back of the rig, and incorporates a circuit similar to that used in the IC-22. R120 is a PC mount pot, and may be soldered directly to the switch terminals. S-120 is a standard size DPDT slide switch.

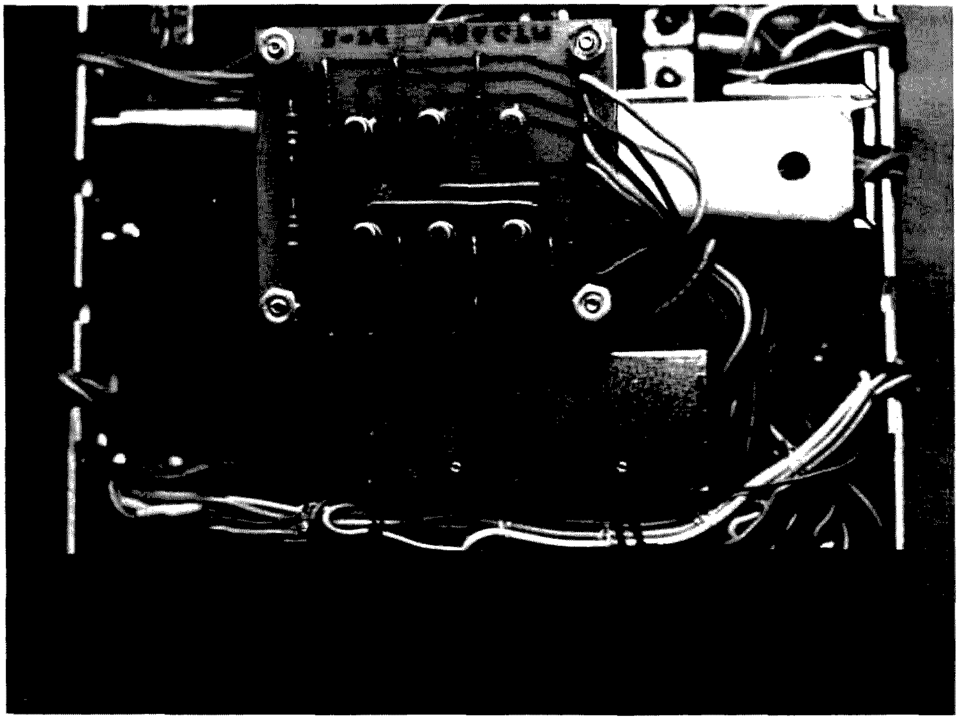

The PC board used for part of the automatic transmit offset modification is shown with all wires attached. From the top down, the wires are: 146 MHz; C; B; A; 1; 2; 3; gnd; 147 MHz.

with heat shrinkable tubing where appropriate.

When setting the low power with R120, key the transmitter and note that the meter still indicates relative rf power. This power can be reduced so that the meter shows a reading between 1 and 2 to obtain the greatest difference between the high and low transmitter power output. Any attempt at a lower power setting may cause the driver and final transistors to stop oscillating.

Conclusion

It is my experience that each modification described here plays a significant part in improving the versatility and convenience in operating the IC-230. In addition, some of these circuit principles could be applied to other rigs as well. For example, each crystal in a discrete channel rig could be raised by 15 kHz, to obtain a limited split channel capability. Some form of the automatic repeater offset circuit could be applied to other synthesized rigs. Finally, a switch which cuts off all indicator lights will prolong battery life on any rig when used as a portable. ■

Social Events

SALT LAKE CITY UT
APRIL 30

The Utah Computer Association announces the Utah Computer Fair to be held Saturday, April 30, 1977 from 1 to 5 pm at Fashion Place Mall. Purpose: To inform the community of the place and value of personal (hobby) computers in our world. Many of our members will be bringing their computers, both home-built and professional systems, demonstrating many different applications. We will also have some manufacturer representatives and local distributors present. This is an informational gathering; there will be no selling! For further *information, contact* Ernie Dixon, Fair Chairman, at home (6-9 pm) at 467-9100; or at work (8:30 4 pm) at 486-7481.

BROWNFIELD TX
MAY 1

The Brownfield Amateur Radio Club will hold a Swapfest on Sunday, May 1, 1977, in Brownfield, Texas.

WEST TRENTON NJ
MAY 1

The annual Delaware Valley Radio Association (W2ZO/WR2ADE) flea market and auction will be held on Sunday, May 1, 1977, 9 am rain or shine at the Villa Victoria Academy in West Trenton, New Jersey (the school is located adjacent to Rt. 29 near the junction of Rt. 29 and I-95). Talk-in on 07/67 and 146.52. Refreshments are available. Advance registration $1.00; $1.50 at gate. For additional information or tickets write: DVRA, PO Box 7024, West Trenton NJ 08628, SASE please.

FRESNO CA
MAY 6-8

The Annual Fresno Amateur Radio Club Hamfest will be held this year at the Airport Holiday Inn on May 6 and 8, 1977. For more information write Fresno Amateur Radio Club, Inc., 4788 N. Safford, Fresno CA 93704.

HERNDON VA
MAY 7

The Potomac Area VHF Society will hold its sixth annual hamfest on Saturday, May 7, 1977, from 8 am to 5 pm at Frying Pan Park on West Ox Road in Herndon, Virginia, which is approximately 15 miles west of Washington DC. Registration of $3 includes flea market or tail gate sales. Professional food and beverage catering and unlimited parking will be available. Talk-in on 146.52 and 31.-91. repeater. This is the hamfest formerly held in Westminster MD, but moved to Virginia because of the recently enacted Maryland traders law. For further information contact K3DUA or WA3NZL.

CORRECTION

On page 158 of the March issue of *73*, we published an erroneous ad for Hamtronics. There is no reward being offered. *73* goofed! Our apologies to anyone who has been inconvenienced.

MEADVILLE PA
MAY 7

The Third Annual Northwestern Pennsylvania Hamfest will be held May 7 at Crawford County Fairgrounds, Meadville PA. Free admission. Flea market begins at 10 am. $2 to display — hourly door prizes — refreshments — commercial displays welcome. Indoors if rain. Talk-in 146.04/64 and 146.52. Details C.A.R.S., PO Box 653, Meadville PA 16335.

SUPERIOR WI
MAY 7

The Twin Ports Two Meter Club will hold its Second Annual Swapfest on Saturday, May 7, 1977, in the hall of the Duluth First Methodist Church from 11 am to 3 pm. Pre-registration and door prizes will be awarded. Admission is $1.00 in advance and $1.25 at the door. Selling space is $1.50 additional — $1.00 with your own table. Food available on the premises. Plenty of parking. Talk-in on 34/94. For flyers and/or tickets, contact Twin Ports Two Meter Club, c/o Libby Welsh WB9MLN, 525 Homecroft Court, Superior, Wisconsin 54880.

BINGHAMTON NY
MAY 7

The 18th Annual STARC Hamfest will be held Saturday, May 7, 1977 at Binghamton, New York. Take exit 71N from NY-17, go 3.8 miles north on Stella-Ireland Road. Flea market, tech talks, hourly door prizes. General admission $2.00/person. Banquet by pre-reservation at $6.00/person. Indoor exhibit space by pre-registration at $5.00 per table. Outdoor exhibit flea market space free. Talk-in 146.22/82 and 94/94. For details and reservations, contact STARC, PO Box 11, Endicott NY 13760.

GREEN BAY WI
MAY 7

The Green Bay Amateur Radio Club will hold its 2nd Annual Electronic Hobby Swap on May 7, 1977 at the Wisconsin Army National Guard Building, 800 N. Military, Green Bay, Wisconsin. Swap runs from 8 am til 4 pm. Admission $2.00; table space $2.00. Food, refreshments, entertainment, prizes, etc. For further info contact David Boyce WB9QYJ, 706 Mather Street, Green Bay, WI 54303, or Bob Heiser WA9SWX, 1547 Foeller Drive, Green Bay, WI 54302.

BIRMINGHAM AL
MAY 7-8

The Birminghamfest Amateur Radio Convention will be held May 7 and 8, 1977 at the Alabama State Fairgrounds, Birmingham and Rodeway Inn, Oxmoor at I-65 and Oxmoor Road. One of the country's largest flea markets, technical and operating forums, huge prize drawing, manufacturers' and distributors' displays, ladies' and children's activities. Booth display area will be offered free of charge to bona fide distributors, manufacturers, publishers, etc., on a first-come, first-served basis. Others may rent space in inside or outside flea market areas at a small charge. No admission charge. Prize ticket donations — $1. Talk-in 34/94, 3965 kHz. For booth display space, information, and reservations, write: Birminghamfest, PO Box 603, Birmingham AL 35201.

KEY WEST FL
MAY 7-8

The Second Annual Key West Conch-fest will be held May 7 and 8, 1977. $12 includes one dinner and admission to many attractions in the Key West area. Door prizes will be awarded. Reservations and room information available from Dennis Farr, 1831 Harris Ave., Key West FL 33040.

SANTA BARBARA CA
MAY 13-15

The 22nd annual West Coast VHF Conference will be held on May 13-15, 1977 at the Miramar Hotel on the beach in Santa Barbara CA. The event opens with registration at 6 pm Friday (May 13), followed by a full day of technical presentations starting at 9 am, Saturday. Pre-registration fee is $2 until April 30. After that and at the door, $3. Registration forms, hotel information, and further details may be secured by writing Dr. Overbeck at the Communication Division, Pepperdine University, Malibu CA 90265.

WARMINSTER PA
MAY 15

The Warminster Amateur Radio Club's "HAMMART," Flea Market and Auction will be held Sunday, May 15 from 9 to 4 at William Tennent Intermediate High School, Street Road (Route 132), 2 miles East of York Road (Route 263), Warminster, Bucks County, Pa. Registration $1, tailgating $2 additional. Talk-in on 147.69-09; 146.16-76 and 146.52. For further information write to Horace Carter K3ZAC, 38 Hickory Lane, Doylestown PA 18901.

IRVINGTON NJ
MAY 15

The Irvington Radio Amateur Club Hamfest, Flea Market will be held Sunday, May 15, 1977 from 9 am to 4 pm at the P.A.L. Building, 285 Union Ave., Irvington, NJ. The P.A.L. building borders the Garden State Parkway at Exit 153. Talk-in 34-94 and 52. Prizes and refreshments. Tables $3. For further information write Radio Club P.A.L., 285 Union Ave., Irvington, NJ 07111 or call Ed WA2MYZ 201-687-3240 evenings.

WEST LIBERTY OH
MAY 15

The Champaign/Logan Amateur Radio Club will hold its annual flea market on May 15, 1977, at the West Liberty Lion's Park, West Liberty, Ohio. Free admission. Trunk sales and tables $1.00. Door prizes. Talk-in on 146.52.

ROCHESTER NY
MAY 20-22

The Rochester Hamfest (combined with the New York State ARRL Convention) will be held May 20-22, 1977 in the Dome Center at the Monroe County Fairgrounds. The show will open at 9 am Saturday; closing will be at 5:30 pm. The show will reopen on Sunday 9:30 am and run until 5 pm. Eight by ten foot booths are available for only $100 each payable in cash only, in advance. Multiple booths are available at reduced rates: double $180; triple $250. For additional information contact E. Ashley Palmer K2EAW, 1776 Hudson Ave., Rochester, NY 14617 or call 716-338-2180 during working hours.

CADILLAC MI
MAY 21

The Cadillac, Michigan 17th Annual Swap-Shop will be held Saturday, May 21st, 1977, at the National Guard Armory, Cadillac, Michigan. Free parking, everyone welcome. Tickets $2.00. Talk-in on 146.37/97.

RAVENNA OH
MAY 21

The Hanna Hills Radio Club located at 5555 Newton Falls Road, Ravenna OH 44266, will sponsor an auction at the Survival Center Saturday, May 21, 1977. Flea market at 10 am; auction at 2 pm. Tickets at door $2. Bring your own flea market tables. Directions to QTH on 146.52 simplex.

LAKE DELTON WI
MAY 21

The 1977 ARRL Wisconsin State Convention will be held Saturday, May 21, 1977 at the Dell View Resort in Lake Delton, Wisconsin. From the south, take the Highway 12 exit, head north to the Resort. From the north, take the Highway 23 exit and go east to the Resort. Talk-in station WB9FDZ on 146.94 MHz. There will be ladies' activities, directional bearing and transmitter hunt, liars' contest, etc. For info and advance registration, contact Ken Ebneter K9EN, 822 Wauona Trail, Portage, WI 53901. This convention sponsored by the Yellow Thunder Amateur Radio Club, Inc.

VANCOUVER WA
MAY 21-22

The Fort Vancouver Hamfair will be held Saturday and Sunday, May 21 and 22 at the Clark County Fairgrounds, 7 miles north of Vancouver

on I-5. Sponsored by W7AIA, Clark County Amateur Radio Club, in cooperation with W7KYC, Portland Amateur Radio Club. Camping, contests, swap & shop, prizes, displays, and many other activities. Registration donation $3. Send registrations to Dorman Stafford W7ZDR, Registration Chairman, Fort Vancouver Hamfair, 3509 E 21st St., Vancouver WA 98661. Make checks payable to Fort Vancouver Hamfair. Talk-in on 2 and 75 meters.

PITTSBURGH PA
MAY 22

The 23rd annual Breeze Shooters Hamfest is Sunday, May 22, 1977 at White Swan Park, Parkway West, near the Greater Pittsburgh International Airport. Western Pennsylvania's largest ham event. Amusement park adjacent to site. Free parking. Contact WA3LUM, 311 Evergreen Ave., Pittsburgh, PA 15209.

TRENTON TN
MAY 22

The Humboldt Amateur Radio Club's Annual Hamfest will be held on Sunday, May 22, 1977 at Shady Acres City Park in Trenton, Tennessee. Flea market, prizes, ladies activities, etc. For further information contact Ed Holmes W4IGW, 501 N. 18th Ave., Humboldt, TN 38343.

EVANSVILLE IN
MAY 22

The Tri-State Amateur Radio Society is holding its annual hamfest on Sunday, May 22, at the Vanderburgh County 4-H Center in Evansville, Indiana. There will be food available, setup space, door prizes, grand prizes, and more. Bring your XYL, YL or OM, there will be fun for all. Talk-in frequencies are 75/15, 19/79 and 52. For further information please write TARS, Steven Harris, R-2 Box 81G, Mt. Vernon, Indiana 47620.

SANDUSKY OH
MAY 22

The Erie Amateur Radio Society will hold their annual Vacationland Hamfest on Sunday, May 22, 1977 at the Erie County Fair Grounds on South Columbus Ave., Sandusky, Ohio. Plenty of flea market tables @ $4 each. 8 acres for trunk sales. First grand prize is a color portable TV. Tickets $1.50 advance, $2 at gate. Flea market vehicles $1 each. Free transportation to Cedar Point Ferry Boat Docks. Call in on 52/52 FM. For further information or reservations write E.A.R.S., P.O. Box 2037, Sandusky OH 44870.

EASTON MD
MAY 22

The Third Annual Easton Amateur Radio Society Hamfest will be held on May 22, 1977, rain or shine, 10 am to 4 pm. This is the only hamfest held on the Eastern Shore of Maryland or on the Del-Mar-Va Peninsula. It's located 5 miles north of Easton, Maryland on US Rt. 50, at the Talbot County Agricultural Center. From the Baltimore or DC area, go across the Chesapeake Bay Bridge and follow Rt. 50 East for 21 miles from the bridge. Exact location is between mile markers 60 & 61. Hamfest signs will be on Rt. 50 both north and south, and talk-in on 52 and 146.445-147.045 repeater in Cambridge. Some tables available, refreshments, and prizes. Donation $2.00 with an additional $2.00 for tables and tailgaters. For further info contact Robert L. Roberts, Jr. K3ONU, PO Box 781, Easton MD 20601 or phone after 6 pm 301-822-0943.

WEBSTER MA
MAY 22

The Eastern Connecticut Amateur Radio Association will hold their 4th Annual Flea Market on May 22, 1977 at Point Breeze Rest., Webster, MA. Time will be from 10:00 am to whenever. Dealer fee will be $5.00, admission $.50 per person. Free parking. Take Rt. 52 to Exit 1 in Webster then south on Rt 193 one mile. Look for signs. Talk-in on 52 direct, 16-76, 10-70, 825-225 channel 14.

WABASH IN
MAY 22

The Wabash County Amateur Radio Club's 9th Annual Hamfest will be held Sunday, May 22, 1977, at the Wabash County 4-H Fairgrounds in Wabash, Indiana. Large flea market (no table or setup charge), technical forms, bingo, plenty of parking and lots of good food at reasonable prices. Admission is $2.00 for advance tickets, $2.50 at the gate. For more information or advanced tickets write Bob Mitting, 663 N. Spring St., Wabash, IN 46992.

DURHAM NC
MAY 28-29

The DURHAMFEST will be held May 28-29, 1977 at the South Square Shopping Center in Durham, NC. There will be a two-day flea market, fantastic prizes, seminars, bingo and shopping held for the family. Talk-in on WR4AGC: 22-82 and 222.34-223.94. For further information contact Durham FM Association, Box 8651, Durham, NC 27707.

BURLINGTON KY
MAY 29

The Kentucky Ham-O-Rama will be held Sunday, May 29 (Memorial Day Weekend) at Boone County Fairgrounds, Burlington, Kentucky. 10 minutes south of Cincinnati, Ohio, 2 miles from I-75 South, Burlington exit. Prizes, exhibits, flea market. Info: NKARC, PO Box 31, Ft. Mitchell KY 41017. Tel. (606) 331-4922.

MINNESOTA
JUNE 4

Amateur Fair '77: Dakota Division's largest Swapfest for amateur radio operators and computer hobbyists. Saturday, June 4th at the Minnesota State Fairgrounds. Free overnight parking for self-contained campers. Talk-in on 16/76 and 52/52. Selling from your car or from our tables. Some "undercover" space available. Presented by the Twin City FM Club. Prizes include: Wilson HT, Bird Model 43 Wattmeter, and much more. Admission $2. For advanced space reservations, tickets or information call Gary at (612) 644-4488.

HERNANDO MS
JUNE 11-12

The Chickasaw Amateur Radio Association, Inc., "CARA," of Hernando, Mississippi presents its annual Tri-State Hamfest June 11-12, 1977 at the National Guard Armory in Hernando, Mississippi, 20 miles south of Memphis, TN on Interstate 55. Plenty of parking area with camping sites. Tables available at $2.00. Doors open 12:00 to 6:00 Saturday, June 11th, and 8:00 to 4:00 Sunday, June 12th. Prizes, food, and beverages. Talk-in on 146.31/91, 146.52, and 3987.5. For further information write CARA, PO Box 2, ATTN: R. Gates, Hernando MS 38632.

NEWBERRY MI
JUNE 12

The Tahquamenon Amateur Radio Society swap and shop will be held Sunday, June 12, 10 am to 6 pm at the Pentland Township Hall, 3 miles south of Newberry and 2 miles west

CB to 10 -- A Legal Alternative

-- part II: conversion data

How about a brand new DX transceiver that's rock stable, plugs into your cigarette lighter, and tunes 23 frequencies on 10 phone for less than $30? Of course, there are a couple of drawbacks — power output 4 Watts, and an emission type the sideband guys call Ancient Modulation — but those problems are hardly worth mentioning. Just ask any old-timer who worked the peak of the '46-'48 sunspot cycle. You *can* do wonders with just a few Watts on 10 phone, and the technical specs on the $29.95 transceiver make it a superior performer to what was available in 1946.

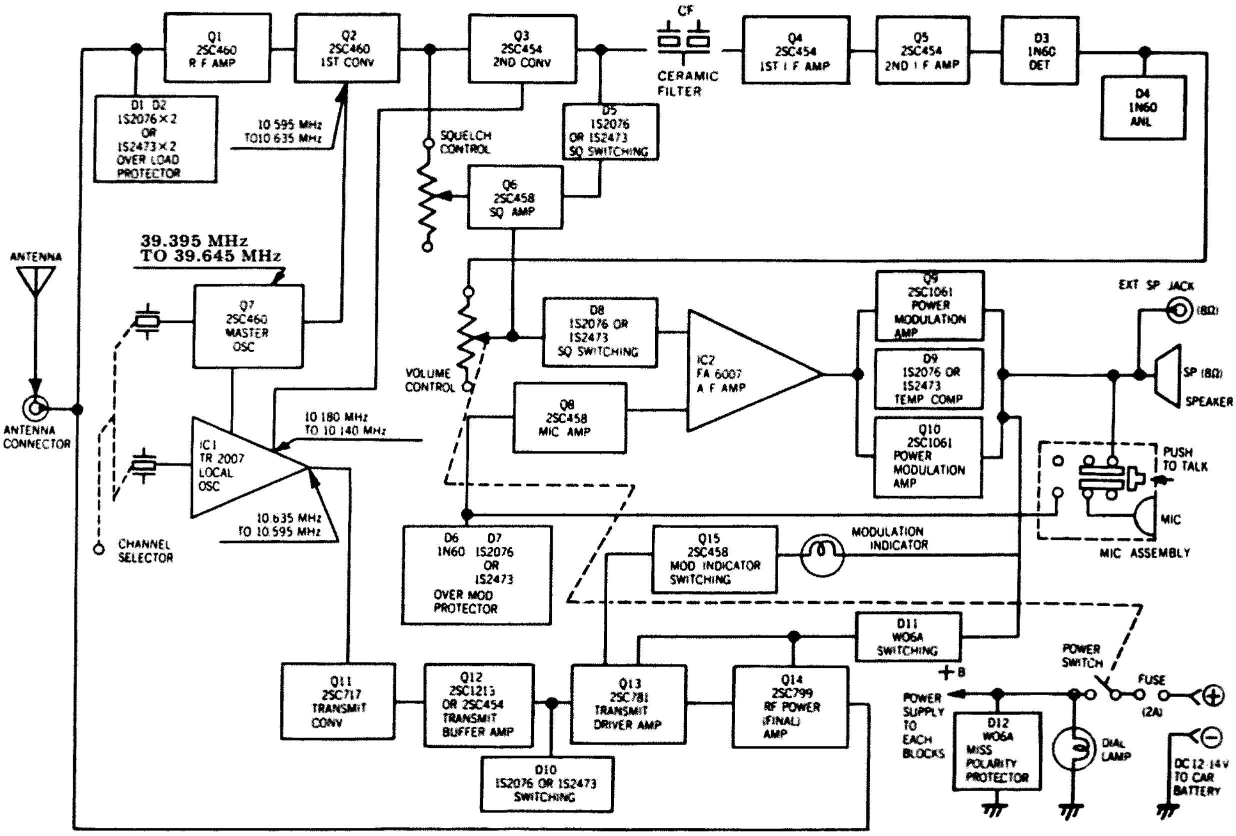
For several years, I've been watching the want ads and going to swap meets in search of the perfect junk CB rig. I had plans for picking up one for just a few dollars, changing a few crystals and — presto — getting on ten phone quick and dirty. I never really found what I wanted for a cheap enough price (CB SSB was always too expensive!) and I soon lost interest. And besides, I was busy getting onto two meter FM, plus I didn't want to give up working the low bands on CW or SSB. All of that was before the FCC approved 40 channel CB for use after January 1, 1977. When a lot of manufacturers started dumping their older model 23 channel sets on the market at bargain prices, I got reinterested in recycling a CB radio up onto 10 phone. I watched the ads and finally bought a J. C. Penney transceiver model 981-6201. It is a quality piece of gear that usually sells for twice the price. There are 2 ICs, 12 diodes, and 15 transistors in a double conversion receiver and AM transmitter configuration. The manufacturer claims 0.5 microvolt sensitivity at a 10 dB signal plus noise to noise ratio. Power output from the 2SC799 rf amplifier is listed at 4 Watts and the spec sheet advertises 90% modulation. Loaded, the transmitter draws 1.4 Amps at up to 13.8 volts (easily obtainable from the cigarette lighter in your car or from a small ac supply). The rig has a built-in squelch circuit, but is not equipped with an rf tuning indicator or receiver S-meter.

10 Meter Channel	Frequency (MHz)	Master Oscillator Frequency
1	28.76	39.395
2	28.77	
3	28.78	
4	28.80	
5	28.81	39.445
6	28.82	
7	28.83	
8	28.85	
9	28.86	39.495
10	28.87	
11	28.88	
12	28.90	
13	28.91	39.545
14	28.92	
15	28.93	
16	28.95	
17	28.96	39.595
18	28.97	
19	28.98	
20	29.00	
21	29.01	39.645
22	29.02	
23	29.05	

Table 1. Frequency coverage of the $29.95 DX transceiver.

When the Citizens Band was created in the 1950's, the early rigs used 23 pairs of crystals to tune both transmit and receive on all 23 channels. Converting one of those rigs to 10 phone would cost a small fortune to crystal up, but I was prepared to pay it until Norm Lefcourt W6IRT mentioned that the newer CB rigs use crystalplex, replacing the old 46 crystals with 14 new crystals and still covering all 23 channels. Norm pointed out that by replacing the six master oscillator rocks, I could cover 23 frequencies simplex on the 10 meter band with just a little tweaking of a few L/C circuits. W6IRT, WA6QPL, K6JUA, others and I all started working on the conversion. K6HY, K6LJJ, and WB6QKF helped with advice.

It sounds pretty easy, but there was a problem — deciding on which frequencies on 10 phone to use. The phone portion of the band is gigantic when compared to the other HF bands, and we wanted to pick a segment where there would be some activity. We didn't want to cause difficulties for other services, yet at the same time we wanted to stay near the low end so that retuning from the CB frequencies would not require a rewinding of coils. After an awful lot of discussing on the landline and two meter FM, we decided to stay away from both the very top end of the 10 phone segment (because of OSCAR) and from the very bottom end, too (because of the SSB DX activity just above 28.5). We finally settled on a starting frequency of 28.76 MHz for channel one, with the other 22 channels tuning upward from there. The decision was based on two practical considerations: First, the pres-



ence of the "10-10 club" net on 28.8 (our channel 4) could tell us very quickly when the band is open, and second, because many home QTH rigs only tune a single 500 kHz portion of the 10 meter band, choosing a frequency outside that segment would mean having to do without a very important piece of test gear – the station receiver.

The first 23 CB channels start at 26.965 and end at 27.255. Channels 1, 2, and 3 are 10 kHz apart, but there are 20 kHz between channels 3 and 4. Channels 4, 5, 6, and 7 are ten kHz apart, but between 7 and 8 there is another jump of 20 kHz. The cycle keeps repeating itself every fourth channel until channel 22, which is 10 kHz higher than channel 21 but 30 kHz lower than 23.

The J. C. Penney rig that I bought and W6IRT's Publicom #1 use six master oscillator crystals (37.600, 37.650, 37.700, 37.750, 37.800, and 37.850), four transmit crystals (10.635, 10.625, 10.615, and 10.595), and four receive (10.180, 10.170, 10.160, and 10.140). On transmit, the rig mixes the master oscillator with the transmit crystal (37.600 minus 10.635 is 26.965 – CB channel one). On receive, the receive crystals are the first i-f conversion frequency and the second i-f operates at 455 kHz. Image problems are minimized by the double conversion i-fs.

The Conversion

To begin with, you need new master oscillator crystals. The J. C. Penney rig uses six – if you want to be able to tune all 23 channels on 10 phone, you have to replace all six. If you only want four frequencies, replace only one master oscillator crystal; if you want to tune eight, replace two, etc. Not all of the crystalplex rigs use the same master oscillator frequencies – some operate in the 16 MHz range – so be sure to check the frequencies in your rig before you go out and buy new rocks. Both Norm and I are just replacing two master oscillator crystals to see how the eight channels work. But, eventually, we both plan to be outfitted with all six crystals and full 23 channel 10 meter coverage. Our new channel designations and crystal frequencies are spelled out in Table 1. Those are the frequencies we are using (along with about 30 other guys in Southern California). When you crystal up, use the same frequencies so we'll all have someone else to talk to. We will continue the CB channel designations (that saves changing the dial) so that our lowest frequency is channel one and our highest is channel 23.

After changing crystals (and a word of warning there – most master oscillator crystals are wire type and must be soldered in; BE CAREFUL!), hook the rig up to a 12 V dc supply and a suitable dummy load antenna. We found the receiver sections worked well enough so that tuning up only required peaking the rf and first mixer stage coils for maximum band noise. Transmitting is a little more complicated, but not impossible. If you don't have a voltmeter, use some kind of relative power output indicator (an swr bridge, a light bulb, etc.). Peak the coils in the transmit stage starting with the master oscillator. You don't have to peak the coil for the transmit crystals, because they still put out in the 10.600 MHz range. Peak each succeeding output stage for maximum indicator reading. If you have a voltmeter, connect it to the output of the transmit driver stage, then peak the lower stages for maximum reading. Then peak the final with some kind of power output indicator. The funny thing about the CB rigs we bought is that they all came with full and complete tune-up instructions – even though CBers aren't supposed to even touch them with a screwdriver.

Antennas: Most of the CB radios are designed for 50 Ohm output and most of the CB antennas sold are vertical-

ly polarized. Polarization probably won't make any difference on the real long haul skip, but for working ground wave with others in your area, it makes more sense to install a vertical antenna. That's what the mobiles are using anyway, and a rooftop groundplane for the home QTH is only 8 feet tall. After seeing what some of those yo-yos on 11 meters are using, I would say it won't take an awful lot to be able to get out.

The $29.95 transceiver is a good club project. If you can't find one on the market, hit the swap meets and check the ads in the local papers; you may even be able to get a better price by buying one from a disgruntled CBer who gave up trying to punch through the QRM. If you are big on modifications, I'd like to hear about them (or see them in print in case I want to try one of them). Here are a few I have in mind: A small VFO that will fit inside the transceiver case and plug into one of the master oscillator crystal sockets; a low cost linear amplifier capable of 15 to 20 Watts output; an alternate conversion for six meters or one for the low power DX guys who want to work 15 CW; a slider for receiver and/or transmitter offset tuning; a BFO; a sideband adapter; or maybe a transceiving converter to other bands.

Look for me on 10 phone. I'll be listening on channel 4 — 28.80 MHz. If I hook up with somebody, I'll QSY up or down to continue the contact. If 28.80 is busy, I'll hang out on channel 3 (28.78). How about you? If we all use the same "channels," it'll make it a lot easier to work 10 phone. If you hear me on though, don't give me any of that "... Breaker, Breaker, this is your old good buddy, got time for a 10-7 ...?" baloney. I heard all of that I could stand while I was waiting for my crystals to arrive!!! ■

All-Electronic SELCAL

- - uses a UART for versatility

Anthony Sperduti WB2MPZ
4740 Newton Rd.
Hamburg NY 14075

There have been a few articles on the merits of the selective call (SELCAL) circuit. All of them have been on the use of the Model 28 stunt box. To those of you who are unfamiliar with the 28 stunt box, I will go over it a bit. It is a mechanical arrangement of fingers that are spring-loaded and press against the parallel code bars on the 28 machine. The code bars have slots in them, and when the slots are properly lined up to a stunt box finger, that finger will slip into the slot and provide you with a mechanical function of the machine to perform an operation such as line feed, carriage return, or almost anything you want it to do. It also will operate a switch that you must put on top of this finger. When the finger moves forward, it will operate this switch. The machine has 42 slots for these fingers in the stunt box, which is located between the paper roll and the printer. If you fully load one of these machines up with all 42 code bars, it gets a little crowded, to say the least. It also can get to be very expensive, as these little things cost around 2 bucks each. Now you have to get switches for each one and then run all the wiring to the switches. If you want to do logic with the switches, you will have to build up a heck of a lot of relays to do your logic work for you. For example, if you want a circuit to operate when you have 7 characters in a row, you must first have seven of these bars in your machine that have the characters you want coded on the ends – that is, you either buy them for your callsign or you buy the ones that have all the fingers on them and break off the ones you don't want. Once you set it up, you have had it; you cannot change anything. What I am trying to get over is that it can get expensive and really complicated with a fully loaded stunt box. If you don't have a machine with a stunt box, you can't do it. After playing around with this idea, I decided to come up with an electronic stunt box that could be used with any machine and could also be changed to any character combination that I wanted. Since hams like to have names for these circuits, I will call it the ESB-1, that is, Electronic Stunt Box One. This little circuit will do everything that any mechanical stunt box can do and do it better, faster, cheaper, and easier.

Since by now almost all RTTY people know what a UART is, I will not go into the merits of one and how it works. You will get an added benefit using the SELCAL with a UART, as not only does it enable you to have an electronic stunt box, but it also will help in cleaning up the received signal for better copy. I will go over the circuit to explain how it operates.

The UART is a GI AY5 1013 that converts the incoming teletype signal to a parallel signal. That is, it receives the serial signal and puts the bits out on five separate lines. The UART has been wired to copy a 5 bit code (Baudot). The second half of the UART now converts it back to serial again so that it can drive the TTY machine loop. The five bits are on pins 12, 11, 10, 9, and 8. Pin 12 is the first bit and 8 is the fifth bit. Note that these five lines are wired to a pair of 9311 (74154) one of sixteen decoder/demultiplexers. Pins 20, 21, 22, and 23 of the 9311s are the address lines of these chips. Pins 18 and 19 are the enable pins. Pins 1 through 17, with the exception of pin 12, are the output pins. The outputs are all active low – that is, when they are addressed, they will go low; all other times they will be high. Only one output pin at a time can go low, and then only when that chip is enabled by pulling both enable pins 18 and 19 low. In this circuit, I do not pay attention to what case the machine is in, as it can't really tell. I will assume that it is always in lower case letters. Check the truth table in Table 1 and you will see what lines address the output pins. For example, if pins 20, 21, 22, and 23 are all low, and the two enable pins are low, output pin number 1 will go low. If pin 23 is high, and 22, 21, and 20 are low, and both enables are low, output pin 2 will go low. This is a BCD code, with pin 23 being the least significant bit and 20 the most significant bit. Bit number 5 from the UART is connected to one of the enable pins (18) of num-

Table 1. Truth table, 9311/74154.

ber 1 9311 and then inverted through the 7404 to pin 18 of the other chip. What this does is address chip number 1 when the fifth bit from the UART is low and address chip number 2 when the fifth bit is high. The DAV (data available) output of the UART is connected to the other enable pin (19) of both 9311s.

Now the data is put on the parallel lines from the UART; this addresses the proper chip for which character you want from it. Now the DAV line from the UART goes low, enabling the second enable pin on the 9311, telling it to decode, as data is on the line and it is addressed. This will put a low level on one of the output pins of that chip, depending on which character is being received by the UART.

The DAV line also ties to the 7404 and the 7400, pin 12. The 7404 inverts the DAV signal and clocks the parallel lines into the transmit part of the UART and also feeds back into the UART RDAV (reset data available line). This will cause the DAV line to go high and inhibit the 9311s. Now the output that went low on the proper 9311 will go high. You can see that this gives us a fast pulse out of the 9311s that is just long enough to trigger the 7473 flip-flop that is tied to that line. Table 2 shows the Baudot code that is related to the parallel lines on the output of the UART.

This SELCAL is designed to work with the ST-5 or ST-6 terminal unit. In the May issue of the *RTTY Journal*, Irv Hoff has a circuit of how to modify the ST-6 to use the UART. All it consists of is the removal of the 2200 Ohm resistor that is connected to the base of the driver transistor MJE 340. Fig. 1 is a copy of this circuit modification. Connect the output of the op amp slicer to the input of the SELCAL pin 4 and then the output of the SELCAL pin 6 to the base of the drive transistor. The input to the SELCAL keys the 2N706, gets inverted by the 7404, and drives the UART through pin 20. The pulses always get through the UART and come out pin 25. This is again inverted by the 7404 and tied to one input of the two input 7400 NAND gate. The other input of this NAND gate is connected to the Q output of flip-flop number 4B. This output is low so that no pulses will get out of the SELCAL and the magnets will be held in the mark hold mode. Transistor Q1 is 2N706 and it monitors the autostart relay in the ST-6. Pin 15 of the SELCAL is connected to the collector of Q5 in the ST-6. When the ST-6 relay is not picked up, you will have a positive 12 volts coming in and this will turn on Q1. The collector of Q1 will go low and hold flip-flop number 4B reset. This puts pin 9 of this flip-flop low and keeps the output and gate 7400 from passing any data to the keying transistor of the ST-6.

When the ST-6 autostart relay picks up, the collector of Q5 in the ST-6 will go to negative 12 volts. This turns off transistor Q1 in the SELCAL and the collector of this transistor now goes positive and takes off the reset hold on the number 4B flip-flop. Data will still not get through the SELCAL as the Q output of the flip-flop is still low until it is toggled. You will note that the collector of Q1 was not only holding the reset of flip-flop 4B, but also the reset on flip-flop number 1A through the two 7408 AND gates. Flip-flops 1, 2, 3, and 4 are all connected in series so that the flip-flop ahead of it is holding its reset low and therefore its Q output will be low. When in this mode, no pulses will be able to toggle any of the flip-flops. When transistor Q1 collector goes high, it removes the reset from flip-flop number 1A. The DAV line from the UART cannot pulse the 7490 counter as it cannot get through the 7400 NAND gate, because flip-flop 1A is holding one of the gates low. On the reception of the first FIGS character, flip-flop 1A gets toggled, the Q output goes high, and now will let the DAV line toggle the counter. The Q output also removes the reset from flip-flop 1B, enabling it to be toggled if the next character is an A. The Not Q output of flip-flop 1A is tied back to the K input and prevents it from being toggled anymore if you send another FIGS. It also removes the reset on the 7490 counter so that the pulses from the DAV line will now increment the counter each time the DAV line goes high. Now follow the chain down the flip-flops and you will see that each character in the string of FIGS A, S, I, A, O, and U will toggle flip-flops 1A, 1B, 2A, 2B, 3A, 3B, 4A, and finally 4B. Flip-flop 4B will turn on the LED, showing you the SELCAL is active, and puts a positive on the 7400 NAND gate, allowing the data to get out of the SELCAL, key the ST-6 driver transistor, and print on your machine on the very next character after the U.

Let's go back to the counter. The 7490 counts the characters that come in after the FIGS is received. This is

so that you must make ASIAOU in six characters or the whole chain of flip-flops gets reset via pins 8 and 9 of the counter, through the 7400 NAND gate and the two 7408 AND gates. You must now start all over with the FIGS to get the chain going again. You must send these 7 characters in a row and in the proper sequence in order for the SELCAL to operate. If it were not for the counter, the chain would sit there and just wait for the characters to come through. Whenever it did sense these seven in sequence (even though you had hundreds of characters in between the valid ones), it would turn on. The NE555 timer is just set up for a clock for the UART. It is adjusted for 32 times the baud rate that you want to receive and then flip-flop 5A divides it by two so that it is a symmetrical clock pulsing the UART. The UART wants to get pulsed 16 times the baud rate you are receiving. I run my machine at 100 wpm or 75 baud. 75 times 16 is 1200, and that is my clock frequency at the UART. The simple little power up circuit using diode D1, resistor R4, and capacitor C3 insures that every time I turn the power on the SELCAL, it will reset all the flip-flops. The way it works is that when power is first turned on, all the gates and flip-flops will come up to power before the gate on pin 5 of the 7408 AND gate. This is due to the fact that the capacitor tied to this pin is short circuited until charged and will hold this pin low long enough to reset the flip-flops. You can fool this circuit if you turn the power off and then on again before the 100 uF capacitor has a chance to discharge. Once the SELCAL is turned on, it will not shut off until you turn the power off, push the reset button, or the ST-6 autostart relay drops out. Any one of these will reset all the flip-flops and now you will have to do the whole thing all over again.

A friend of mine asked me if I could come up with a circuit like this that could be easily changed to any 7 characters you wanted, be simple, and above all, be reasonable in price. I looked up the price of all the chips and came up with a fantastic price for everything (including the UART, resistors, and capacitors) – less than $35.00. This does not include the power supply or the board to mount the chips and the sockets for them. I hope to lay out a PC board and make it available for somewhere around $8.00, depending on my costs. The power supply needs a good regulated 5 volts at 300 mA and negative 12 volts at 10 mA. I am sure this will not strain any power supply that you are using for your ST-6. This circuit can be expanded to any amount of characters that you would want by simply adding flip-flops and changing the counter to what you would want to count. A turn-off of 4Ns is incorporated by switching in the other flip-flops and separate counter so that when you get four Ns, you pulse the reset and turn off the chain of flip-flops. I am sure that this circuit will save many rolls of paper that get tossed out of your machines when you are in the autostart mode and not home and some CW station happens to get your machine going with line feeds. I monitor the Navy Marine Corps MARS frequencies and was shocked one time when I came home from work and heard a RTTY station just sending out test pulses; every one of them to my machine was a line feed. I must have

Fig. 2. ESB-1. Parts list: 1 – UART; 2 – 9311/74154; 1 – 7400; 1 – 7404; 1 – 7408; 7 – 7473; 2 – 7490; 1 – 555; 2 – 2N706; 3 – 1N914; 1 – LED.

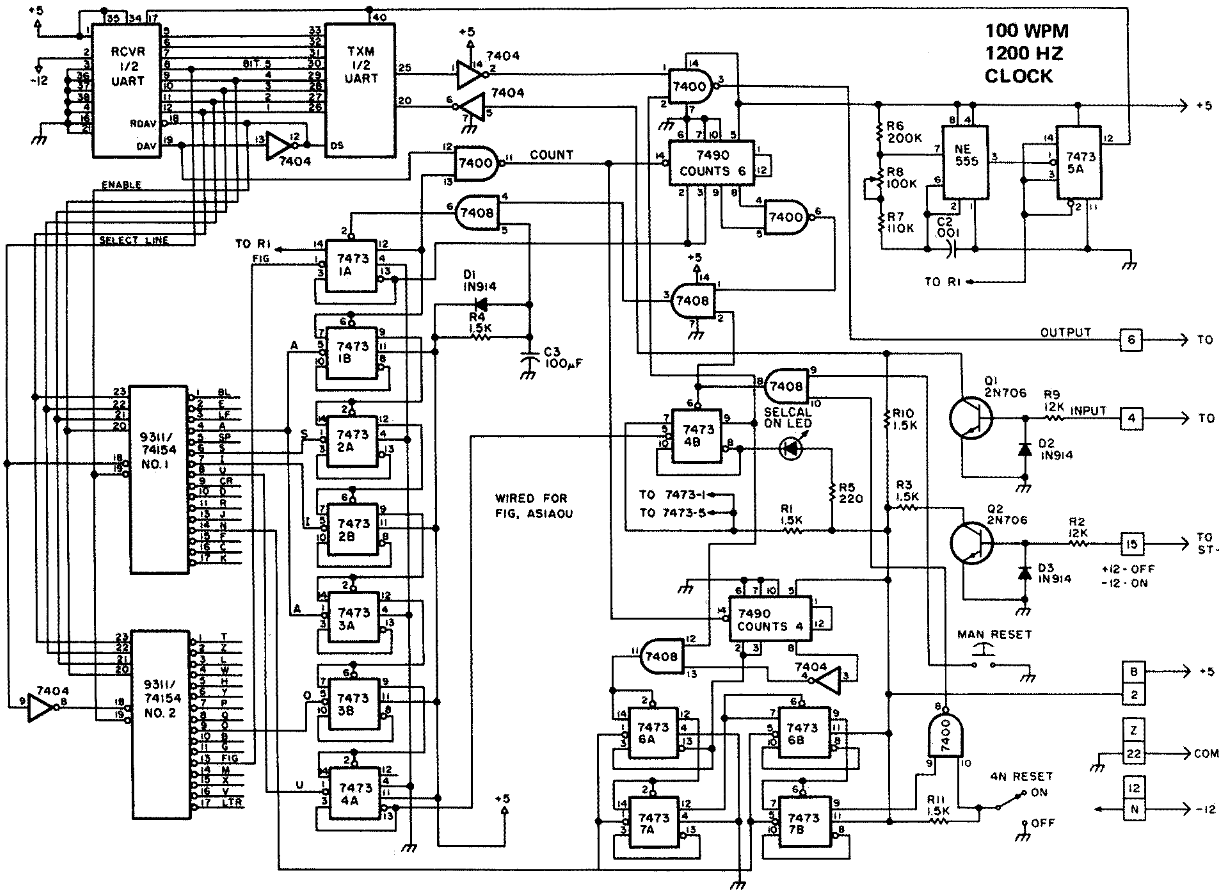

Table 2. Truth table, 5 bit TTY code.

rolled up 50 feet of paper off the floor back on to the spool. My wife would not go near the machine for a while, as she thought the dumb thing was going to blow up. This circuit should make autostart stations feel a bit more at ease knowing that their machine is not going to print unless it hears their callsign or any other combination of 7 characters that they want to choose. ■

Corrections

I read the article "Have You Used a Triac Yet?" in the October '76, *73 Magazine*.

You seem to have conveyed the wrong notion of holding current.

This current is *not* a gate current. It flows from anode 1 to anode 2.

Once the gate current has triggered anode-anode current, one could cut its gate current to zero (open circuit) and anode current would continue to flow.

The only way to stop it is to increase the resistance in series with the anode-anode supply, until the current flowing drops below a certain critical value. *This is the holding current.*

More usually, one removes the supply voltage by using an ac or a pulsing dc source.

Michael Murphy VK6ZCX
Wembley Downs
Western Australia

I've noticed a few corrections which should be made to my article ("Build a Counter for Your Receiver") in your October, 1976, issue. In Fig. 2, the output of the 8T98B should be connected to the following input and the 1k resistor, but not to ground. In Fig. 8, the emitter of the first HEP15 should be connected to the junction of the 2 1500 pF capacitors, but not to its base. The connection dots indicating +5 V connected to pin 14 of two of the 7490s should be removed. Relative to the power supply design shown in Fig. 9, I found that removing about 7 feet of wire from the secondary of the recommended power transformer allowed the regulators to run much cooler. This seems to be an ideal way of obtaining low cost power transformers for home computers.

Jack Regula WA3YGJ
Freeville NY

Please note the following corrections to "Mobile Smokey Detector" (Holiday, 1976):

1. In Fig. 2, the circuit diagram, the resistor connected to pin 14 of the CD4011A integrated circuit is 100 Ohms. It is a decoupling filter.
2. The location of the detector crystal and modulator diode are in conflict in Figs. 2 and 3. The locations in Fig. 3 are correct.
3. The tips of the diodes shown in Fig. 3 appear to touch the inside wall of the circular waveguide, which is correct, but part of the drawing was left off, to indicate that sleeves which make good electrical contact should be installed. These may be constructed from brass pipe obtained in model shops. The pipe has an inside diameter which tightly slides over the diode tips.
4. Please do not plan on getting on the X band frequency or, for that matter, on any frequency without a license. The implication that a license might not be required was the editors', not W1SNN's.
5. Parametrics 400075 Schottky diodes may be purchased from Parametrics, Inc., of Winchester, Massachusetts, or Microwave Associates, of Burlington, Massachusetts. Both of these manufacturers have a minimum order requirement, and may not be too sympathetic to selling pairs of diodes. K1NAY, 25 Westfield Road, Natick, MA 01701, has a sales schedule for pairs of these diodes, which may help. 1N23E diodes will work well in both places, but care must be used in biasing and with the switching levels. Use them as a last resort.

Stirling M. Olberg W1SNN
Waltham MA

The first two articles read after scanning the January, 1977, issue were: "Dirt Cheap Regulation," and "Behavior Mod for the HM-102."

In the first article, the author did not follow his own parameters for criteria when he loaded the supply to 1.2 A for 30 mA residual ripple. With any kind of Beta on the two transistors, the regulation should be better than that. Also not mentioned is that the emitter of T1 has residual ripple (output ripple) which is in phase with the base ripple and so is degenerative, further reducing ripple. The C to reduce ripple in the regulator would be far more effective and smaller (cheaper) if placed at the base of T1, instead of as illustrated before the isolating resistor. Of course, if current limiting is also used, some isolation from T1 base would be advisable after C. This convenience and security can be easily secured by a small value resistor in the negative return lead and an NPN transistor with collector connected to T1 base. Also, it might be mentioned, since we are going to the junk box, that zeners and conventional diodes, both germanium and silicon, can be combined for precise values. The literature also provides the information so that the combination will be less temperature dependent.

As for the fine article on modifying the HM-102-1, there is an error in the drawing. Some of the boys, quick with the soldering iron, might proceed at once, looking at the manual and the drawing. The new lead (white) to R4 does not go to pin 5 of SW2, but remains at pin 4. The red lead should be shown from B to pin 5.

Frank C. Ruland
Oklahoma City OK

With regard to my article "Digital Autopatch" (April, 1977), I would like to point out the following:

1. "Touchtone" is a registered trademark of AT&T.
2. In the caption for Fig. 6, the following should be deleted: "R5, Q3 not used. Highest R = 31; highest C = 20".
3. On the third page of the article, column 1, line 10, should read, "to 7. The 74193 loads a '1' ".
4. In Fig. 9(b), "17" should read "L1". Please note that the configuration for the 2N3904 transistor was inadvertently omitted (although the pads are shown).

Ham Help

The Laundale Amateur Radio Club, a newly formed youth oriented organization, seeks your assistance in acquiring equipment. We need all types of usable equipment (VHF antennas, keyers, matchboxes, etc.) to get our members on the air. We are lacking funds, so a nice low price tag or a donation would be well appreciated. Help a young ham and send your info to:

Dennis J. Gazak WA3SZD
President, Laundale ARC
321 Stevens Street
Philadelphia PA 19111

Will be glad to help any County Hunter with Dukes County, Mass. during 1977 on 80-40-20. Just drop me a note for a sked.

Duncan Kreamer W1GAY
Box 637
Vineyard Haven MA 02568

I have an HW-16 CW transceiver and would like to operate it on the twenty meter CW band. I have heard there is a modification to change the 15 meter portion to the 20 meter portion, but am unable to find any info on it. Can someone help?

Alvin S. Koslofsky WB2CUP
2105 Rockaway Parkway
Brooklyn NY 11236

Wanted: a small lightweight QRP transmitter for 40 meter CW operation, 12 V dc or ac line okay. Write giving full particulars. Needed by June.

James Kates WB8TCC
360 North Hubbard Hall
Michigan State University
East Lansing MI 48824

I would like to get in touch with someone who knows his stuff on the Central Electronics 100 V transmitter. I'd like to try for repair advice by mail, or I'll phone. Alternatively, is there a commercial repair outfit who could handle it within a reasonable drive of North Jersey? Thanks much for any help.

Joe G. Koosman K2GFH
54 Brookside Terrace
North Caldwell NJ 07006

Could you show a circuit diagram of an 80/40 meter receiver suitable for CW communications? It should have selectivity.

Benjamin Diaz, Jr. WB4VEZ
2870 SW 123 Ct.
Miami FL 33175

Try "Novice Q & A" for the receiver tips, and January, 73, pg. 160, for a simple transmitter. — Ed.

I would like to appeal to your readers for technical advice on converting a Hammarlund FM 50a commercial transceiver to 2 meters. I am especially wondering about the 1st local oscillator in the receiver section.

Steve Royer
114 Sunset Pt.
Greenville FL 62246

Need help in designing and finding parts (ICs, etc.) for a solid state crystal-calibrated signal generator 3-30 MHz and FM 88-108 MHz and crystal-controlled 19 kHz, 4.5 and 10.7 MHz.

Ford I. Secrist WA3CWZ

on highway M-28. Refreshments at the site, ample parking, campsites available at a nominal fee. Reg. $2 at the door. Drawings and door prize. Many free family passes for tours in the famous Tahquamenon area. Many other prizes. Talk-in on 25-85, 28-88 52 & 94 simplex. Correspondence W8GBR.

AKRON OH
JUNE 12

The Goodyear Amateur Radio Club of Akron, Ohio will hold its 10th Annual Hamfest and Family Picnic on June 12, 1977 at Wingfoot Lake Park between the hours of 10 am and 6 pm. The park is located southeast of Akron on County Road 87 near Route 43. Ample parking, rain shelters, picnic facilities, kids' play areas and refreshment stands. The flea market/swap shop space is free with the admission ticket. Gear displays, prizes, etc. Sorry — no overnight parking or swimming. Mobile check-in on 04/64. Family donation $2 advance, $2.50 at gate. For more info contact Don Rogers WA8SXJ, 161 S. Hawkins Ave., Akron, Ohio 44313. Phone: (216) 864-3665.

SANTA MARIA CA
JUNE 19

The Satellite Amateur Radio Club is sponsoring its annual Santa Maria Amateur Radio Picnic and Swapfest Sunday, June 19, 1977 beginning at noon, at the Newlove-Union Oil Picnic Grounds on Orcutt Hill (watch for the sign marking the turn-off one mile south of Clark Ave. on U.S. 101). Swap tables available at $3 each. Santa Maria Style Barbecue to be served at 2:30 pm. Talk-in on 146.52 and 7280 kHz. Many prizes. Tickets $5.00 adults, $2.50 children. For advance orders, send checks to Santa Maria Swapfest, Post Office Box 1031, Nipomo, California 93444. For further info contact Satellite Amateur Radio Club, PO Box 1615, Vandenberg Air Force Base, CA 93437.

PORTAGE IN
JUNE 19

The Lake County Amateur Radio Club's 3rd annual hamfest is June 19th at the Isaac Walton League in Portage, Indiana. (Take I-94 to Ind. 249 exit, then north on Ind. 249 ½ mile.) Tickets: $1.50 advance, $2.00 at gate. Write: Herbert S. Brier W9AD (W9EGO), 409 S. 14th St., Chesterton IN 46304.

JACKSONVILLE IL
JUNE 26

There will be a hamfest held in Jacksonville, Illinois June 26, 1977. Same place as last year. Talk-in 146.40/147.00 WR9ACS. For further information contact (after April 1st) Box 271, Jacksonville, IL 62651.

CUMMINGTON MA
JULY 9-10

The Northern Berkshire Amateur Radio Club Hamfest will be held July 9th and 10th at the Cummington Fairgrounds, Cummington MA. Free overnight camping, tech talks, demos., and dealers. Flea market $1. Admission $3 with XYL $5, advanced $2 and $4. For information write Hildy Sheerin WA1ZNE, 79 Greylock Ter., Pittsfield MA 01201.

OAK CREEK WI
JULY 9

The South Milwaukee Amateur Radio Club Swapfest '77 will be held Saturday, July 9, 1977 at Shepard Park (American Legion Post #434), 9327 South Shepard Avenue, Oak Creek, Wisconsin. Activities begin at 7 am and will run until about 5 pm.

NEVER SAY DIE

... de W2NSD/1

EDITORIAL BY WAYNE GREEN

LOST FREQUENCIES

The Jack Anderson column made a big deal out of how many frequencies amateurs have, while carefully skirting a more realistic evaluation of the situation. We're far enough into the space age now so that it should be clear to just about every active ham that while we can always have fun on the low bands, the opportunities of the UHF ham bands via satellites would make possible a communications system far beyond anything imagined in the past.

A series of synchronous satellites would permit several million hams to make contact at any time with any one or group of other hams . . . anywhere in the world. This, as the space age came upon us, was the real future that we had ahead. We were beginning to think in terms of getting to work on experimental UHF stations with signals strong enough for satellite work up in the GHz bands.

Then came the 1971 ITU space conference in Geneva . . . we were represented there by the ARRL. We went into that conference with about 237,254.77 MHz of amateur allocations for satellite use and we suffered a slight loss. Perhaps you read about it in the fine print in the back of *QST*. The ARRL team came back to announce that we had lost 237,247.27 MHz of satellite frequencies . . . with little hope of ever recovering the lost frequencies in the future. That's right — we went into the conference with 237,254.77 MHz and came out with 7.5 MHz.

When you consider that few of the frequencies above 500 MHz hold much promise for us if we can't use them via satellite, perhaps you can appreciate the magnitude of the loss.

There I go being anti-ARRL again . . . well, maybe . . . but how about you? Is it all okay with you that the ARRL refuses to let anyone else represent amateur radio . . . and then screws up the job they've kept anyone else from taking?

What happened at Geneva in 1971? If you go back and blow the dust off your old *QST*, you'll read the story . . . our "representatives" went to the conference without preparation. They were completely surprised by what happened and had no plan to meet the situation. They found the delegates from the third world countries anti-amateur radio, largely due to not knowing much about it. This is a natural situation and one about which I've been writing for many years.

If the ARRL had spent even a tiny fraction of the membership funds which they are squandering on plush offices to get out there and meet government officials from smaller countries, we might well have the bright prospects of synchronous satellites and several thousand megahertz to experiment with.

So call me anti-ARRL if you want . . . I'm *not* anti-League or pro-League . . . I just am telling you what is what. I don't think amateur radio would do any worse if the League were to fold up tomorrow . . . as a matter of fact, it might be beneficial because then someone might set up a national club which would be run for the benefit of the amateurs instead of a small group of career "hams" in Newington. I put "hams" in quotes because I have little indication that any of them pay much more than lip service to the hobby.

If you are an ARRL member and you have no objection to a bunch of guys in Connecticut spending your money on lovely offices while pretending to serve you, then you have no gripe. If you don't mind losing 99.99684% of your satellite frequencies at a conference where *you* paid the bills to be protected . . . all okay. This is probably a small price to pay for being pro-ARRL.

If you do object to the charade of pretend representation . . . of getting along with no lobby in Washington . . . with losing your frequencies in huge gobs . . . with the damnedest rules being spawned by the ARRL and being passed by the FCC (have you really forgotten "incentive licensing" yet?) . . . if these things bother you, then, dammit, speak up and let that bunch of parasites know you want a change. The next time an election of directors comes up, make sure that someone who is more interested in amateur radio than the power and prestige of being an ARRL official is put up for election . . . and elected. Within two years you could change the League completely, since half of the directors are elected every year. Within two years you could get in a bunch of fellows who could turn the ARRL into a powerful lobby for amateur radio . . . who would make sure that nothing like that Jack Anderson column happened.

As far as saving our bacon at the 1979 WARC conference, it's too late to count on the ARRL. It would take two years to get enough directors elected to turn things around, and the conference will already be upon us. Those third world countries are still anti-amateur radio, and you can bet that when it comes to a choice between frequencies for a bunch of American hams or for their own needs . . . or even remotely possible needs . . . we are not going to get the vote.

This is purely a matter of public relations. Amateur radio is of immense importance to these countries . . . only they don't know it. No one has gone over to visit them and show them what amateur radio can do for them in the way of helping their country to develop . . . getting them technicians and engineers for their communications . . . spreading the word about their country to the people of other countries. As far as I know, this has happened in just one country . . . and I did that. It can be done . . . so why isn't the ARRL doing it?

Okay, so it is too late to get any help from the League . . . what other possibility is there? Sure, I can get out there and visit a country a year . . . which might end us up with two more votes for amateur radio. But I'm already working 100 hour weeks just trying to keep up with what I've got going now. You need some teams out there . . . and this takes money . . . and the only group with a whole lot of money is the ARRL (and they're spending it all on new plush offices). Well, what about the ham industry? Maybe they can get something hung together in time to do some good. I'll talk to them about it, but in the past the League has been able to discourage such industry groups from getting together . . . we'll see.

If the industry can get together and get something started, I think *73* will back them as much as possible. We need to get into contact with third world countries . . . we need a lobby in Washington desperately . . . one which can contact Congress (the ARRL is forbidden by law from lobbying) . . . and can keep in touch with the FCC to help them provide us with the best rules possible.

With the ARRL failing on all counts, I see no other hope than our ham industry.

COWAN PUSHES 220 MHZ CB

CQ's publisher has gone to the newspapers with a CB column distributed by King Features, the main purpose of which seems to be to force the FCC into putting CB on the 220 MHz ham band. A recent column went on to exhaustive length about the joys of using repeaters for autopatch operation . . . and then went on to say that CBers could make all these fantastic free phone calls from their cars at a fraction of the mobile telephone rates if they would force the

FCC to open up the 220 MHz band for CB. Who knows, Cowan may be right ... all it may take is pressure from a few thousand CBers on their congressmen to make the FCC take our ham band and turn it into another citizens band. Congress pulls a lot of weight.

The next time you are thinking of supporting *CQ*, you might just refresh your memory on this one. It wouldn't hurt to bring it up at the next club meeting. Cowan, who publishes the largest of the CB magazines and the smallest of the ham magazines, obviously has his chips bet where the money is ... on CB. *CQ* is small because of neglect ... Cowan tells us this in his own editorials. My understanding is that he is just making time with it until the FCC comes through with the Communicator license, at which time *CQ* will become a Communicator magazine ... in competition with *Ham Horizons*.

LOOKING ON THE BRIGHT SIDE

All these worrywarts who are griping about the ARRL make me sick. Why not look on the happy side of things? Sure, we stand to lose a good part of our low bands at the 1979 WARC meeting in Geneva, but the loss certainly isn't going to be as catastrophic as the 1971 debacle when we lost virtually all of our satellite frequencies ... under ARRL representation. In case you've forgotten, the ARRL went into the conference with 237,254.77 MHz in satellite ham frequencies and came out with 7.5 MHz, a loss of 237,247.27 MHz ... 99.99684% lost.

In most fields a group that provided that quality of representation would be replaced, but not in amateur radio ... the ARRL still has the 100% enthusiastic support of most amateurs despite its total impotence. That's real loyalty and should be applauded.

As I say, it doesn't seem possible that we can get quite the screwing on our low bands that we did on the VHF bands, though there is no one who understands the situation who is in any way optimistic. It does appear that we will lose large parts of the low bands, since even the United States appears to be ganging up against the League on this.

When we lose parts of our bands, we will merely have to economize. Any study of the usage of our bands will clearly show that we can substantially increase our efficiency of operation. Take those pileups of stations trying to make rare DX contacts ... the actual contact takes perhaps 15 seconds ... the calling and interference drags it out for hours for hundreds or even thousands of operators. All that has to be communicated is the call letters and signal strength, something which could be compressed into less than a second with a good fast RTTY system ... perhaps with the help of a computer. DXpeditions could work thousands of stations per hour and still generate virtually no QRM.

How about nets? If you listen much above 14,275 you hear hundreds of nets, many spending hours trying to finish their lengthy call-in procedures. This is another natural for modern techniques ... some fast RTTY with a microcomputer and the net of five hundred stations could be checked in ... in a few minutes.

This is getting exciting ... how about two meter repeater operating? About 17% of the air time on a repeater is used in repetitive indentifying ... a natural for new techniques. Will the 1978 two meter rig have an LED readout to show the call of the chap you are contacting? No reason why not. A quick blip will give the call and handle at the beginning of each transmission.

Perhaps we can go further with this ... since 23% of repeater time is spent by fellows calling someone else who is not there to answer, this could be automated ... and reduced to almost nothing. Calling CQ on the repeater ... yes, I know we don't call CQ, but we do call CQ, only in other words ... could be sped up, too. We're getting places now ... another 8% of the contacts are involved with a description of where the mobile operator is driving at the time ... perhaps we could agree to delete this relatively unimportant data. 11% of the air time is spent describing the gear being used ... and since this comes down to perhaps a dozen different rigs, we could encode that with one single character. Perhaps you see where I'm headed ... with over 99% of the average ham contact strictly routine, why not achieve some real efficiency by setting up an accepted group of abbreviations? This could cut QSOs down to a second or two each and permit far more hams to use what few channels we have left after 1979.

If this doesn't get your vote, then I have an alternate plan. Since the ARRL has done about the worst possible job of representing us that it was possible to do, perhaps we should look around for some other group to step in and do a better one. I think I have a suggestion along this line ... one that will surprise you. The ARRL isn't the only group out there pushing for frequencies ... there are many other groups ... such as the EIA ... but these others are not ham groups, so we might get stabbed in the back if we depended on them ... even so, it might not be worse than we've been getting. Never mind, the one group of hams that has been getting a lot of play recently are those great chaps down at *CQ Magazine*. Dick Cowan WA2LRO is making real progress in his push to get the ham 220 MHz band turned into a CB band ... he seems to be doing a lot better at it than the ARRL is in trying to stop him. And George Jacobs W3ASK appears to be working with incredible success to get choice ham bands for his beloved Voice of America ... George is the *CQ Magazine* propagation editor.

I realize that this is heretical, but how about turning to *CQ Magazine* as our representatives instead of *QST*... since *CQ* seems to be doing far better at what they are doing than *QST*? We have nothing much more to lose.

DRAFTING HELP NEEDED

We're looking for someone to move up here and work at drafting diagrams for *73*, *Kilobaud*, and our books. Most of this work is farmed out right now, which means delays. If you enjoy this sort of work and are good at it, drop me a line.

THE MICROCOMPUTERISTS

Of the somewhat over 10,000 hobby computerists who have their own computer systems up and running, about 2,500 are licensed amateurs. And, judging from the interest in computers shown at hamfests and conventions, the percentage of computerists who are also hams is going to hang right in there.

There are a growing number of hamfests which are combined with computerfests ... a combination which is the best of both worlds because most hams are interested in computers these days ... and vice versa.

Considering the number of amateurs who have been playing around with microcomputers, the number of good articles submitted to *73* has been quite low. I'm most anxious to get all of the information I can on how to interface these gadgets with our ham stations ... I'd like to see articles on I/O devices ... on uses around the ham shack ... on problems you've run into and how you solved them ... on experiments with high speed computer generated and computer decoded Morse Code ... on any experiments with ASCII ... on any of the new hardware being brought out which is particularly useful for hams ... etc.

Despite enthusiastic articles about the microcomputer industry in most of the professional computer magazines and in papers such as the *Wall Street Journal*, the fact is that this is still a very small and fragile business. Most of the firms in the field are much smaller than you might imagine and the sudden appearance of any major firm could be disastrous. There is an interesting and perhaps destructive dichotomy involved ... these small firms have a psychological need to be accepted by their larger and older brothers who make the mini and maxi computers, and so the small firms are forever trying to get promotion which will call attention to themselves in the field ... yet if they succeed in getting the attention, any one of a hundred larger firms could easily put many, if not most, of the micro firms out of business.

The manufacturers and dealers in the hobby computer industry are getting together to form an industry group, and this might give them enough strength to weather an invasion by one of the behemoths. It would be nice to keep this as a field in which a small entrepreneur could put his idea into production and do well for himself ... and that is where it is at right now.

Actually there are a great many ways to turn the computer hobby to a profit and a hobbyist has to be either remarkably lazy or not in need of funds to miss out. Some are doing quite well by keeping track of their adventures with getting their systems to work and writing for the many computer hobby magazines ... there are about nine or so which publish this sort of thing ... make that ten, counting *73*. Other hobbyists are either working for computer stores or opening them ... and they are on the whole faring well. Some are writing programs for profit ... some doing consulting work ... some inventing hardware and selling it to manufacturers ... some are getting into manufacturing.

What about all those magazines? They run the gamut, from *Personal Computing*, which is beautifully done and aimed at the pre-hobbyist, with articles telling of the things you can do with hobby computers, but low on construction projects ... to *Creative Computing*, which is a sort of fantasyland combination of school computing and science fiction ... *PCC*, People's Computing Company, a newspaper type of publication aimed at school use, particularly by youngsters ... *Kilobaud*, aimed at the newcomer to hobby computing, with articles on hardware, software, and systems. *Kilobaud* is packed full of material of interest to hobbyists. *Interface Age* is a fat magazine loaded with new product releases and a few articles aimed more at the OEM market and not too much for the hobbyist. *Byte* is going higher and higher level, aiming at the scientist and advanced computer engineer, and is a bewilderment to the newcomer.

COMPUTERMANIA

Over 12,000 computer hobbyists turned out for the recent San Francisco Computer Fair ... making about 200 exhibitors very happy. The Civic Center was so crowded that you could barely walk around ... and no wonder, for the exhibitors were showing some absolutely astounding devices and systems.

Along the ham line was the new ham board from the Digital Group ... one board with RTTY, SSTV and Morse code on it.

The next big computerfest will be at Atlanta on June 18-19 ... part of the Atlanta Hamfestival. If you are within driving distance of Atlanta don't miss this one.

In July (30-31) the action will be at Seattle, the first big computerfest in the Northwest ... not to be missed.

In August we'll be running Computermania ... the biggest exposition yet of microcomputers. This show will go all the way from advanced calculators, through video games and microcomputers, right on up into small business computer systems. This will be at the Commonwealth Pier in Boston on August 25-26-27th ... Thursday, Friday, and Saturday. The show will be run by *73* and its staff.

We're expecting over 300 exhibitors and 25,000 or more attendees. It will be the biggest and best show yet in the whole field of small computers. If you are interested in looking at what is available in microcomputers and shopping around, this will be the place to go.

Make your plans accordingly.

RTTY Loop

Most active hams have operated on the low bands, chased a bit of DX when it's around, and joined in on the fun on 2m FM. Some have even tried 220 and 432, with a hearty few tackling 1296 and EME. However, if you are like most of the amateurs I know, the day-to-day "routine" of hamming needs an occasional change of pace. Two meters can get old pretty fast when the local repeater group is stagnant, and even the dedicated rag chewer tires of fighting the QRM on 40 every evening.

If you are sick of cranking up on .52 every night, and 75 has you down, possibly a new mode will liven up the time you have allocated for hamming. Let's look at the possibilities: Let's see, there are those OSCAR satellites up there, and SSTV, and what about FAX, TV, microwaves, or RTTY? And, how about those microcomputers, which can be tied into almost every facet of ham radio? There is no excuse for anyone being bored with ham radio, and if one facet of communication is getting old, there is always something new to try. For openers, consider RTTY! Here is a mode that offers just about everything. It does not cost a fortune to get on RTTY; it will be seen that a complete RTTY station can be assembled for under $100! The required printers and keyboard are commonly available, and the electronics can be assembled from readily obtained parts. A radioteletype station can be used on most of our bands, and interfaced to existing station equipment. RTTY also lends itself to state-of-the-art techniques — many hams, myself included, have interfaced computers to existing RTTY equipment, and it shouldn't be long before "quiet" RTTY stations based upon surplus video displays are commonplace.

Interesting things can happen when a group of hams stumble on a new mode. Last summer, a friend with a RTTY station got me interested, and within a matter of days I was on 20m and 2m with a $25 keyboard-printer and inexpensive terminal unit. Well, one thing led to another, and by Christmas a highly active net had formed on a 2m splinter channel. It didn't take long for others to find out what those weird tones were, and soon never-before-heard 2m stations were calling in on RTTY, as it is possible to monitor a frequency all day with equipment that is silent except when a message is transmitted. This "autostart" operation is only one of the special features offered by RTTY. If you're interested, read on!

In response to considerable demand from our readers, *73* is going to provide a monthly RTTY column, the *RTTY Loop*, aimed at present and potential enthusiasts. The idea for a continuing RTTY series has been lurking around for some time, but it took a combination of things to get it going. Several days ago, I received a letter from Marc Leavey WA3AJR, who has written for *73* in the past, and is presently writing a RTTY series for the Baltimore Amateur Radio Club's journal, the *Modulator*. One thing led to another, and the *RTTY Loop* was formed. Marc will provide information for the ham interested in getting started on RTTY in an easy-to-understand fashion. In following months, advanced techniques will be discussed, such as autostart, selective calling, digital control, video displays, and, of course, computer-controlled RTTY. The possibilities are limitless! Your response to this new effort is solicited. Please address any comments, questions, suggestions, and criticisms to "RTTY," *73 Magazine*, Peterborough NH 03458. I will forward all material to Marc, who is responsible for the content of the column. Let's get started, and I hope you like the column!

John Molnar WA3ETD
Executive Editor

TELE-TIPS 1

This month, and for a couple following months, we will be discussing the principles of RTTY operation. As with any new field, there are a multitude of terms and definitions that must be understood before getting involved in details. Naturally, new terms will be popping up in the months to come, and they will be dealt with when they arise. Be patient — things will fall into place! Presented below is a brief glossary of common Teletype terms. Many of these are familar, and will serve to refresh the RTTY pro. It might be a good idea to save this list, and add to it as the months pass. Each month will have a glossary of new terms, so it will be possible to maintain a complete list. Let's get started, then, with some common definitions:

AFSK: Stands for Audio Frequency Shift Keying and is a means of encoding the Teletype information by changing the frequency of an audio tone.
CHAD: When you punch a hole in a piece of paper, the plug that comes out is called a chad. Paper tape, punched with many holes to serve as a memory, generates tons of these chads.
CHADLESS: Obviously, without chads. If you want to type on the tape with the holes in it, the absence of paper where the holes are makes it difficult. Chadless tape leaves the plugs attached by little lips, to permit it.
DEMOD: Short for Demodulator, this is the electronic marvel that converts the warbling tones of rf into pulsed dc that the Teletype machine can interpret.
FOX TAPE (or KEY): There is a marvelous sentence that contains all the letters of the alphabet — THE QUICK BROWN FOX JUMPS OVER THE LAZY YELLOW DOG. One frequently has a tape to send this for test purposes. Some of the new digital Teletype setups have this sentence preprogrammed at the touch of a key.
FSK: Stands for Frequency Shift Keying. Similar to AFSK, the frequency of a radio carrier is shifted to encode the TTY information.
GOVERNOR: Not the man in your state capitol. Teletype machines are run by motors, and it is important for the motor to be turning at a precise speed. Older machines, or those intended for ac/dc work, used a governor on the motor to set the speed. A special tuning fork is used to set the motor.
LOCAL LOOP: If you hook all your equipment together so that anything you type on the keyboard prints on the printer, kind of like a big electric typewriter, that's a local loop. Essential for testing.
MARK: Spelled differently than my first name, this is the state when everything is running quietly, and loop current is present. Could call it "1" if you're into logic.
MODEL 12, 14, 15, 28, 32: These are different series and styles of Teletype machines. The Model 15 is the "standard," and consists of a keyboard and page printer on a table. The Model 19 is a Model 15 with tape equipment built in. The tape equipment alone might be a Model 12 or 14. The Model 28 or 32 is more recent vintage stuff.
PAGE PRINTER: If the Teletype machine prints on a roll of paper which, when you tear it off, looks like a page, that's a page printer.
PATCH PANEL: One of those can't-do-without things. Usually a jack strip which allows anything to be connected to anything (*anything?*).
PERFORATOR: A keyboard connected to an electromagnetic device which punches tape as you type is a perforator. This cannot punch tape from an incoming signal.
POLAR RELAY: Normal, spring return relays take more energy to make than to hold. This would cause distortion in the Teletype signal, called bias, which will be covered later. A polar relay uses two magnets, one to make and one to break, to overcome this problem. A bias (no relation) supply is needed for one of those windings.
RATT: This is the MARS abbreviation for radioteletype. Don't ask me why.
REPERFORATOR: A tape punch which decodes incoming signals and punches them into tape is a reperforator. Some versions type on the tape at the same time, and are called Typing Reperfs, of course, and are chadless!
RTTY: The ham's abbreviation for radioteletype.
RY: These two letters contain all bits in the Teletype code. Don't worry about it — we will discuss it later — but it makes a fine test signal (RYRYRYRYRY).
SPACE: See also MARK. This is the state without loop strip of paper and reminds one of the stock market ticker; it's a strip printer.
SYNCH MOTOR: Since the motor for a Teletype machine has to be a precise speed, it is nice to synchronize it to the 60 Hz line frequency. Takes the place of governor motor.
TD: Stands for Transmitting-Distributor (which is quite a mouthful). Actually, this is a tape reader.
TT, TTY: More abbreviations for Teletype.
TELETYPE: The whole ball of wax we are talking about. This is a trademark, however, and should always be capitalized.
TU: Stands for Terminal Unit, and is the same thing as a Demodulator.

That has got to be enough to digest for this month! Next time we will cover just how that Teletype machine works.

LETTERS

CLOSE TO HOME

Dear Jack Anderson,

I've been a fan of yours for years, but one of your recent columns, the one on CB vs. ham radio, struck close to home. The one-sided nature of the column was unfortunate.

Radio amateurs (hams) must pass an examination, which includes knowledge of the international Morse code. By international agreement there is to be *no* hobby use of the spectrum below 144 MHz unless the operator has demonstrated this knowledge of Morse code. Technically, the recent FCC rule change to allow hobby use of CB at 27 MHz is in violation of that agreement.

I believe most CBers are potential hams frustrated by the code requirements. The FCC has proposed a code-free license for frequencies above 144 MHz, but has been unable to implement it due to the crush of CB license applications. It would seem more constructive to support the implementation of this proposal, rather than to encourage the expansion of CB chaos at the expense of hams.

Phillip Nelson WA6PNA
Albany CA

POLITICAL FOOTBALL

I truly believe amateur radio is about to face its toughest hour, which will decide if our hobby will continue as we know it or slowly "pass away." Amateur radio is definitely becoming political football in Washington DC. More and more, it seems that the sides are being drawn up between amateur radio and CB, or David and Goliath. If we are not properly prepared for this fight, we will lose our only national resource forever, i.e., the ham frequencies.

The enclosed Jack Anderson article is filled with half-truths, insinuations, misleading statements, etc., which to the average reader portray hams in a very unfavorable light. Note the quotes from Anderson's article — "The FCC is quietly stifling the millions of voices that jam the CB radio frequencies . . . The Commission has favored the few (hams) over the many (CBers) . . . 300,000 hams have 100 times more frequency allocations than are available to CB . . . ARRL is a lobbying organization" . . . and on and on. But, there is no mention of the purpose of amateur radio, its contributions to public service, national welfare, communications developments, history, service in emergencies, and so on.

I would consider this article to be extremely damaging to amateur radio. Can you imagine the impact this article will have on the US Congress? Please do whatever is required to answer this extremely biased article.

Havertown PA

CAHOOTS

Mr. Jack Anderson
c/o *Washington Post*
Washington DC

You had some rather harsh things to say about amateur radio operators in your *Washington Post* column of April 4, 1977. Most of what you said was false. Most of what you insinuated was false. You insulted every amateur radio operator in the United States.

You implied that myself and my fellow hams are in cahoots with the Federal Communications Commission and are in some way depriving the Citizens Radio Service operators of frequency spectrum space that rightfully should belong to them.

Your first mistake was to equate the Citizens Radio Service and the Amateur Radio Service. Both services use radio and there the resemblance ends.

The purpose of this letter is to provide to you some basic information regarding both radio services so that when next you write about ham radio, you will have some facts for reference. I speak for no one but myself . . . and I feel sure, thousands of ham operators. I thank you in advance for your time and attention to what I have to say.

First, examine how the respective radio service licenses are obtained. The amateur radio operator took a series of tests administered by FCC engineers that covered radio theory and practice, rules and regulations of U.S. as well as international amateur radio, and demonstrated proficiency in sending and receiving international Morse code. Failing to pass any one test results in no license.

The Citizens Band operator filled out a simple form about as complex as applying for a social security card. That's all. In fact, under today's rules, the Citizens Band operator gets a temporary license when he buys his equipment. He has that to use while he waits for the FCC office to issue his permanent license.

Look at both licenses. What really do they cover?

Amateur radio operators hold an equipment license that covers the station itself. He also holds an operator's license. The ham is personally identified. Only he can operate his radio equipment. Other people can talk over it but his hands must be on the controls at all times. There are exceptions to those rules, but they involve other licensed amateurs.

The Citizens Band operator does not hold an operator's license. Only the radio equipment is licensed — not the operator. Because there is no operator's license involved, any relative of the person named on the license can operate the station (over age 18 only). The Citizens Band operator is not personally identified.

What is the charter of the two radio services? That is, what is expected of them? Both are utilizing a public property, a resource, the electromagnetic spectrum. It is not infinite. With regard to the Amateur Radio Service, the Communications Act of 1934 put heavy emphasis on ". . . value of the amateur service to the public as a voluntary noncommercial communication service, particularly with respect to providing emergency communications." That language is still in place and is taken very seriously by hams worldwide. Many hams maintain emergency power sources for their stations so that no matter when an emergency call goes out, responses to the call can be made. Citizens Radio Service operators also provide communications for the public good and that is commendable, but the hams have been honing their communications skills since 1913. The hams have the organization, the expertise, the network of stations and, most important of all, the strict radio discipline that results in efficient operation no matter what the situation.

The list of instances of ham radio as the principal and many times the only means of communications is almost endless. Some of the most recent were the earthquake in Alaska in 1964, Peru in 1970, California in 1971, Guatemala in 1976, Italy in 1976, the Dakota floods and the Big Thompson Canyon, Colorado, Hurricane Agnes in 1972, and recently and locally, the Frederick flood in October, 1976.

The charter of the ham operator includes contribution to the advancement of the radio art and electronic advancement, self-training and technical investigation solely with a personal aim and without pecuniary interest of any kind.

The mission of the Citizens Radio Service? To provide private short distance radio communications services for business and personal activities of the licensees. There's quite a difference isn't there?

To address some of your comments in the *Washington Post:*

How can the FCC be stifling the Citizens Radio Service when it just granted 17 additional channels on Jan. 1, 1977?

Why do you say that the Amateur Radio Service should give up spectrum space to the Citizens Radio Service? We gave up the space they now occupy.

The hams don't have a lock on the higher frequencies. Quite the opposite. And those frequencies are *not* interference free.

The hams do not control any frequencies. Only the FCC can make frequency assignments and that task has got to be one of the most difficult and thankless chores in the world to do. It's a no-win situation every time.

The ARRL has put out no "flash bulletin," and it is illegal for *anyone* to transmit on an unauthorized frequency, be it ham, CBer, or ordinary businessman.

This letter is being released to the news media, governmental officials, and the American Radio Relay League.

David R. Halliburton WA3ZOR
Gaithersburg MD

"AIRSPACE"

Editor
The *Washington Post*
Washington DC

The article by Mr. Anderson strongly implies wrongdoing by the Federal Communications Commission (FCC) in its regulation of the Citizens Radio Service ("CB") for the benefit of the Amateur Radio Service ("hams"). Although basic information in Mr. Anderson's article is factually true, it is distorted and incomplete. It reveals both a lack of knowledge on the subject of radio communications and a lack of professional reporting in the art of journalism.

The major issue made in the article is that hams have more frequency spectrum ("more airspace") than the vast majority of CB users, public service user (police and fire departments), FM radio broadcasters, and TV stations in Los Angeles and New York City. This is a true statement. But Mr. Anderson apparently does not understand that radio frequencies differ in characteristics.

At very high frequencies (VHF) and ultra high frequencies (UHF), radio communications are extremely reliable and almost interference-free — necessary traits for police and fire units. But, these frequencies are extremely short ranged. Therefore, it is quite feasible for a small frequency spectrum to be used repeatedly throughout an area as large as the United States. Because of the short range characteristics of these signals, Washington Metro Police cars will not be erroneously receiving instructions from Los Angeles police dispatchers.

Citizens Radio Service (CB) has — and still is — intended to be a short range service also. The low power (4 Watts) was to limit range of these radio sets to just a few miles. But when the service was established in 1958, the FCC took frequencies away from the Amateur Radio Service in the high frequency (HF) band. This range of frequencies — and especially in the spectrum which includes CB frequencies — is especially conducive to long range radio communications. Combined with high powered amplifiers (illegal but widely used on CB frequencies) and directional antennas, radio conversations can literally be "skipped" over thousands of miles.

This is why legal CB operators like myself have so much difficulty trying to talk to someone else just a mile away.

Without illegal use of CB privileges, the service would have almost enough radio frequency spectrum for the near future. In most areas of the US (outside of metropolitan areas), little activity occurs on more than a half dozen channels. The FCC has been experimenting with establishing new CB frequencies in the 900 MHz range which would improve reliability of local communications and prevent long distance communications. Most amateurs would be in favor of this move.

The Amateur Radio Service was established to promote the art of radio communications through experimentation, the development of trained personnel, and to promote international goodwill through radio. All of these goals require access to frequencies throughout the radio spectrum.

Since radio began (Marconi claimed himself to be an amateur), hams have been at the forefront of new developments. Much of the present "state of the art" of radio and television communications is either directly or indirectly the result of amateur radio. Most of the electrical engineers and researchers in the area for the past fifty years became interested in radio as youngsters through amateur radio activities. One of the most significant breakthroughs for reliable long distance voice communications – single sideband – used by the military, civil airlines and ships, and by CBers, was entirely developed by amateur operators.

Also since the beginning of radio, hams have been quick to step in and offer communications assistance during times of disasters. The only communication with the outside world for weeks following the terrible Guatemalan earthquake was by amateur radio. The American Radio Relay League (ARRL) even contributed a VHF radio system for local communications inside Guatemala. The Guatemalan government and the Red Cross have recognized that relief efforts there would have been almost impossible without the reliable communications of hams in the US. Similar examples can be given for any number of disasters here in the US and abroad.

Since the radio frequency spectrum became "managed" in the 1920s, frequency allocations for amateurs have shrunk. Yet the number of hams in the US and worldwide has increased. Not only the CB radio industry (which stands to profit even more by more frequencies being assigned to CBers who would have to buy new radios), but many other radio services covet the frequencies now held by the Amateur Radio Service. It appears to users of those services that there is no opposition to taking frequencies away from hams. Contrary to Mr. Anderson's implication, the ARRL is prevented by law from lobbying. Many amateurs and members of the ARRL, in fact, feel the ARRL is not doing enough to protect the interests of hams. Arrayed against the unprotected hams are the airlines, the boating industry, the broadcasters, and the CB manufacturers. Mr. Anderson acknowledges this when he wrote about ". . . giving the CB *industry* a greater share of the airwaves" (emphasis added). The airwaves belong to the people, not to any industry.

Amateur radio should be viewed as a national resource and protected. Not just because it is a hobby, but because of its continuing contribution to public service and to the development of higher levels of electronics state of the art. It is open to all – even CBers like myself. The only requirement is a desire to learn a little about radio and pass a code test. And if I can do it, anyone can!

Sterling Park VA

SENSATIONALISM

Mr. Jack Anderson
c/o *The News American*
Baltimore MD

In your syndicated column of April 4th, a 1977, entitled "Hams Hog The Airwaves," your story seems bent more on sensationalism than in presenting a true picture of amateur radio (ham) or Citizens Band (CB).

You contend that the Federal Communications Commission is quietly stifling the millions of voices that jam the Citizens Band radio frequencies. You further contend that 300,000 hams have 100 times more airspace than is available to the nine million CB enthusiasts and that the hams also have a lock on the higher frequencies, which are free from interference. Let us examine, in depth, your allegations.

First, while it is true that the 300,000 hams of the United States do have more airspace or frequencies than are allocated to the Citizens Band radio enthusiasts, the basic purposes and licensing requirements of the two services are vastly different. It must be remembered that amateur radio is an international service covered under agreements of frequency allocation by the International Telecommunications Union, of which the United States is a member. The Citizens Radio Service is not international and therefore not provided for by the ITU. All that is required of an individual to be licensed in the Citizens Radio Service is merely filling out a form and mailing it to the Federal Communications Commission. On the other hand, for a person to become a licensed amateur radio operator (ham), he or she must first demonstrate to a duly authorized individual the ability to send and receive international Morse code at a speed of five words per minute, along with a written examination encompassing basic radio theory and the rules and regulations of the service. This procedure will entitle the individual to what is appropriately called the Novice or beginner's license. Lest you get the idea this examination is of great difficulty, the youngest person to date to be licensed as a Novice was, in 1976, aged five years. Most hams, however, are between age 15 and 75 and also are truck drivers, teenagers, doctors, lawyers, housewives, etc. We don't, however, lay claim to having a former First Lady within our ranks, but do have many well-known personalities: Senator Barry Goldwater and entertainer Arthur Godfrey, to name two. The licensing requirements do become more difficult, but are commensurate with the privileges bestowed. It is not the intention of the amateur community to exclude any portion of the citizens of this country from obtaining and becoming hams. To this end, the various clubs and organizations, with the help of The American Radio Relay League, conduct free classes to help anyone interested in becoming a licensed radio amateur.

From your article one might infer that sheer numbers is the only requirement for any group to have a larger frequency allocation. I shudder to think what utter chaos application of such a philosophy could have upon the airwaves in a country. You further contend that, should the Citizens Radio Service (CB) be granted more frequency spectrum, it would have to come from the ham radio operators. You fail to mention why this would be necessary, except to say 300,000 against 9,000,000.

To state that personnel of the Federal Communications Commission, because they have traditionally been hams, is like a wolf guarding the flock is irresponsible. The people at the Commission are truly dedicated civil servants.

Your statements about hams controlling more frequencies than all the nation's police and fire departments combined, plus all commercial and educational FM broadcasters, plus all the TV stations on the VHF channels in Los Angeles and New York City is again inaccurate. Had you taken the time to check, you would have found that below 30 Hz, where most of the amateur activity lies, the entire spectrum allocated to the hams encompasses approximately 3.5 MHz. Just one TV broadcasting station occupies 6 MHz of bandwidth, or almost twice the entire high frequency allocation of the entire amateur service.

To state categorically that the hams have a lock on the higher frequencies, which are allegedly free from interference, is again inaccurate. There is still allocated to the Citizens Service a portion of the UHF spectrum in the 460-470 MHz range. The free from interference statement is also incorrect, for no service can be totally free from interference without discipline, regardless of where it is in the spectrum.

It is my objective to attempt to rectify a few misconceptions that you or your staff have about ham radio and Citizens Band. I hope I have been successful. However, should you desire more information, please feel free to contact me.

IGNORANCE

Mr. Jack Anderson
c/o *The Reporter Dispatch*
White Plains NY

I would like to object to your April 4th column, "Hams Quietly Stifling CBers." It is an unreasonable, one-sided presentation which ignores half the facts. Please consider the following:

1. Far from being an exclusive club, amateur radio is a hobby open to all. To encourage newcomers, amateur radio societies and magazines have for decades published books and pamphlets on how to get started. A stepped-up recruiting campaign to entice CB operators to upgrade to amateur radio has, during the last two or three years, included several book/cassette teaching packages (including one from Heathkit, the nation's largest electronic kit manufacturer), three films, local classes, and spot advertisements on local radio and TV stations.

2. Entry into amateur radio is not difficult; five-year-old kids have done it, as well as 80-year-old retirees. The equipment costs no more than some CB equipment. Ham radio is merely a hobby radio service which legally permits many of the practices presently found illegally on CB. There is nothing to prevent those CB operators who desire more frequencies from upgrading to amateur radio. Hams will welcome them with open arms.

3. One of the major reasons why the Federal Communications Commission has not granted more frequencies to CB is that Citizens Band is presently populated to a large extent by unprincipled scoundrels who disobey every rule in the book, abetted by manufacturers and dealers who make and sell CB equipment designed to violate the law. On the other hand, amateur radio is a largely self-policing service where peer group pressure results in virtually no illegal operation. Are you proposing that the law-breaker be rewarded with more frequencies taken from the law-abiding citizen?

4. It does not take a "confidential report" to conclude that radio amateurs control more frequencies than all the commercial radio and TV stations, etc. Had you merely looked at the FCC regulations, you would have seen that amateur radio oper-

ators are assigned an *infinite* amount of frequencies — everything from 30,000,000 kilohertz and up. Traditionally, ham radio has been assigned all the frequencies above the useful range at the time. It is ham radio operators who have always in the past extended the state of the radio art by finding a use for the "useless" frequencies assigned to them. All the frequencies now used for FM broadcasting, TV, CB, shortwave broadcasting, military, police, fire, and mobile communications, were once considered useless, and equipment for using them was developed by the amateurs.

5. Please keep in mind the differences between CB and amateur radio. Originally intended for point-to-point communications for the small business and personal user, CB has degenerated into a vast party line used primarily for yakking. Psychological studies have investigated the effect of unidentified operation — anonymity guaranteed by the use of "handles" — on the psyche of users; interesting trends have been observed. On the other hand, amateur radio is an orderly service which combines operating privileges with technical expertise. In exchange for taking a technical test, ham operators are permitted — even encouraged — to design and build their own equipment and experiment with its use. Many of the pioneers in electronics and radio got their start through ham radio. In time of war or emergency, ham radio operators have formed a pool of trained operators and technicians. Their contributions have been so widely recognized that almost every country in the world has an amateur radio service.

6. Finally, one might ask whether the cries for more frequencies for CB are really justified. By many estimates, over 50% of radio transmissions are *voluntarily* confined to channel 19. Can't the other 39 channels suffice for the other 50%? Perhaps the way to make more room for legitimate CB use is to crack down on illegal and improper operation, rather than to simply allow it to spread over a greater area. When CB is widely used for evading police radar, perhaps it is time to reduce rather than expand CB bandwidth. Moreover, expanding into inherently short range amateur bands which cannot in any way be policed unless the FCC sets up a nationwide grid of monitoring stations every few miles is only an invitation to further improper use.

Please, next time you write on this topic, consult a ham radio operator for the other side of the story. It will do much for your credibility on unknown issues if you present a fair and unbiased story in those cases where a sizable number of readers are familiar with the facts.

Mt. Kisco NY

GOT YOUR EARS ON?

Mr. Jack Anderson
c/o United Feature Syndicate, Inc.

I am sure you will never receive this letter, since I am sure your loyal minions would not allow you to receive mail critical of your column. However, I am so incensed over the above-entitled article ("Hams Hog Airways" — Ed.) that I am willing to use my valuable time in order to attempt to contact you. Therefore, with the unlikely circumstance that you are personally reading this, I would submit the following:

Although I cannot dispute your numbers, which you have quoted, you certainly have failed to understand any of the underlying implications. I hope that your other work does not reflect the same lack of understanding that this article exhibits.

For your information, all frequency allocations for the radio spectrum are set by the International Telecommunications Union, whose offices are in Switzerland. The frequencies which are allocated to hams have been approved by this Union, which is composed of every nation in the world. The frequencies which the CB enthusiasts "enjoy" are actually allocated to amateurs on a worldwide basis. The United States has, in fact, violated this international agreement by providing for the Citizens Band radio service. The original purpose for the Citizens Band has been distorted to the point that it is not recognizable as the Federal Communications Commission originally envisioned it to be. Therefore, the Citizens Band mess should not even exist. It appears that the only reason that there is a problem results from the inability of the Federal Communications Commission to enforce its own rules regarding the Citizens Band. If you don't think there is a Citizens Band problem, listen to the obscene language, the threats of abuse, inane conversations, etc., which permeates these frequencies. Also, check with the Federal Communications Commission with regard to the amount of complaints regarding radio frequency interference to home entertainment devices and see what percentage of them relate to Citizens Band operation. At the same time, check with them regarding their proposed rule making which will now ban the manufacture of linear amplifiers even for amateur radio use because the Citizens Banders have been using them, illegally, on their own frequencies. At the same time, you might ask the Federal Communications Commission how many hams they have had to put in jail and how many articles of equipment have been seized as being illegal from amateur radio operators and at the same time obtain the same figures for Citizens Banders. In the same light, also ask the FCC about the term "sliders." You will find that this refers to the illegal practice by CBers of operating on frequencies that have not been allocated to Citizens Banders. These fine people whom you appear to believe should enjoy the good graces of the FCC operate on frequencies assigned to other radio services. Amateur privileges near the Citizens Band start at 28 megahertz. The Citizens Band lies somewhere in the region of 27 megahertz. One megahertz, for your information, is the equivalent distance from the low end to the high end of the commercial broadcast spectrum. Therefore, you can see that there are quite a few "frequencies" available which do not have to be taken from the hams and given to the CBers. However, the CBers have not waited for the FCC to give them these frequencies, since they now proliferate in the region above the authorized CB channels and the 28 megahertz frequencies belonging to the hams. Not only that, these fine citizens are known to occasionally stray onto amateur radio frequencies.

Another item of small import which you have failed to recognize is the theft associated with Citizens Band equipment. In fact, Citizens Banders have so little technical ability that they even steal ham equipment, unusable on their own frequencies, in ignorance, thinking that they are stealing another Citizens Bander's equipment. Of large importance to me is the fact that one of your fine and abused Citizens Banders removed my antenna designed for 144 megahertz from my vehicle just yesterday for his own use. Since it will not operate with his Citizens Band equipment, I hope he has many fine hours trying to find out what is the matter with that "stupid" antenna.

Although CBers get quite a bit of recognition for their "public service" work, that appears to be the only area of justification which they can claim. In addition to allowing citizens to evade police radar, etc., these fine citizens do occasionally notify the proper authorities with regard to stranded vehicles. Hopefully when someone with a CB set reports that they are stranded, the law enforcement authorities appear first instead of their other fellow CBers who come to rape and rob because their victims have identified their location and their inability to escape.

From a historical standpoint, hams have "earned" their frequencies. Although now, because of the sophistication of communication devices and the expenses involved, hams are not as apt to be at the forefront of scientific discovery, a brief examination of the contribution of hams working in their basements on their own time would be illuminating to you, I am sure. From the time of Marconi to the present, many of the pioneers in electronics have been hams. Briefly, Lee DeForest, the inventor of the triode tube, was a ham. Also, the first radio telescope was invented by a radio amateur. It is my understanding that all significant advancements of the state of the art up until the invention of the transistor by the Bell Telephone labs have been made by hams. Hams have pioneered new techniques in television transmissions, bounced radio signals off the moon and have assembled, launched and used their own communication satellites. Hams are also pioneering, today, the field of facsimile transmission, VHF repeater work, and computer-related technology. Hams, because of the licensing structure, must be technically proficient and dedicated. CBers simply have to have ears and a mouth. Quite often the two are not connected. Therefore, as you can see, from a technical standpoint, 300,000 hams have made a significant contribution to the advancement of radio science while your 9,000,000 licensed CBers have since simply caused a pain in the neck to the Federal Communications Commission. Additionally, for your edification, Citizens Banders are not "licensed." Amateurs are. CB operators simply have a permit, which if you bother to check, is quite a significant difference.

In addition to the technical advancements attributable to hams, this pales in comparison to the public service work provided by hams. You have been perhaps too busy to read the newspaper accounts of the communications services provided by hams to Nicaragua, Guatemala, Alaska, and other areas hit by natural disasters. The news services were aware of the fact in the recent Nicaraguan and Guatemalan disasters that for up to two weeks, ham radio operators were the only reliable communications link with these two countries, and the hams were able to coordinate with rescue operations to an extent unmatchable by any other radio service. Don't take my word for it. Check it out. At the same time, you might also contact the disaster agencies responsible for the relief operations in Colorado following the Thompson Canyon flood of last summer and the Teton Dam disaster in Idaho. You will find that hams were at the forefront working many, many volunteer hours to assist in disaster relief operations.

In addition, check with knowledgeable sources as to what the "eye bank net" is all about. You will find that this is an organization of hams who volunteer their own time to coordinate between the agencies responsible for locating donors and recipients for corneal transplants and making sure that the critical time necessary for the removal of the cornea and delivery to the recipient is minimized. In addition, hams maintain contact with the National Weather Service to provide storm warnings for impending hurricanes, aid police departments and provide communications during power outages, and provide many, many other forms of public assistance at times of national disaster. You might also learn, if you take the time to find out, that hams have also spent many hours running "phone patches" from our service personnel in Antarctica, Southeast Asia, and other military installations around the world to their relatives in the United States. All of the above is done without any chance of monetary return, since that is forbidden by FCC regulations.

Additionally, amateur radio operators constituted a vast pool of trained operators for the military during World War II.

By FCC edict, amateur radio exists to promote the communications art, the technical phases of radio, and to provide public service. Please show me, if you can, where CBers are under any compulsion to do anything beneficial to anyone other than them-

selves.

You seem to imply that the FCC has some special love for ham radio. It should, because hams provide so much more service to the public than CBers ever thought of doing. If you do bother to check out the Thompson Canyon flood of Colorado, ask the authorities how the amateur radio operators and the Citizens Banders compared in their ability to effectively assist them in their relief efforts. The news articles we saw in the West indicated that the Citizens Banders were "prima donnas" who got in the way and the amateur radio operators were highly skilled, dedicated, and conscientious in their efforts to assist the authorities.

You apparently suffer from a malaise known to radio aficionados as alligatoritis. You are all mouth and no ears. If you had bothered to do any checking at all regarding the background of the ham-CB question, I am sure you would not have written your article. I would also like to comment that you appear to have been "duped" as you are wont to accuse the federal bureaus assigned to monitor big business. You have been listening to the garbage spouted by the Citizens Band manufacturers and supported by the EIA, all of whom have been pushing to "get *more* frequencies" so they can sell more CB sets. Shame on you.

Although I have been a ham radio operator for 18 years, I must admit I have not "done my share" to justify my license. However, there is a local woman who was able to talk to her brother and family doctor in Sao Paulo, Brazil, when her mother was dying of cancer, to be kept informed of her mother's condition through the use of my radio. I am sure if you asked her whether or not amateur radio was "worth it," she would answer an emphatic yes. After many times trying to reach her family by telephone in Sao Paulo and sending many telegrams, she was quite surprised that in less than half an hour on my radio, I was able to connect her with her mother's doctor in a hospital in Sao Paulo. On several other occasions, I managed to have her talk to the rest of her family and have them visit about her mother. Upon being informed that the many hours which I spent in her behalf were "free," she was amazed.

On *amateur radio* frequencies, the above are daily occurrences. The really extraordinary cases are those involving amateur radio operators in remote parts of the world obtaining rare medicines in the United States and having them shipped to the foreign country in time to save a person's life who is in critical condition.

In 1979, the World Administrative Radio Conference will occur. At that time the entire radio spectrum will be reallocated. The black eye which the United States has suffered by allowing the CB mess to develop will hurt amateur radio operators. If that occurs, thoughtless articles like yours will surely attribute to ham radio's loss and ultimately the people of the world's loss. If you are as concerned about humanity as you claim, you will revert your position and use your considerable influence in Washington to encourage the preservation of the amateur radio frequencies.

From reading your column and that of your predecessor, Drew Pearson, I know that you are "never wrong," so I do not expect to see anything in your column reflecting your erroneous thinking. That would be a shame, since you have so many people believing you speak the gospel.

In closing, I would simply like to say, "Hey, ratchet jaw, have you got your ears on?"

Stephen Guelde W7INH
Wheatland WY

RIDDLED

Chicago Daily News
Chicago IL

The April 4, 1977, article on the Federal Communications Commission and amateur radio by Jack Anderson was so riddled with mistakes and half-truths that I have outlined them in red in the enclosed article. Anderson has done irreparable harm to the good name of the amateur radio operator, *a reputation that has* been earned through over a half century of unselfish service and experimentation.

Anderson insinuates that the FCC is working against the CBers' cause by some secret intent. Nothing could be further from the truth. Since 1971, the Commission has been attempting to help the Citizens Band expand and grow. But the estimated 20 million CBers, half of whom haven't even bothered to get an FCC license, have consistently ignored every attempt at "cleaning up their bands," so that orderly growth can be established. Unleashing these undisciplined, unlicensed radio operators on other portions of the radio spectrum is inviting more television interference, more use of unlawful radio, and an enforcement burden that the Commission cannot possibly handle.

Another Anderson comment: "These (frequencies) would have to be taken from the Ham Radio Operators." This is absolutely false. Megahertz of unused government allocations lie in various portions of the radio spectrum; space set aside for UHF television is almost totally unused.

Anderson: "The Hams also have a lock on the higher frequencies, which are free from interference." I think Mr. Anderson would find it hard to defend his opinion of a "lock" on frequencies by the amateur service, for hams have only 4 megahertz of exclusive use in the entire usable VHF and UHF spectrum, which is 900 megahertz wide. An estimated 150,000 amateurs use this band daily. 79.2% of all usable amateur bands are "shared, on a non-interfering basis" with other services, notably, the government. This sharing arrangement can exist only if both parties are disciplined, state-of-the-art communicators. Sharing was originally tried on the Citizens Band, and it resulted in the "ma and pa" stores and offices, those that could profit most by inexpensive two-way radio, being forced off CB by the personal, illegal hobby user. Would you want to share a band with these people?

And, again, Anderson insinuates that these radio band allocations were all done secretly. Ridiculous! Frequencies are assigned at international conferences after years of negotiations and public dockets. CB interests are represented at these conferences, just as amateur radio is.

None of the FCC commissioners is an amateur, though some of the staff are, but they certainly are not being secretive about it. Most of the FCC hams are CBers, too. And what difference does that make, anyway? If anything, a ham license should be a point in their favor. The amateur radio operator must pass an FCC license exam on radio theory, electronics, and rules and regulations. The fact that some of the FCC staff are hams just proves that these individuals are active in their field of interest. No other radio service allows experimentation and research. Should these individuals be castigated for their interest? Who would you rather have as an FCC radio engineer, a ham or a CBer?

Anderson states: "The opposition to giving the CB industry a greater share of the airwaves has been largely generated by the American Radio Relay League . . . a lobbying organization." Absolutely wrong. The ARRL is not, and never has been, a lobbying organization in Washington. And, in fact, the ARRL has come out repeatedly in favor of orderly CB growth, for many CBers find, after becoming frustrated with the limited range and utility of CB, that they wish to pursue an amateur radio license. Amateur radio wishes CB well, but not at our expense, not at the nation's expense. Amateur radio has turned many citizens on to the world of electronics, has taught them a useful skill, and benefitted the world with more communications breakthroughs than any research facility in the country. And all this has been at little expense to the taxpayer.

Amateur radio is growing by leaps and bounds, and America will benefit from the communications and research skills that are being developed. What new techniques have CBers engineered?

The ARRL indeed has asked its members (through a "flash bulletin"? — be serious!) to prevent the "incursion of CB buffs into their airspace."

The FCC, it so happens, is also quite interested, because thousands of CBers are operating totally outside of their assigned bands, in outright defiance of federal law and international treaty. Amateurs have pledged that CBers will not illegally utilize amateur frequencies, and are working, on their own time, with federal authorities to help track down and prosecute these violators.

Raymond Spence, the FCC's chief engineer, though an amateur, has also made decisions we feel are detrimental to amateur radio too, but we don't hold it against him. He's also a CBer, by the way.

Amateur radio has been the backbone of communications research in this country throughout the twentieth century. This research continues today. Day to day public service is performed by the over one million hams around the world. In emergency situations, hams have often provided the only link with the outside world, via their self-trained and dedicated force of radio operators.

Amateurs are all for CB, but to reassign already crowded amateur bands to "everyman" CB radio, to use as he sees fit, would deal a death blow to the amateur community and in effect reward the CB community for its lawlessness. What a nice way to say "thanks" to what FCC Chief Wiley, who (incidentally) is not a ham, has called "the most disciplined of all radio services."

Mr. Anderson has made a mockery of the term "investigative journalism" and has defaced the good name of the amateur radio service. I only hope that our federal representatives in Washington are informed enough to know that his article is full of half-truths and downright lies, and give it the attention it deserves.

THE UNSAID TRUTH

The *Washington Post*
Washington DC

It is unfortunate that Jack Anderson's column concerning amateur radio is so ill-researched. What is true but unsaid is that the great public service of amateur radio on both a local and worldwide scale takes frequency space, personal and innovative

technology, and selfless dedication. This is in contrast to an untrained, unprepared, and ill-disciplined CB operation which cares not for self-improvement or solutions to its interference and public relations problems. Virtually all of the quarter million amateurs are both able and willing to provide competent, public-spirited, technically clean, and valuable first class service to the public. How many CBers can say as much individually or collectively?

The CB crowd is very vocal about their public service, but what can they really do? By example: On Friday, April 1, I witnessed an automotive accident, radiotelephoned the Alexandria police through the Tyson's Corner WR4ABR autopatch repeater, and had help on the way before an observing CBer could even find somebody willing to pass along the message.

Some research on Anderson's part would have shown a large proposed CB allocation in the FCC's WARC proposal at 900 MHz, a location which does not conflict with valid amateur operations. Perhaps he should do his homework before he writes.

CB is both a valid and valuable means of personal communication, but its services, capability, and reason for existence should not be confused with amateur radio. It is a shame that the *Washington Post* has not informed the public of what amateur radio gave during the Frederick flood, the bicentennial celebration, the recent Cherry Blossom Festival, the Nicaragua earthquake, and the daily accidents on the beltway. Amateur radio is needed both locally and internationally, and before this is forgotten, it may be time for amateur radio to make its voice as loud as its service is strong.

Theodore W. Edwards Jr. W1AJS
Alexandria VA

THE HINT

The *Washington Post*
Washington DC

I would like to comment on the editorial by Jack Anderson and Les Whitten concerning amateur radio that appeared on April 4, 1977. Mr. Anderson clearly distorted several facts and overlooked others in his comments concerning "airspace" allocations for amateur and CB operators. It was claimed that amateurs hold "100 times" the space occupied by the Citizens Band, and that the FCC was refusing to "take the hint" concerning the CBers' requirements for additional frequencies.

Mr. Anderson failed to indicate that the FCC is currently studying the feasibility of additional CB frequencies in the 900 megahertz region — those "interference-free" frequencies referred to in the editorial. Unfortunately, no frequencies remain interference-free when utilized by masses of operators. Mr. Anderson should listen in on the 40 meter ham band some evening, an area rendered almost unusable by foreign high power broadcast stations.

It should be noted that an impassioned plea for additional frequencies by any service, CB included, can only result in the bedlam that exists now on the present CB frequencies. Before opening a new band, a large amount of research into the effects on other users must be conducted. There have been several proposals for new Citizens Band frequencies; unfortunately, most would have resulted in interference to television and other services. There is nothing "confidential" about these proposals and other FCC actions. A simple call to the FCC by Mr. Anderson would have been enlightening.

The FCC does not regulate frequencies arbitrarily. Most amateur frequencies have been assigned by international treaty, and it is impossible for "traditionally ham" commissioners to allocate band space to new services without conforming to international law. A recent proposal for additional CB frequencies was rejected by the Canadian and Mexican government, as interference would have been caused to their services. Unfortunately, radio waves do not adhere to national boundaries.

The FCC *has* taken the hint, and is attempting to find new frequencies for CB use. It is not the CB operator who is harassing the FCC commissioners; it is the manufacturers of CB gear looking for additional profits that will result when new bands are opened. No mention of the operator was made in the editorial. It is this person who will bear the expense of new equipment and antenna systems when new bands are allowed for CB use.

In conclusion, it is important to note that Mr. Spence of the FCC, the American Radio Relay League (ARRL), and the 300,000 hams were powerless to prevent the loss of 99% of their bands when a recent international conference eliminated most of the "interference-free" satellite bands once available to amateur operators.

Executive Editor
73 Magazine

ONE SIDE

Enclosed is a column from the *Miami Herald* of April 4th, and, just in case you do not get this Jack Anderson syndicated column, I wanted to forward it to you.

I feel that some knowledgeable individual, such as Wayne Green, should write to Mr. Anderson outlining all the benefits and good that ham radio operators have done for the last fifty years. It would seem that he is getting just one side of the coin from this article.

Personally, I think that the CBers should be given one of the UHF frequencies — and let them have their fun. Maybe that will keep some of them from operating illegally in the ham bands or from becoming two meter technicians and carrying over their poor operating techniques into this operation.

Nevertheless, Mr. Anderson should be rebutted because of the distortion and obvious impact this could have on the general public.

Frank Nankin K4BNZ
President, Palmetto Amateur Radio Club
N. Miami Beach FL

BAD PR

I'm sending along a xerox copy of an article published in the *Rockford Morning Star*, April 4, 1977, written by Jack Anderson, the noted (??) columnist. It shows how much a guy can twist facts and how much he knows about ham radio.

I'm asking *every* ham to let this guy know what ham radio is, the public service that's been done, and how twisted his "confidential report" is.

His address is c/o United Feature Syndicate, 200 Park Ave., New York NY 10017. Give this guy a piece of your mind because this is bad PR for ham radio, especially with WARC coming up.

Tom Carney WB9RXJ
Sterling IL

CROSS POLLINATION

Just a quick note to thank you for the "Briefs" column by WA1GUD and WA1UMV. We have long needed a forum for "cross-pollination" of ideas from various clubs throughout the country. This can only result in a more informed, healthy, and active ham radio fraternity. "Briefs" fulfills a need, and I, for one, thank you for it.

Rich Casey WA9LRI
Arlington Heights IL

TOP BAND

I'd like to see an article on the pros and cons of 160 meters, along with some details relative to the construction of antennas for this band.

L. Lyle Baker K5QJT
Mineola TX

Glad you mentioned that. This issue has a feature article on the King of 160, Stew Perry W1BB. A new 73 book, The Challenge Of 160, *is hitting the presses in a few days. Stay tuned for some great 160 articles in coming issues. — Ed.*

TRIGGERED

Yes, we did receive a refund from Trigger Electronics, the same outfit that we all seem to know about. It wasn't easy. Our problems with them were almost the same as those described by Mr. David B. Hasenick of Springport MI.

We wrote many letters, both to Trigger and then to the Illinois Attorney General's Office. Trigger responded by sending us small lightweight items in large boxes. The airmail postage was almost double the cost of the item. Then after several more letters to the Attorney General's Office with copies to Trigger, we finally received our refund of the balance.

Several months later I received a letter from the Attorney General's Office advising me that the State of Illinois was going to prosecute. The details of the letter were made available to Wayne Green. I had hoped that he would place it in the "Letters" section so all could note the contents and then write to the Attorney General Office and perhaps receive a refund in the coming court action.

Lajas, Puerto Rico

PR THROUGH PS

During the recent East Greenbush-Castleton (NY) area March of Dimes Walkathon, members of WB2YCR, the Amateur Radio Club of Maple Hill High School, were involved with the communications along the walk route and even operated a portable station on battery power.

Actual communications along the route were provided by the Rensselaer County RACES/AREC Association, of which I (the club's sponsor) am a member. I set up communications at one of the checkpoints along the walk route and allowed students to listen to the RACES communications as a means of demonstrating the use of amateur radio in public service, for which the RACES organization is famous.

At the same time, another portable radio station was set up under my direction by student radio operator Geoff Schad WB2EQN. This station operated solely from a 12 volt battery provided by media staffer Stuart Hague. The antenna used was a twenty meter dipole set up on portable supports. Using this simple rig, Geoff was able to talk with several stations, including two in Florida (W1BDF/4 and W4QC), WBØSMK in Lincoln, Nebraska, WBØCHH in Springfield, Missouri, and K4APL in Perry, Georgia, all during the Walkathon.

The Walkathon provided two golden opportunities. One, to provide a public service through RACES, and secondly, to test our club station's portability. It also provided valuable portable operating experience for Geoff and our student operators.

Castleton NY

HELP ABROAD

I just received my March *73* today and noticed in the "Ham Help" section a couple of more articles from individuals requiring help while overseas.

One article asked, "How can I get a license overseas?" The FCC has been coming to Europe (Ramstein AB, Germany, and Mildenhall RAF, England) every six months for the past year. They were here March 21, 22, and 23, and should be back again in September. Most MARS stations and education offices will have the exact information in July or early August as to the dates of arrival.

I have also been asked a number of times, "What kind of American activity is there in Germany?" Answer — "Everything." In Germany all US forces and dependents can obtain a German license very easily. All that is needed is an address (operating location), a valid stateside license, Technician or above, and 39 DM ($16) a year.

Activity within Germany is in almost all modes of operation. As a General or above you will be given a German Class B License. With this license you can operate up to a maximum of 150 Watts plate dissipation on any of the following frequencies — 160m by special permission, 3.5-3.8 MHz, 7.0-7.1 MHz, 14.0-14.35 MHz, 21.0-21.45 MHz, 28.0-29.7 MHz, 144-146 MHz, 430-440 MHz, 1250-1300 MHz and more above. All the above frequencies may be used in the following modes — A1, A2, A3, A3J, F1, F3.

These modes are for the entire band. There are no class or subband allocations. There is a great deal of repeater operation on 2m and 70 cm. Universally within Germany, 145.500 MHz is a mobile calling frequency and 145.525 and 145.550 are simplex.

There are a number of American amateur radio clubs within Germany. I could go into each of them, but a visit to your area MARS station will render you information about clubs in your area. I am a member of the Wiesbaden Amateur Radio Club, so, being biased (hi), I will say a little about it. We meet the second Tuesday of every month at 7:30 pm, and of course everyone is invited. Most club members can be found on 145.550 MHz FM.

Any interested person can write to The Wiesbaden AB, MARS Station, APO NY 09457, or myself, and we will try to answer questions and offer assistance to individuals about amateur radio within Germany.

There are also radio theory and code classes being held on Rhein Main AB and Wiesbaden AB, continually. I would imagine with the amount of American activity, there are many other classes being held. Again, visit your local MARS Station.

CT7001 FIX

I greatly enjoyed Mr. Kufchak's article on "The Super Clock" — using the "old" CT7001. I used the same chip in my clock which has been running fine since 1973. Well, actually, there is one minor problem or I wouldn't be writing this!

Every so often, while in the 12 hour mode, the pm bit in the time or alarm register (or even both) gets set. (So, instead of waking up at 7:00 am for work, one sleeps through until dinner time!) I'm pretty sure the problem is in the chip (and, therefore, extremely difficult to correct), but I'd like to know if others who have used this chip have a similar problem, or if this is an isolated case. Any feedback would be appreciated.

Oh, as a suggestion for battery backup, use the "display enable" line to blank the display to conserve energy, and use a blinking LED or something similar to indicate loss of 60 Hz.

Roy Weidig
513 Lamplight Ct.
Middletown OH 45042

THE REAL ONE

When I picked up my first copy of *73* (OSCAR issue, July '75) in Hong Kong, I realized that it had to be the only real "amateur" magazine on the market. The others merely label themselves as such. I don't believe any other magazine has the coverage *73* does. During a recent overseas deployment, I saw book peddlers in Karachi, Pakistan, Subic Bay (Philippines), Singapore, and Hong Kong selling *73* — and they were the current months' editions! Never saw any other ham publications anywhere except in U.S. possessions. In my opinion, *73* has improved steadily since I first bought one. I noted the greatest improvement when the magazine went to the large format in '76.

Most of the time I'm in agreement with your opinions and definitely agree with and appreciate your openness to other opinions.

Keep the I/O section going (I realize you have no intention of ending it). It's great, as is *Kilobaud*. Both serve their functions well.

Thomas C. Johnson WB6NQK
FPO San Francisco

THE SEARS DEBATE

WA4MZL's letter about "Sears and 2M" on page 17 of the March, 1977, issue prompted you to comment, "We're on the case!" Factors to consider in the "case" should also include one or more of the following:

1. The Sears Spring/Summer 1977 catalog, page 967, actually tends to encourage CBers to move up into the ranks of amateur radio with its heading — "Ready to go beyond CB? Enter a new world of communications . . ." The "Important Note" puts the uninitiated on notice that there is a requirement that the user must be duly licensed and further refers potential users to the FCC for further details. How's that for educating the public? Could be better, you might say? Why not help Sears with their later catalog copy?
2. The ownership of equipment is an incentive. A friend recently purchased a 2m walkie and has so far twice failed his exam. He at least has the monetary incentive to push on. Incidentally, he purchased the rig from one of *73*'s advertisers without proof of a license required, and if *73* is not a catalog, mail-order sales operation, I miss my guess.
3. As indicated in "Briefs" in the same issue of *73*, the photography industry benefitted from new markets through mass availability of the products. I agree that "A vastly larger distribution network for amateur products could possibly create enough demand to give amateur radio thousands of new devotees." How about PRing many of them onto 220 and 70 cm?

As you may have gathered, I am interested in encouraging the CB members of our radio family to join our ranks — legally! To that end I wrote this letter.

Skid Schermerhorn
W1TTY/W1IOY
Wellesley Hills MA

P.S. The Sears by Yaesu looks to be functionally the same as my (purchased by mail from an ad in *73*) Wilson WE224 by Yaesu with which I am very pleased. Maybe the Sears should be reviewed in "New Products." Who knows? If Sears sells only a few of these radios, they might have a drastic price reduction and create a great bargain for many of us.

SWIFTSURE

I have been a reader of your "Letters" column for many years, and needless to say I enjoy it very much. Its contents have prompted me to write.

In the Victoria area (southern tip of Vancouver Island), the Royal Victoria Yacht Club holds the Swiftsure Sailing Classic race. As a PR venture, the Amateur Radio Clubs of Victoria and Port Angeles (Washington State) are combining efforts for the second time to handle emergency communications.

The Swiftsure Race is known worldwide and affords an excellent opportunity for publicity. We have close to 100 hams involved in 4 land-located positions, and we also equip 5 power vessels with units for patrol purposes. Communication is via the Victoria Repeater (25/85), with HF used for long haul and backup.

There are usually at least 350 sailboats involved, from both the US and Canada. Their route is west out of Victoria through the Straits of Juan de Fuca to the open waters of Swiftsure Bank, and then back the 80 miles to Victoria. To give an idea of the conditions at sea, the wind at Swiftsure Bank was 45 mph last year, with a 22 foot sea (we have an operator who doesn't get sick). The turn boat is at anchor for at least 24 hours. In closer to Victoria the water conditions change by the hour, sometimes with no wind, other times with wind and rain.

The amateur radio enthusiasm is unbelievable. To give you an idea, last year this year's planning began the day after last year's race!

This year's Swiftsure Race is May 28 and 29, and we hope it will be a success.

A.L. Muir VE7BEU
Victoria BC

SOCIALISTIC CB?

Many CBers advocate that they be given privileges normally associated with amateurs. Maybe I'm old-fashioned, but I was taught that people were expected to earn the things in this life that they wanted to receive — whether it's a pay check, more frequencies, or more power.

I don't believe I'm disillusioned. We amateurs at least partially earned our licenses by diligent study and practice to obtain our licenses. Many times I have heard the expression that no one respects anything given to them. I observe that this is also true in regards to CBers as well as welfare recipients. Neither respect what was given to them and only cry for more.

The CBers who use ham frequencies and run high power, disregarding the law, are the same as someone who is denied welfare and steals because he feels it is owed to him.

Unfortunately, this reflects an attitude sweeping our nation. Until it is changed, our society will continue on a path of socialistic decline.

Harold White WA4CPF
Birmingham AL

CRAZY

I wanted to say that I enjoy reading your magazine. I'm not too crazy about all the computer articles, but I wasn't too crazy about 2 meter FM a few years ago when you were pushing that idea. Now I have two 2 meter FM rigs.

I'm also very glad that you're around to keep people on their toes! Many times, when I read your comments or answers to some of the letters you get, I find they reflect my exact feelings! I definitely do not feel, as I'm sure many others do not feel, your last name reflects your character (e.g., the letter "The Golden Helmet," Jan. '77). I think you hit the nail right on the head more often than many would like to admit!

Also — a special thanks to Don

Jenkins WA6OAZ for the fine article on getting 88 channels with 2 switches on the Icom IC-22S. A fantastic article, as many of the articles in *73* usually are!

Finally, as far as good experience with manufacturers goes, I must put in a good word for Amateur Electronic Supply. I've been dealing with them for about 4 years now, and haven't had anything to complain about. Ray Brenier K9KHW is always very pleasant on the phone and very helpful. Their used equipment has always arrived in mint condition. Great service on new stuff, too.

Dave Buda WA2RYC
Nutley NJ

TVI IS CURABLE!

I am interested in knowing any hams interested in reactivating 6 meter AM (in the metropolitan NY-NJ area). I am 16 and have finally acquired my Technician license (I didn't think I would ever reach the ranks). So c'mon fellas and/or YLs (TVI is curable). Drop me a letter and let me know. There have to be some 6m AM rigs around and I only own an AM rig, so it's only fair for myself. So let's hear it!

Kenn Ramirez WB2KQO
675 Knickerbocker Ave.
Brooklyn NY 11221

Watch out, or Ch. 2 will get you! — Ed.

10M CB

In regard to the proposed 10 meter frequencies published in the "Letters" section, how about moving it up 5 kHz so the converted channel 14 would be 28.715 and now be on the 10-10 net frequency? Perhaps this would encourage 10 meter operators to convert a radio to use from home or in the car on the net. Help promote 10 meter activity!

Douglas Reed
St Paul MN

FREE CLASSES

The Flushing (NY) Radio Amateur Technical Society is sponsoring *free* licensing classes in the Flushing area. For more information, drop us a postcard: FRATS, 62-26 Boelsen Crescent, Rego Park NY 11374.

Stu Weinstein WA2BXJ
Rego Park NY

LLOYD AND IRIS

We have just completed operation as W6QL/VP2A. We made 10,000 QSOs with hams in 126 countries. This is an all-time record for our various stops. The large number of QSOs was due, in part, to participation in the first weekend phone and the first weekend CW portions of the ARRL International DX Competition. We made nearly 4,000 QSOs (before eliminating duplicates) in the 48 hours of operating in the phone contest. This is the largest number of QSOs we have ever made in 48 hours. We remember world-famous contest operator Jim Neiger W6BHY telling us that in one contest he made 4 contacts a minute for an hour. At the time we did not see how it could be done, but we did almost the same thing in the contest just concluded.

Lloyd (W6KG) and Iris (W6QL) Colvin at VP2A.

Band conditions have been excellent. For example, we worked all continents in 30 minutes on 14 MHz SSB on 21 February 1977. Stations worked were UF6VAG, VK4AK, YV4YC, IK7RNH, XE1DPF and ZS6DN.

Lloyd Colvin W6KG
Iris Colvin W6QL
Antigua, W.I.

DVM FEEDBACK

I've been following Wayne's career, through the mags he publishes, for quite a few years. I must say that I enjoy *73* very much, especially the article on VR6TC and the mention of KV4AA. In 1956 I used to be VP2LB, so I know what it is like to be DX. Now I am settled in Canada and just about ready to be a VE3 after many hectic years in this country.

The main reason for writing this letter is to clarify some errors on page 60 (Fig. 1) of the Feb 77 issue ("DVM's Get Simpler"). Seems that Gary McClellan, in trying to straighten out the errors in that schematic (in the April '77 issue, p. 17), has introduced more errors. C3, the .01 uF, should move to pin 10, not 9; also the 10k resistor R3 should be between pin 10 of IC2 and pin 7 of IC3. Also, C2, the 47 uF capacitor, shows the wrong polarity. Positive should be on pin 7 of IC2.

Boris Auguste
Hamilton, Ontario

HORRIFIED

I recently received the April, 1977, issue of *73 Magazine* and was horrified to read "Those Illegal CB Channels" by John Skubick K8ANG. I am appalled that your magazine would condone such illegal activity.

My value system is such that I cannot support any publication which condones and even suggests illegal activities.

Therefore, cancel the remainder of my subscription to *73 Magazine*. I shall expect to receive a prompt refund for the cancelled portion of my subscription.

David A. Deem WA3ZXI
Rosemont PA

Please reread my article again, word-for-word. It is fact-filled objective reporting, written in a somewhat sarcastic vain. We hams, as a group, have always conducted ourselves within the law. (I, for over 22 years.) Yet we are constantly being harassed (such as by incentive licensing), and now possibly by restrictive designs placed upon our low band equipment, due to CB related activities.

Yet, the 11 meter band has been expanded to further accommodate some of what was once illegal. More channels have been added, and the rules are relaxed.

Speaking of that word "illegal," it is used throughout my article, including the title. This is the only word I know of that means "unlawful," "forbidden," and "not condoned." Don't you agree? — K8ANG.

LOOKING WEST

While your "Looking West" column is one of my favorites, I take great exception to WA6ITF's comment that there "was not a repeater to be had" while traveling through our Central Coast area. We do have excellent repeaters with lots of activity. Perhaps the machines are a little bit on the quiet side on a Sunday evening, but the times are rare that you can't put out a call and make a contact. Perhaps he should have tried "kerchunking." "Kerchunk" is the sound of a falling squelch tail brought on by a quick flick of the mike button. Of course, one should identify when doing this. Kerchunking 16/76 in San Luis Obispo would have brought to life WR6ADS, Cal Poly's local machine.

Also in SLO you will find the Central Coast's oldest and widest coverage machine, WR6AEL on 22/82. A little twist of the dial, another kerchunk, and up will come our newest repeater — WR6ASW. Located in Santa Maria, this machine covers from San Luis Obispo to the top of the San Marcos pass near Santa Barbara. As designer, owner, and trustee of this machine, I fought hard to get a good site and the best frequency pair, none other than the granddaddy of them all, 34/94. 34/94 was chosen to make the machine useable to a maximum number of persons, transients included.

Traveling south from SLO, one soon comes to beautiful Shell Beach, and while its excellent restaurants are enough to make most of us forget radio for a little while, an insistent kerchunker will discover Lompoc's own WR6AVI on 72/12 — an excellent repeater with coverage almost to the Gaviota tunnel.

In summary, one with only common channels in his radio will have 3 or 4 repeaters to pick from in this area, while those with full coverage can pick up Nipomo's WR6AHZ on 81/21 or WR6AFI on 60/00 with coverage from SLO to Thousand Oaks. All of our machines are carrier access, on the air 24 hours daily, and fully open to all licensed amateurs. We have open autopatch on three of the machines with exchanges covering Los Osos, Baywood Park, SLO, the Five Cities, Nipomo, Santa Maria, Los Alamos, Vandenberg, and Lompoc.

Regarding operation on other bands, WR6AEL has an open 450 repeater as well as a 450 system that controls a 52.525 radio. By the time Mr. Pasternak makes another trip through this area, WR6AHZ's 220 MHz system will be operational, and two open 450 systems in Santa Maria will be operational, one from the WR6ASW site, although our 450 frequencies will be per the national band plan, not the upside down Southern CA plan. Other things being planned but not presently operational include adding a 6 meter receiver at the WR6AHZ site with a 450 link to WR6AEL's 6 meter transmitter to complete a 6 meter, split site repeater on the most popular 6 meter channel per the national band plan.

While we do have good equipment on the air here, we also have good users. We do not need tight controls. Our autopatches are fully open and the codes are published. A high percentage of the local hams even have the repeater control codes. Most of us are not the "new breed." Many of us were rag chewing on 75 and working DX on 20 before we ever heard of a repeater. Several of us are members of QCWA and several of us are in high

school or college. Q signals we understand, but few of us know the difference in a 10-7 or a 10-8, and we are not interested in learning. We have no jamming, no attempts at long distance calls on our autopatches, and we jump to answer a distress call.

The point of this letter is that the Central Coast is not an rf desert. We welcome and encourage transient traffic on our fine repeaters. If you can't work our repeaters, we will even help you build a decent antenna.

Robert C. Couger
Santa Maria CA

THE POWER DEBATE

My comments may not sit too well with some equipment manufacturers and the "big boys," but perhaps the forthcoming ban on commercial linears is a blessing in disguise. Why does anyone need more than a couple of hundred Watts anyway? The only reason that I have found in over twenty years of hamming is to punch through the other signals, with the result that you are probably being heard not only by the person(s) you are in contact with, but by most of the country as well, and causing unnecessary QRM to boot. If the power limit was, say, 200 Watts pep on the high frequency bands, think of the reduction of QRM. Sure, there would still be the same amount of signals, but the level of QRM would be so greatly reduced that working around it would usually be a breeze. The great power myth is easily disproved by listening on the bands in the wee hours when most U.S. hams are grabbing some ZZZZs and hear the DX stations running one or two hundred Watts roll in. So the idea being put forth by some that all the new rigs would have to be expensive high-powered ones is possibly just a manufacturer's dream.

There would be some spinoff benefits from such a power limitation, such as a reduction in energy use and shifting the frustrations of not being able to compete with the super power from the average ham to the ex-super power ham who in most cases can better afford psychiatric care.

I doubt if such a power reduction will ever take place, but if it should, I wouldn't shed a single tear as I dismantle my trusty linear.

Harl Goodwell K6JQD
Paradise CA

You touched a sensitive point, Harl! I have always been dismayed by the use of excessive power on our bands. Possibly it is because I am not a seasoned DXer — sometime I will get into serious DX and my philosophy might change. However, while in college, I worked WAS minus two with 50 Watts CW, and it didn't take forever. With the abundance of good antenna designs around, it is a shame that more hams don't take the time to erect "superior" systems (apartment dwellers aside!). The same theory applies to VHF and UHF. Recently I have been involved in 432-450 MHz experimenting, and it's amazing what can be done with low power (under 50 Watts) and a good antenna/preamp/transmission line setup! The current crop of 2m transceivers all have fantastic receivers — a fact that reduces the amount of power required for dependable communications. I often wonder what it would be like if there was a universal 250 W power limit on HF communications. It might be interesting! High power is required in certain applications, such as EME, but should be employed only when necessary to maintain communications on HF, and I don't mean when blasting through a pileup on 20. I would like to hear from others on this subject — I'm open to criticism and will gladly open the letter forum to comments. — Ed.

20M QRM

The other day on 20 meters I had been monitoring the Intercontinental Traffic Network, in hopes of being of help to someone somewhere. A W5IH(?) station operating mobile in New Orleans began calling CQ on the frequency. There must have been at least 100 stations listening on that frequency. He was asked to move off and got very indignant about that. He continued to operate and QRM the net.

He said that he was sick and tired of all these nets on 20 and would not QSY, as he did not give a damn. I wonder what he thought we actually are about. I would like to publicly explain to him what we do and accomplish for us and him — yes, him!

First of all, one of the main reasons we hams are licensed and are allowed to be on the air is that we are here to promote international goodwill. When we run phone patches and other types of traffic, we certainly serve to further international goodwill, not only between other hams but to non-ham individuals as well. How much international goodwill did he render to his country by calling CQ and working a W8 station and exchanging signal reports, while people in maybe 20 countries were QRMed? We don't wish to take any fun away from anyone, whether he runs DX, SSTV, CW, mobile, etc. But please, try to cooperate with us, who enjoy running traffic. We have to share the band also. Remember that without a netting frequency to congregate onto, there would be hundreds more transmissions going on by people looking for connections somewhere — resulting in even more QRM on 20 meters.

By running traffic we are fulfilling one of our requirements for receiving our tickets. Please work with us, not against us. Use your energy to improve our bands. Maybe you could start a drive to clean up splatter, or perhaps work together to open more frequencies. There would be less QRM and more enjoyment, as we pursue our pet preferences in this wonderful hobby.

Chet Brown WB2AHK
Woodhaven NY

HOME BREW

As a home brew fanatic, I am constantly involved in those guerrilla wars we have all reluctantly come to accept as a way of life when venturing into the marketplace. It's been more years than I'd like to remember that I've been searching for dependable vendors, and any day now I should be receiving my battlefield commission.

I write up many projects and have had my share of pages in the ham magazines. The point is that a single article can sometimes result in literally hundreds of inquiries from interested readers who, for the most part, want to know where they may obtain parts for a project. I very rarely answer with a specific name, as I've learned from experience that I'd be making more enemies than friends.

Whenever I try a new supplier, I send him a small order just to see how it turns out. If all goes well, I keep this place in mind for the next time I need his kind of merchandise. If my order receives shabby treatment, however, I scratch the name from my list.

The candid "Letters," reporting personal experiences that other readers have sent to this column, are quite helpful and a sorely needed service for the harassed consumer. However, the results are not always consistent. After reading a favorable report on Quest Electronics, I sent my usual "test" order for $8.90. After waiting a month, I wrote a letter canceling the order and requesting a refund. I was not even extended the courtesy of a reply. I wrote again 3 weeks later and subsequently received a partial refund. This meant another letter, inquiring after the remainder of the money I had sent for parts they didn't even have, and which were still being advertised months later. (Too bad we can't claim expenses and compensation for all the aggravation.)

Perhaps we should start a "preferred vendors list." Anyway, I've put in my two cents worth, and with inflation it is worth even less, but I do feel a little better for having done so.

Raymond Megirian K4DHC
Deerfield Beach FL

THE RFI BILL

Senator Adlai Stevenson
United States Senate
Washington DC

Since moving to Illinois I've never written to you, but a bill recently introduced in the Senate is of vital interest to me, and should be to all Americans.

I am writing in vigorous support of S-864, Sen. Barry Goldwater's RFI (Radio Frequency Interference) bill.

I speak from experience, as both an active amateur radio operator for over 15 years, and as a TV and stereo buff for even longer. As a ham, my equipment has always been "clean." Yet, I've faced all sorts of harassment from my neighbors because of interference to their TVs, radios, and stereos.

Repressive local laws against any amateur or CB operation are beginning to appear. It's not our fault, in the main. It is the fault of shoddily built equipment for home entertainment, which all my neighbors own.

Look at it this way — one of the major intents of the present administration is for human rights, as expressed in our Declaration of Independence and designed into our Constitution: "The right to Life, Liberty, and the pursuit of Happiness." If that pursuit of happiness is not at the expense of someone else's pursuit of happiness. In other words, I have the right as long as my signal is clean, to pursue my happiness by operating my amateur radio station, as does my neighbor to watch "Mary Hartman" or the Super Bowl. We really should never know of each other's existence. But (1) when my operating signal destroys his picture or sound, even though I'm operating a properly designed and adjusted transmitter, and (2) when various signals from my neighbors' TV sets interfere with my reception, which they do, then (3) something is wrong.

My neighbor himself is not at fault. But he paid $450-$900 for his home entertainment set, and he expects and thinks that that set should be designed and constructed much better than it is.

And so it should be. It must be, because the home entertainment equipment industry's quest for life, liberty, and the pursuit of happiness, via higher profits, is infringing on my rights and the rights of my neighbor, the consumer, to each do as we wish, because of their cheap design and shoddy construction techniques. It just isn't fair, pure and simple.

I believe that S-864 is a major step, a good start in the right direction to the day when all radio operators and TV/stereo lovers can live in peace in the same neighborhood.

The home entertainment equipment industry is not about to agree with any of this. Through their lobbying group, the Electronics Industry of America, they are expected to greatly oppose this bill. They will claim that the cost of properly designing and shielding their devices against RFI would be prohibitively costly. They said the same thing about the all-channel set law in 1964.

It proved to be a fallacious argument then, and still is, particularly in

Briefs

Compiled by Warren Elly WA1GUD

Got a good ham radio news story? Drop us a line, or call it in, and take home the 73 publication of your choice, provided we publish your news tip. Be sure to specify which book you want. OK?

At deadline: AMSAT reported a successful 2m CW contact between KP4AST and YV58UK . . . over 500 miles between Caracas and Ponce. A fourth 432 MHz EME WAC is also reported by K3PGP, who completed the all continents award with ZE5JJ. May 2nd at ARRL headquarters, AMSAT officials were planning their first A-O-D operations meeting since both groups signed an agreement turning control of OSCAR 8 over to the League. Topics to be discussed reportedly included allocation of the new satellite's passband, with many OSCAR users advocating a CW-SSB division similar to OSCAR 7 mode A. FCC license totals for CB (February) were nearly 700,000. Some Russians may be signing U60 in commemoration of the 60th anniversary of the October, 1917, revolution. The Fresno International DX Meeting drew the biggest crowd ever – over 350 DXers from far and wide. And, congratulations are in order to the beloved *West Coast DX Bulletin* (the source for the last three items). At Fresno, the *Bulletin* received two awards, one from the Southern California DX Club and another from the Golden Empire Amateur Radio Society. At last report FCC lawyers were still sorting out that cable TV case mentioned in one of this month's guest editorials. One FCC spokesman on the matter of what will happen at the Dayton FCC Forum: "We will be pretty close mouthed until more explicit instructions come from higher up . . . we will discourage discussion on pending proposals, and make a written record of the Dayton Forum for the public files on various dockets."

Jack Anderson's national newspaper column strongly criticized the FCC and left amateur radio with a PR problem under a "Radio Hams Are Favored Over the CBers" headline in early April. Unfortunately it was not an April Fool's joke – Anderson, citing quotes from Georgia Congressman Elliott Levitas, accused the FCC of discriminating against the 9 million CBers in frequency assignments, in favor of only 300,000 amateurs. Anderson's case rested on his claim that important decisions by the FCC have been made by officials who are also amateurs, and therefore biased against CBers. One FCC official termed the report "a frivolous allegation" not worthy of comment. Congressman Levitas, though, is pushing for a House investigation of the FCC. (See Guest Editorial this issue.)

Bob Hope has generously recorded some public service announcements pointing out to the public that amateur radio is valuable to the nation, inviting those interested to "join in." These will be distributed to radio stations, adding to those already being heard which were made by Dick Van Dyke. Thanks to WBNAZ.

Another record month for amateur applications arriving in Gettysburg . . . 22,927 received during March, topping the January record of 21,553. However, the backlog is growing, instead of falling. At the beginning of March the number of licenses awaiting processing was about 38,000. By the end of the month, the backlog was up to 42,000. The waiting period, meanwhile, had grown beyond 10 weeks in some cases, with the average wait somewhere near 8½ weeks.

The ARRL has filed in opposition to RM-2830, that proposal to permit rebroadcasting of amateur transmissions for traffic and emergency purposes over commercial stations. ("Briefs," May '77, *73*). In its response, the League argues that road, traffic, or weather information could not be of benefit to a commercial audience without a two-way system for clarification of the information being filtered into the studio. That, of course, would take a licensed amateur station at the broadcast studio, a requirement broadcasters would be hard-pressed to meet due to commercial considerations. The League also points out that amateur transmissions would be used in heavily commercial time periods, so-called drive times, when broadcasters not only have their largest audience, but also their highest advertising rates. Backing the WBEN plan was the National Association of Broadcasters (NAB). The League response noted that the NAB was not familiar with amateur operations, and sought to exceed reasonable limits for questionable benefit, in backing RM-2830. Buffalo area amateurs, meanwhile, were upset by the League opposition. Said one local (heard on 75m), "This isn't the time to split hairs when ham radio so badly needs better access to the public for PR . . ." As pointed out, however, in the League petition, unusual circumstances (such as disasters and so on) do allow rebroadcast of amateur transmissions, with the permission of the district FCC engineer-in-charge.

It will probably be some months (as of this writing) before the total scale of amateur operations in spring floods and tornadoes will be known. Virginia, West Virginia, and Kentucky were hard hit by floods and mudslides. Local communications went down quickly, especially in WV, where amateurs set up a communications center at the state capital, operating on a 24 hour a day basis. It took as much as 48 hours in some areas before National Guard units could arrive, and amateurs were reportedly working closely with local police using HTs and those repeaters that could be coaxed back onto the air. At Williamson WV, residents were warned of the flood by the local fire whistle, the only form of communication left as the waters crested. In another WV town the mayor was carrying a pistol to discourage looting, he told NBC News, since it would be days before help arrived. In Alabama, tornadoes tore through Jefferson County, three years to the day after the last killer storm there. Amateurs in Birmingham operated W4CUE continuously, handling traffic from the disaster areas.

There were some new developments on the FCC's proposal to ban the manufacture of linear amplifiers covering 24-36 MHz and type accept amateur radio equipment (dockets 21116 and 21117). At issue is the need for point of sale constraints on the sale of equipment to non-licensed persons (a concept the FCC had rejected). ARMA, the newly formed manufacturer's association, reacting to a counterproposal from the San Antonio Repeater Association (see "FCC," this issue), argued that the Texas plan would probably violate federal restraint of trade regulations. ARMA's proposal differs from the San Antonio plan in one key area – it puts the onus on the manufacturers, not the dealers.

The ARMA plan would require all manufacturers and importers of rf generating devices to affix permanent serial numbers and provide affidavits. The affidavits would be presented to the buyer by the dealer, who'd have to see a valid amateur license (or photocopy) prior to closing the deal. The seller would witness the signing of the affidavit, which would include the type of gear, serial number, call letters of the buyer, his name, and a statement of intent covering the subsequent use of the gear. A willful violation of the agreement would carry a $1000 fine on the buyer, dealer, or manufacturer if the FCC found any party in violation. A copy of the agreement would go to the FCC, dealer, manufacturer, and buyer, and, just like a station license, the affidavit would have to be presented upon inspection by FCC personnel. As an ARMA spokesman put it, "this plan offers fewer loopholes than the FCC's type acceptance plan, and would meet the constraint of trade regulations of the Federal Trade Commission.

One importer, in a letter to its dealers, argues against type acceptance as harmful to amateur radio. "Experience with type acceptance in other services is illuminating. A typical amateur transceiver in the 250 W (PEP) class today lists for between $575 and $900, depending on options and manufacturer. A comparable marine transceiver, type accepted, lists between $2000 and $5000, and lacks many of the technical advances found in current amateur transceiver." It

may be assumed then, that type acceptance of manufactured amateur equipment will increase its cost to the consumer, and that innovative changes will be much slower in being produced, just as in other services." The dealer's letter goes on to conclude that "since type acceptance is now desirable only as a solution to a Citizens Band misuse problem, it is beyond our understanding as to how the Commission can expect to keep high powered, illegally converted transceivers from such use, by inspecting them for purity of emissions."

A 90 day delay was announced in early April, extending the comments deadline for both dockets until August, thus opening the door to more amateur comment.

As this issue went to press, ARMA, the Amateur Radio Manufacturer's Association, was delivering an 11th hour appeal to the FCC . . . hoping to soften the first rule and order growing out of Docket 20777 (bandwidth). Effective April 15th, new harmonic and spurious emissions limits were to take effect for amateur transmitters. The 40 dB limit below 30 MHz/60 dB above 30 MHz standards replace the "according to good engineering practices" wording of the amateur regulations. They have widespread implications for amateurs and manufacturers alike.

The FCC's intention, according to a spokesman in the Chief Engineer's office, is to find a new way to crack down on illegal CB amplifiers. But, as the spokesman put it, "the net catches a bit more than we bargained for, "including several popular ham transceivers. (That's based on published specifications, not any actual testing at the FCC lab.)

The regulation covers marketing and advertising of equipment as well, and, as our source put it, "if the gear is advertised you can assume it will meet the specifications." Specifics were hard to come by at deadline, but one thing is sure — amateur stations, upon inspection, will be checked at the antenna output, thus including antenna tuners, low pass filters, and so on. It is the whole operation the Commission will be concerned about, not the individual pieces of gear. A quality low pass filter then, should put most stations in compliance at HF.

The manufacturer's reaction was about as you'd expect. One importer suggested he would no longer be able to advertise or sell gear to dealers; another warned that he'd probably go bankrupt, if forced to take back gear that wouldn't comply from dealers who couldn't sell it. ARMA President Dennis Had of Dentron Radio visited Washington with a message from the manufacturers — "We applaud the proposal because at long last we will have a concrete definition of what good engineering practices means . . . but we feel the FCC has committed a grave oversight in not grandfathering some of the equipment affected by this regulation."

Had told *73* ARMA was asking for a grandfather clause on transmitters and transceivers (not linear amplifiers) built by legitimate manufacturers, who'd be forced into bankruptcy if forced to take back dealer's inventories. ARMA also asked for grandfather clauses covering used gear that would be deemed non-salable by the new regulation. Had argued that the grandfather compromise would lessen the injustices brought by pseudohams operating illegally with amateur equipment, and strengthen the bond between amateurs, the FCC, and the manufacturers. A decision was expected prior to the April 15th effective date.

A Federal Court judge has ruled that 5 dirty words should not have been banned from the airwaves by FCC regulations. And, no, as Morton Dean reported on CBS News, "We are not going to" (list them here).

As expected, *QST*'s ad rates will jump over 40% with the July edition of the League publication. That puts one full page of advertising in *QST* at $1300 (one time), instead of the old rate of $912.

Contesting may never be the same again! In early April, at a meeting attended by 80 contestors, Murphey's Marauders and the North East Contest Club merged by majority vote, thus ending a dynasty that lasted decades. The new club, named the Yankee Clipper Contest Club, unifies the northeast, and is expected to challenge west coast and mid-Atlantic clubs for national leadership through aggregate scores in Field Day Sweepstakes, ARRL DX, and CQ WW.

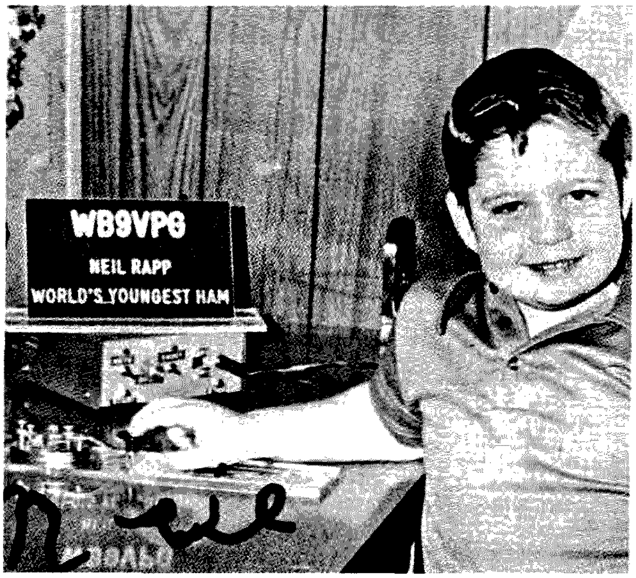
Here's an update on our "Briefs" report last month on the stolen repeater in Minneapolis/St. Paul MN. The 16/76 repeater there was vandalized and QRTed March 2nd, with several hard-to-replace items stolen. A temporary repeater was on the air within 24 hours, with a new installation scheduled to go on the air April 10th. Meanwhile, the club's rental agent has agreed to provide a safer location for the machine, including a security officer. Donations made the new installation possible, according to *The FM Scanner*, monthly bulletin of the Twin City FM Club, Brooklyn Center MN.

Neil "Rusty" Rapp WB9VPG, the world's youngest licensed amateur, has probably passed his Technican exam by now. According to Rusty's mom, the General CW may be a bit too quick for him to write down, so the General will have to wait. Mrs. Rapp herself has probably passed her Novice by now, while Rusty's dad is, by now, a General. As for the theory, six-year-old Rusty is plugging along, according to Mrs. Rapp, who says she doesn't see how he can pass . . . but she says she didn't think he'd pass the Novice either. Rusty has been getting plenty of CW practice with his new birthday present — a TS-520 transceiver from Kenwood.

As the WARC is coming up in 1979 to discuss frequency allocations, it is worth reading the report on the 1937 Frequency Allocation Conference in Cairo, Egypt. "The amateur interests were represented by the IRAU delegates, led by the ARRL's Mr. Warner. The three month long conference was not too good for the European amateurs. The reason was that most delegates of the European countries did not sympathize with the amateur movement. There were delegates who were expressly hostile to the amateur cause. Mr. Warner included the names of these delegates in his report. There have been some delegates who supported amateur aims, first of all, the USA delegation. The result was that all amateur bands were left intact for the Americas, while the Europeans lost large parts of the 80 meter band, and most of the 7 MHz band to be occupied by broadcast stations. The 5 meter band was completely taken away" (*Shortwave Review*, June/July, 1938, Budapest, Hungary). With thanks to W1PL.

A good WARC dialog between Japanese and Australian amateurs was reported at the JARL (Japan Amateur Radio League) 50th anniversary celebration last year. At a commemorative dinner party held in Tokyo Michael Owen VK3KI, an immediate past president of the Australian Wireless Institute, urged the Japanese to look ahead to the next 50 years of amateur radio. "In 1979 in Geneva, the representatives of all the countries of the world will meet and review the bands allocated to each service. There are two very important things that we should remember. The first is that each country has only one vote. Japan

has one vote. Australia has one vote. But so also has Tonga and Nauru." (Both are small Pacific Island countries of 78,000 and 5,000 populations, respectively — Ed.) "The second thing that we should remember is that there are over 300,000 amateurs in your country. The next largest amateur population in our region is in Australia, where there are only 6,000 licensed amateurs. Perhaps we should also remember that our region, which has 37 votes at the conference in 1979, extends from Iran to Tonga — half the globe." Owen went on to assess the future: "Our future is not secure. The amateurs of the world are not the only people seeking to preserve and indeed expand their bands. We must justify our position. We face particular difficulties in our region — we must remember that there are some countries where there are few amateurs and other countries where, perhaps for security reasons, amateur radio is not permitted. Indeed, in some countries it is treated with the greatest suspicion." Further on in his address Owen proposes a way amateurs in the Japanese/Australian corridor can argue amateur radio's case for the future. "The amateur service is global; the needs of amateurs cannot be judged by any country looking only at the narrow confines of



Neil "Rusty" Rapp WB9VPG, current record holder as the youngest licensed amateur, and working hard on his General at age 6.

that country. The unique contribution of the amateur service to international goodwill, training, and education is at the heart of its contribution to both the national and international interest ... The amateurs of the world must speak with one voice." Reprinted from *Amateur Radio*, Journal of the Wireless Institute of Australia.

On March 1st, the FCC extended permission for amateur ATV transmissions (fast scan) in the 420-540 MHz band. This was to allow for further experimentation unless changed by bandwidth docket 20777. Bruce Brown, operator of WR4AAG, the Washington DC ATV machine, gets much of the credit for the FCC action, which grew directly from his comments in response to 20777. Thanks to the *RF Carrier*, bulletin of the Dayton (OH) Amateur Radio Association.

ATV is on the air in California, according to *ATV Magazine*. The site is just north of San Francisco at Auburn, with coverage from San Francisco to Sacramento. The frequencies are 437.25 MHz in and 427.25 MHz out. Meanwhile, in Los Angeles the locals are reportedly building a 434 MHz in, 1240 MHz out ATV machine. Back east, Ed Piller W2KPQ, the Long Island Mobile Amateur Radio Club (LIMARC) ATV chairman, reports he's still working out the bugs on the club's ATV machine. Operating frequencies on LI are 439.25 MHz in, and 427.25 out.

The extra effort separates the "serious" from the "enthusiastic." Here, the Dallas Amateur Radio Club effort illustrates the easy way to clamp a tribander onto a crankup tower. Thanks to the DARC.

The Personal Communications Foundation, a legal aid clearinghouse set up to advise attorneys representing amateurs in tower cases and RFI/TVI disputes, has received some substantial contributions. Yaesu and Wilson both donated $10,000 to go with $5000 from the ARRL, as reported here previously. PCF is still seeking legal briefs from lawyers involved in communications cases. PCF's address is 915 W. Lancaster Blvd., Lancaster CA 93534.

AMSAT has arranged Bank Americard and Master Charge for contributions and membership dues. Be ready with the information embossed on your charge cards when calling AMSAT at 202-488-8649.

In other AMSAT news, the battery situation on OSCAR 6 was status quo as of deadline. Three cells are apparently dead (of the 18 aboard), and telecommand stations have been instructed to turn the satellite off after each orbit for recharging purposes. Both current satellites will be coming out of 100% sunlight now, forcing some changes in operating schedules. Work on A-O-D continues in Washington, now with the help of two ARRL staffers dispatched to AMSAT headquarters through the League's agreement reported in our last two issues.

AMSAT sources say that A-O-D is progressing on a tight schedule, with the launch date now on a call-up basis. At the earliest, that puts the launch at the end of the year, or early next year. Lloyd's of London is underwriting the launch (a stipulation of the AMSAT-ARRL agreement) for $50,000, in case the launch fails or a suitable orbit is not obtained. A similar arrangement was set up for OSCAR 7, according to AMSAT.

Finally, AMSAT headquarters says there are still some 1st day covers available from the OSCAR 7 launch. They go for $1 each or six for $5, by writing (or calling) AMSAT in Washington at PO Box 27, 20044.

An interesting note from England, via *Radio Communication*, Journal of the Radio Society of Great Britain, February 1977:

The severe interference emanating from the Soviet Union continues to cause problems to many services from time to time. It is reported that some European administrations have received the following message from Moscow: "Radio installations operated in HF bands are being experimented with in the Soviet Union and these experiments could possibly cause interference of short duration to your radio facilities. We are now taking actions in order to decrease eventual interference. Your reports will be attentively studied by Ministry of Posts and Telecommunications of the USSR. Regards. Minsviaz."

On a number of occasions, items of news from *Radio Communication* have appeared in the Soviet publication *Radio*. They have included extracts of information on RSGB affairs which have been distorted to place an unfavourable light on western society, and it is hoped that criticism by that same society of the present illegal activity by the Soviet Union on international frequency allocations will also receive due publicity in the same place.

How do you handle the many unsavory and questionable conversations and activities occurring on the amateur bands; The FCC says *ignore it*! Don't try to contact the people to reason or quarrel with them. Don't try to jam them. If they break into a net, and won't move, wait them out. But — do a lot of listening. Get specific information on calls, dates and times. Write down exactly what you hear. *Don't* send tapes to the FCC or make phone calls. Write down all the pertinent information and then mail it. The staff has limited time for these problems, but they are willing to pursue a good hot lead if it is well documented with enough background information. Reprinted from *The Printed Circuit*, Great Lakes Repeater Association, Detroit MI.

Another Federal Court decision, prompted by broadcasters, will affect ham radio. A US Court of Appeals panel, in throwing out some of the FCC's cable TV rules, severely criticized the Commission's rule making practices. As a result, FCC attorneys are warning Commission spokesman in decision making positions not to accept informal (verbal) comment on pending rule making proposals. It could affect "bull sessions" at hamfests and conventions, but the full impact was unclear at deadline. An earlier case brought by broadcasters resulted in the suspension of all license fees, and a Mexican standoff of sorts, as the Congress blames the Commission, and the Commission blames the Congress for the fees dispute.

As we were putting this edition of "Briefs" to bed, the word in club bulletins from one end of the country to the other was Field Day. It looks like another record-breaking year for participation, if the bulletins are portraying an accurate picture. One point to remember is that the ARRL has made the CW rule a permanent fixture of Field Day ... that is, CW contacts count twice a phone contact, so get those keyers and bugs ready!

According to the *West Coast DX Bulletin*, the Southeast DX Club (Atlanta) ran a poll of their membership on the needed ones. The following is the head of the list, notable for the listing of most of the usual "desperately needed" ones.

1. Iraq
2. China-BY
3. Clipperton
4. Khmer-Cambodia
5. Bouvet
6. Heard
7. Saudi/Iraq Neutral
8. Burma
9. D6-Comoroes
10. South Sandwich
11. Albania
12. Spratly
13. Okino Torishima
14. Kamaran
15. Bhutan
16. Laccadives
17. Bangladesh
18. Cocos-Keeling
19. Annobon
20. Geyser
21. Andamans
22. Qatar
23. Central African-TL
24. Chad
25. ZS2-Prince Ed and Marion
26. Auckland/Campbell
27. Malpelo
28. Aldabra
29. Willis
30. Mellis

Clubs across the country continue their search for new ways to relate ham radio to their communities. The Central Michigan ARC has an interesting PR-Public Service approach — a remote base setup for emergency weather alerts aimed at the general public. According to the CMARC bulletin (*The Scope*), police, fire departments, schools, and hospitals monitor

the 147.10 MHz warning frequency 24 hours a day. Hundreds of homes are linked to the system as well, since local supply shops are stocking scanner crystals. The remote base is controlled through the club repeater system, with a link to the Lansing Weather Bureau. The 147.10 MHz warning frequency is repeated through the Lansing system on a priority basis — any station on either repeater is overridden by the warning broadcasts. As John Hackman WB8QPE put it in a recent *Scope* article, "Emergencies come up quickly and without two weeks advance notice . . . ops who get the word off the air are those who help, not those who have to be reached by telephone . . ."

Two members of the North Shore Repeater Association (MA), operating on 28/88, March 4, at 11:35 pm, joined in a successful effort to prevent a tragedy, when Ed WA1LRL/M came upon a disabled car on the Cabot St., Beverly, railroad crossing, with an approaching train coming down the track.

Dick W1FAW phoned the Boston & Maine tower in an attempt to have the train stopped, but it had advanced too far down the track.

On being notified of this fact, WA1LRL grabbed several red flares he had with him and placed them on the track, stopping the train in time.

Then he and the train conductor pushed the car off the crossing, and in doing so discovered two youths who were quite ill lying across the tracks. They were assisted to safety. Reprinted from *QRA News*, bulletin of the Quannapowitt Radio Association, Lynnfield MA.

Contrary to some recent rumors and quite possibly to the hopes of those few who would like to see amateur radio's reputation for self-discipline destroyed, the second 1977 meeting of the Ohio Area Repeater Council was neither a flying circus nor a dogfight. The Council met at the Delaware County Historical Society in Delaware, Ohio, on Saturday, April 2, with representatives of 44 of its 82 supporting member repeaters in attendance (plus 16 guests).

The committee assigned to examine the use of the lower portion of the two meter band by Ohio amateurs reported that most of those SSB operators whose licenses permit operation below 145 MHz use frequencies below 144.5, and the Technician Class licensees now operating just above 145 MHz would move down if given an opportunity. Having already voiced its opposition to unrestricted repeater operation in all parts of the amateur bands, the Council voted to support the Iowa proposal to establish a new repeater band between 144.5 and 145.5 MHz and to authorize Technicians' use of 144 MHz.

Conflicting claims to priority on the 146.34/94 repeater pair in northwestern Ohio and southeastern Michigan by WR8ACT in Toledo, Ohio, and WR8AJV in Belleville, Michigan, were reviewed. The Toledo repeater was originally established in 1969; the Belleville repeater was sanctioned by the Michigan Area Repeater Council at a time when it appeared that Toledo had relinquished the frequency pair. After examining available records and hearing statements by both parties, the Council members concluded that Toledo had a legitimate claim to the frequency, and reaffirmed its earlier coordination of WR8ACT without a dissenting vote.

A strong plea was made to all present to write their senators and congressmen, urging them to support S-864, Senator Goldwater's bill that would require manufacturers of household electronic equipment to install adequate RFI protection. Thanks to W8GRG.

The Illinois Repeater Council took action at the February meeting on the issue of 15 kHz repeaters — and whether they should be "right side up" or "upside down." Illinois voted to adopt the so-called "California plan" which follows the "reverse" principle. This is the same plan followed by western Pennsylvania, Ohio and Indiana (and Michigan is reported to be studying such plan). Reprinted from the Lake Erie ARA *Repeater Newsletter*, Lakewood OH.

Malaysia has apparently acquired its first 2m repeater. Via *Amateur Radio*, the official journal of the Wireless Institute of Australia, comes the news that a frequency coordination committee has approved 147.90 MHz output and 147.30 MHz input for the system. It's to be located at Ulu Kali, with maximum power of 50 W. *Amateur Radio* also reports that Malaysian amateurs are now authorized to use RTTY.

With A-O-D in the offing, AMSAT is anxious to help club groups interested in demonstrating the satellites. A-O-D, which will become OSCAR 8 after launch (and is to be controlled by the ARRL), will be set aside primarily for educational purposes, due to its low orbit and short acquisition time. Contact AMSAT for more details.

The winner of the 1976 Amateur Radio Biting Bug Award is Anthony R. Curtis K3RXK of State College PA. The award, given to the writer of the best amateur radio article published in a US non-ham publication, is a $50 prize and plaque.

Mr. Curtis' article in the February, 1976, issue of *Popular Mechanics* was judged the best of over 50 submitted in the competition. Entitled "New Satellites Make Ham Listening More Fun," the article was accurate, well-written, and attracted a large non-ham audience to amateur radio. Mr. Curtis is an assistant professor of journalism at Pennsylvania State University.

There will be no 1977 competition for the Amateur Radio Biting Bug Award. However, competition will resume in 1978 in two categories. A plaque and a $200 prize will be awarded to the writer of the best article about amateur radio in an American nationally-circulated non-ham publication during 1978. To the writer of the best ham article published in a regional or local publication, there is a plaque and $100. Articles will be judged on how well they attract non-hams to ham radio. Writers do not have to be amateur radio operators.

The judge is Ray Collins, a professional writer and ham operator. Judging will be based on an article's subject matter, style, accuracy, accompanying illustrations, and the mention of where a reader may obtain more information about the hobby.

Photostats of articles with the name and date of the publication should be sent to Ray Collins WA2GBC, Harter Road, Morristown NJ 07960. Please enclose a self-addressed stamped envelope. All entries must be submitted by Jan. 31, 1979.

Kansas State Police officials have decided to do away with the traditional "10" code, in favor of simple words and phrases. "10-4" is now "okay," and "10-13" is "help, policeman in trouble." Officials report that the changeover is going smoothly, although some officers still forget and use the "10" code from habit. Reported by the AP.

FCC licensing figures released by the ARRL indicate a total of 293,655 amateurs in the states. The breakdown, as of the end of January, was: Novices — 38,365; Technicians — 61,359; Conditional — 22,483; Advanced — 71,360; and Extra — 15,732. Whether we can break 300,000 by the end of the year remains to be seen, but if current application rates continue, the chances seem good.

L.A. area repeater owners and users alike are angered by the content of RM 2844 submitted by Jones P. Talley W5JTE, which requests that the FCC place a blanket ban on closed repeaters. The majority of those opposed feel that Mr. Talley's pro-

At the March meeting of the United Radio Clubs in San Pedro CA, Dr. Norm Chalfin K6PGX spoke on AMSAT/OSCAR programs past and future. Here, as the group listens to OSCAR 7 mode B, he points out where the spacecraft is at the time. Thanks to K6SWD for the photo.

posal is an infringement upon their right to own and use personal property as they see fit and fear that once all repeaters are made open and available to any amateur, the next logical step would be to make all amateur stations legally available to all amateurs at all times. This they cite as a direct violation of the Constitution and have vowed to defeat the RM.

receive such calls may use them until they receive new calls mailed automatically by FCC. However, they are advised not to order QSLs with the WCØ call, as it will not be their permanent callsign. From the ARRL *Bulletin*.

One hundred years ago this year the

"breaker four." Gary again responds, and learns that "Main Squeeze" had blown a fuse the night before. His CB power supply couldn't quite handle the 20 Watt input radio. Fuse replaced, he is now able to enjoy the peace and quiet of the new FM-CB rig, as it is described by Gary. Gary then pretends to be interested in "Squeeze's" Cobra-200, and asks if he

was only to leave the radio beacon on the island and then continue on to Capetown. No extra effort was planned in case of poor weather . . . they would just continue on. The schedule was to be in the vicinity of Bouvet around February 24th or 25th, and this was reported when they were in Antarctica. They were early arriving at the island and were there

BE MY GUEST

visiting views from around the globe

OM Winter-East

Since the birth of radio communication, amateurs have always been there to lend a helping hand wherever and whenever disaster struck. On the last weekend of January, 1977, a different kind of a disaster struck western New York State. For the first time in history, a disaster was officially declared due to excessive snow! At the first glance, it might almost seem funny, or that people have turned soft, to be so affected by the white stuff. However, when you consider that snow fell in one amount or another every single day for over a month preceding the storm, and that, for the country as a whole, this was the hardest, coldest winter in all recorded history, it begins to take on a different proportion.

Friday had dawned dismal, like a great many days before it. Temperatures ranged from slightly below zero to five or ten above. A light dusting of snow was added to the foot or so of powder already on the ground. The weather remained stable until just after lunch. Then the storm hit. In the next eight hours, over a foot and a half of snow fell. Winds rose to 40 mph or so, with gusts over 55, and the temperature plummeted.

Before and after digging out. This house, located near the author's home, was completely buried in snow. Snowmobiles ran over the roof, the chimney (at the right end of the house) was covered over, and rescuers had to tunnel down to the door in order to evacuate the family. (Photos courtesy *Albion Advertiser*, used with permission.)

In less than an hour, the New York State Thruway became impassable. The expressways in and around Rochester were closed by the police — too hazardous to attempt any kind of travel. Other highways in the region quickly became parking lots. These were the conditions in Rochester. Further west, they were worse. My home is in Albion, the hardest hit area east of Buffalo, which of course got the worst.

Between the two cities, Rochester and Buffalo, Lake Ontario curves so that a wide bulge extends north several miles further than the rest of the lake shore. Being just on the edge of the favored intercity route, and not conveniently handy to either city, the land is mostly farmland — flat, open, and completely at the mercy of the wind. It is called Orleans County, and Albion is in the middle.

It took me four hours of creeping past stalled cars, detouring around accidents, and clawing my way through snow drifts to reach Orleans County, and I thought I'd made it. Old Man Winter second-guessed me. Five miles east of Albion, a tiny village called Fancher can be found (if you don't blink on the way through). There the State College of Brockport NY maintains a rural property for ecological research and conferences. It was just a mile west of that property that I was told to turn back. Scores of autos were bogged down ahead of me, and there was simply no passage.

I turned down a side road toward the college property, hoping to work my way around this last obstacle, and there I bogged down in a large drift. It was half a mile from my car to the

stopping in another building halfway there.

It would have been a pleasant place to be stranded, and I had good company — four cute young school teachers. Five miles away, however, trouble was starting to pile up. The XYL was stranded with a pair of stir-crazy four-year-old twins. The house is an old one (one of the oldest in Albion), and the brutal winds were forcing cold and snow in so violently that a pile of snow had gathered in a room which was separated from the outside by another room. The water in the bottom of our washer froze.

My hopes of getting out Saturday faded with the day. The snow had stopped, but not the wind. As fast as a pathway could be plowed on the roadway, powdery snow which had collected since Christmas had blown in to close it up again. Highway crews were fighting a losing battle.

Throughout the county, every high school, every recreation hall or other suitable building became an emergency shelter for the hundreds of people stranded by the storm. The CD director had to coordinate his efforts through the sheriff's office, as the CD center was all but inaccessible in the storm. All over the region, amateur radio nets were being called into emergency session. At home, pipes were freezing and bursting. Barb was thinking of evacuating to the high school.

> "With winds as high as they were, the windchill factor could freeze exposed flesh in a matter of seconds. . . "

Sunday morning I said, "To hell with this!" and started walking. The snow had packed so hard you could walk over the drifts without sinking in. My car was buried up to the window. I later heard that after one car was removed from atop a snowdrift, another was found buried three feet beneath it, the driver inside frozen to death.

I was lucky. Less than a mile from the college property, a car picked me up. The driver felt two would have a better chance of making it through than one. We zipped through one of the temporary openings in a half-mile long drift, and I saw the top of a tractor-trailer sticking out. Occasional hints were visible of cars buried in the walls of the ravine of snow. On the other side was Albion and home.

To the towns east of Orleans County, the storm was over. Highway crews trying to clear the roads had their work grind to a screeching halt as sightseers came in from adjoining Monroe Country and found themselves stranded. The sheriff finally cracked down, ordered *all* roads closed, except for official emergency traffic, and imposed a thousand dollar

chapters! I checked into the New York Public Operations Net on 75, and then notified the sheriff and the Red Cross that I was finally home and available.

The net manager, K2KQC, was stranded in Buffalo, far from her rig. W2PZL and WA2SYR were holding things together. Of course, there were plenty of others taking their shifts as net control, but these two stand out in my mind, especially WA2SYR. He's blind, but the best organized net control I've ever heard.

Fortunately, the telephones managed to hang together. Otherwise the already busy nets would have been bedlam. Throughout the day, however, I was asked to originate a few messages out of state for stranded motorists. I even managed to get some of the pipes fixed. Once again we had water running, and the wife felt better.

The CD headquarters for the entire western New York region is in Batavia, 20 miles south of Albion. There an especially energetic group was working through the 04/64 repeater. They were under the guidance of WA2AIV, who stayed several days

"The brutal winds were forcing cold and snow in so violently that a pile of snow had gathered in a room which was separated from the outside by another room. . ."

at the center, and became the first person to sleep in the bunk room since the place had been built. Bad as things were in Orleans County, we had a picnic compared to Erie, Niagara, and Chautauqua counties, which had a lake upwind which manufactured an unreal amount of snow. In Buffalo, K2DWI and others activated the station that had been installed at Salvation Army Divisional Headquarters after the 1972 floods. But I didn't keep track of them. I had troubles of my own.

Sunday afternoon the Red Cross at Medina called. A young man was in critical condition in the hospital there. The telephones were log-jammed, and they were trying to reach his kin in Rochester. For the first time in 25 years of hamming, I listed emergency traffic. I wanted a phone patch to Red Cross Divisional Headquarters, but at that moment there was nobody aboard in Rochester. One of the guys cut up to two meters and W2QYT responded, getting me through to Jim Cross, the disaster coordinator. Within the hour, the family was on their way.

Roads were still closed Monday, and were destined to remain that way through Thursday. By Wednesday, most of the nets were deactivated to a standby condition. Maybe I shouldn't admit it, but in all my years as a ham, this was the first time I had figured directly in a genuine emergency situation. Even then my contributions had been minimal — a mere drop in the bucket. I wish I could list all the guys who worked shift after shift as net control, or served as internet liaison, those who passed reams of traffic, and those who stood by and waited, but were not needed. They also serve who stand and wait.

Six days after the storm had begun, Orleans County opened the roads. Buffalo didn't open for a week or more after that. Even though I got off as easy as I did, it is easy for me to understand the bewildered, almost unreal feeling folks out this way have over the whole affair. Most of them still don't quite know what hit them. When I drove to work Thursday, it felt like I was driving down a gully, and I felt a bit uneasy. It started snowing again Thursday afternoon, and everybody beat it home. We were all scared.

Once my car was dug out of the snow, the AAA paid the tow. Getting it going again was another matter. That cost over $160. This, plus the loss of three and a half days pay, made the storm a bit expensive, but I still think I got off easy — especially in comparison to Buffalo. I guess I was little more than a bystander, but you really never know just how you'll act until the thing happens, and then, just like everybody else, you muddle through the best you can. It's only a matter of how the cards fall that decides whether you'll play a key part, or just be another drop in the bucket. Just remember — it takes an awful lot of drops to put out a fire, but they all help out.

OM Winter-West

SERVCOMM, a short title for service communications, is a group of about 100 amateur radio operators who live along the eastern front range of the Rocky Mountains from Cheyenne, Wyoming, in the north, to Raton Pass on the border between Colorado and New Mexico in the south. Recently organized (and within the American Radio Relay League public service emergency communications function), SERVCOMM has aided a remote community during a serious fire, participated in various mountain terrain rescues and, more recently, fully aided in a regional search and rescue operation occasioned by the 10-12 March 1977 gale force blizzard that struck El Paso County, Colorado, with full fury.

Amateurs answered a call for help when authorities had trouble establishing communications vital to search and rescue operations. SERVCOMM responded and filled the gap.

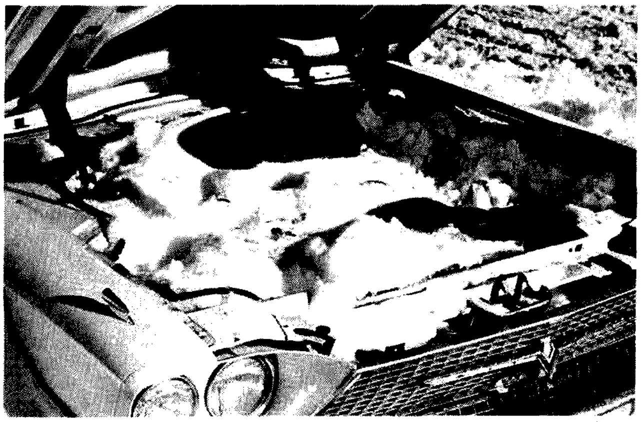
Ninety-three rescues were made by El Paso County Search and Rescue teams in close cooperation with ground and air units based at nearby Fort Carson. Amateurs rode with the various ground and air units. Equipped with battery powered two meter handie-talkies, they relayed rescue mission information to and from units in the field to a base station (WAØHFJ) set up in a motor home and parked next to the El Paso County Sheriff's office. US Army, El Paso County Sheriff, and El Paso County Search and Rescue authorities sat side by side in the "Sheriff Central" command post and directed a successful operation that saved lives and greatly reduced suffering in the afflicted areas.

The Colorado Springs two meter repeaters carried most of the emergency traffic. Primary repaters 37/97 and 16/76 were backed up with the facilities of 19/79, 27/87, and 03/63 repeaters together with thirteen SERVCOMM RTTY stations who stood by in the event the situation mushroomed.

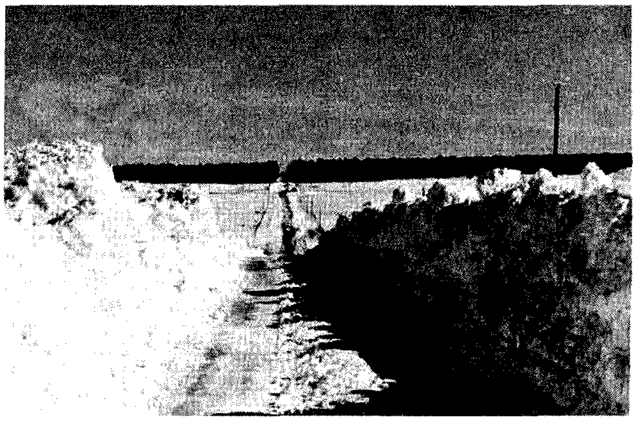
Four wheel drive vehicles were provided and operated by radio amateurs in neighborhood assistance missions. This action reduced the overall emergency problem. Among the 4 WD teams were: WA7HKS/Ø, WBØKDN, WAØLRK, WØMBZ, WBØMHP, WØMQE, WØNR, WØOQI, WBØPNX, KØROL, WBØSDW, WBØUIX, WBØWQI, and WØWYZ.

A local surgeon, WAØRGA, needed to be at an operation scheduled across the city. KØROL and WØWYX hooked up a 4 WD tandem and essentially tobogganed WAØRGA in his own 4 WD and got him to the scheduled operation in time. At the same hospital was WBØEFU, who had given birth to a fine daughter the day before. WBØEFU operated a battery powered TR-22 from her bedside and served as liaison between the SERVCOMM nets and the hospital. Various missions of transporting medical personnel to and from several facilities were completed.

WØOXR left work early as the storm rolled into the Colorado Springs area. Bound for Falcon, Colorado,



The raging blizzard penetrated everything. Those at home for days couldn't get to work.



Search and rescue operations continued after the storm, because scores of missing people, cars, and livestock had to be accounted for.

about twenty miles east of Colorado Springs, he could not see well enough to drive due to high winds and driving snow. Even the slowest speed as he groped along did not prevent him from bumping into yet another car stranded in the road. Some 35 hours later, WØOXR and eight others in stranded vehicles near him were rescued. They came through the ordeal without sleep or food by rationing fuel and maintaining two meter status reports. During the long night hours they signaled to each other with interior car lights, as head lights and tail lights were buried in snow and car doors were frozen shut. Rescuers, guided by SERVCOMM, had to battle long stretches of 15 to 20 foot snow drifts in almost zero visibility to reach them. This rescue was typical of the overall operation that employed five US Army half tracks, each carrying an amateur radio operator equipped with two meter equipment. During the last phase of the operation, when sector sweeps were made with various ground and air units, SERVCOMM continued the emergency communications service. Almost all of the emergency communications activity was captured on tape for historical record.

During ensuing days, two debriefing meetings were held with representatives of the El Paso County Sheriff's Office, Colorado State Highway Patrol, El Paso County Search and Rescue Group, US Army, and SERVCOMM present. The meetings produced 27 suggestions for improvements in the SERVCOMM operational plan so that the next time SERVCOMM is called upon, it may be in a better position to serve.

Behind all of SERVCOMM's emergency capability and potential to serve is the farsighted dedication and expertise of the Pikes Peak FM Repeater Association that has for a decade built, sited, and maintained two meter repeaters at altitudes that often provide severe lightning and arctic environments for equipment and those who voluntarily maintain them. Without this group, the loss of human life and suffering would have been much higher. Doing this, of course, is what each amateur everywhere knows to be a good measure of what amateur radio is all about!

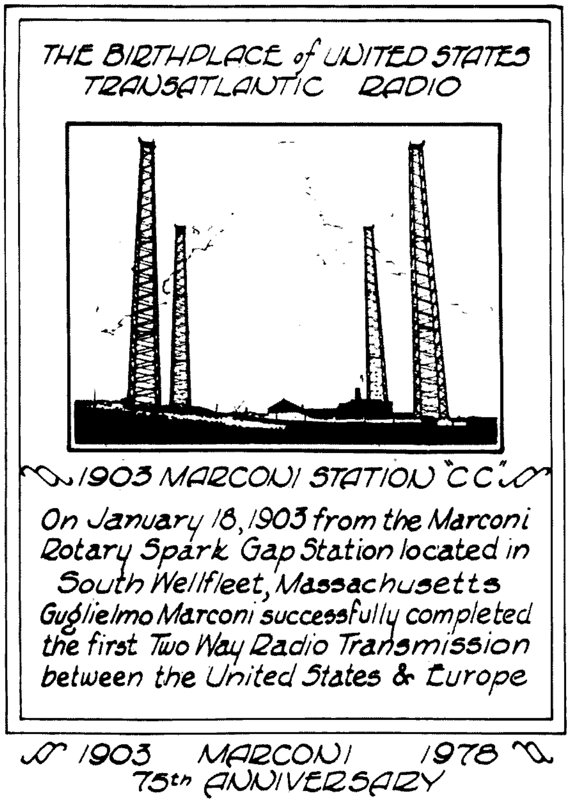
75 Years



Guglielmo Marconi came to Cape Cod, Massachusetts, in 1901 to establish the first transatlantic wireless station in the United States. The station was constructed on the sand dunes of South Wellfleet and was completed in late 1902. The transmitter was of about 30,000 Watts power, consisting of a three foot diameter spark gap rotor supplied with 25,000 volts from a kerosene generator. The aerial wires were to be supported by 200 foot masts. The masts, 20 in number, were placed in a circle 200 feet in diameter in the sand dunes. The Cape Codders were skeptical of the masts being erected in the sand dunes, and as they predicted, the masts were blown down in a northeast storm in November, 1901. Marconi then erected four 200 foot timbered towers and in late 1902 the station went on the air for tests.

On the night of January 18, 1903, Marconi attempted to send the following transatlantic wireless message from the then President Theodore Roosevelt to the King of England, Edward VII: "His Majesty, Edward VII, in taking advantage of the wonderful triumph of scientific research and ingenuity which has been achieved in perfecting a system of wireless telegraphy, I extend on behalf of the American people most cordial greetings and good wishes to you and to all the people of the British Empire. Theodore Roosevelt."

The message was received at the Marconi station in Poldu, England, and for the first time the United States had been linked with England by wireless. A return answer was received at South Wellfleet from King Edward VII and was delivered to the President through the South Wellfleet Railroad Telegraph station.

In 1907, the engineers realized that they had built the station too near the ocean, and by 1917 the sand dunes had eroded close to the tower bases. The station had to be abandoned soon thereafter. Today approximately one half of the site has been claimed by the Atlantic Ocean. In its 15 year history of operation, the station had three callsigns: CC, MCC, and WCC. Old "CC" was a prime press outlet to ships at sea and to this day WCC, now located in Chatham, Massachusetts, is the busiest commercial radio station on the east coast. The station handles worldwide traffic to and from ships at sea, and is still communicating by international Morse code as used by Marconi in his day.

During the week of January 14-22, 1978, the Town of Barnstable Radio Club will celebrate the 75th anniversary of Marconi's first two-way transatlantic radio transmission. The club will recreate this event with a multitransmitter amateur radio station operating from the original location in the Cape Cod National Seashore Park in South Wellfleet, Massachusetts. The station has received a special event callsign, "KM1CC", from the Federal Communications Commission, and will be manned by members of the Barnstable Radio Club. "KM1CC" will be capable of worldwide communications. The station will be open to the public and we hope you will come to visit us.

Jack Anderson-Nuts!

"The story charged that CBers haven't gotten a fair shake at the FCC because CB radio has traditionally been regulated by hams. . ."

The headline, from coast to coast, read: "Radio Hams Are Favored Over the CBers." National columnist Jack Anderson had scored with another hot story, and ham radio was clearly the loser.

The story charged that CBers haven't gotten a fair shake at the FCC because "CB radio has traditionally been regulated by hams." Representative Elliott Levitas (D-GA), quoted in the Anderson column, called the situation at the FCC like "the wolf guarding the flock." Figures that raised many an eyebrow also appeared, like Anderson's assessment of the frequency allocations held by 300,000 amateurs being "100 times more than available to the 9 million CB enthusiasts," plus his statement that "hams also have a lock on the higher frequencies, which are free from interference." At another point in the column, Anderson reports that "according to one confidential report, the hams now control more frequencies than all the nation's police and fire departments combined, plus all commercial and educational FM broadcasters, plus all the TV stations on the VHF channels in Los Angeles and New York City."

Anderson's column, which ap-

peared the first week of April, went on to accuse the ARRL of opposing the CB industry's attempts to gain more frequencies. And FCC Chief Engineer Ray Spence drew the biggest barb – "The Federal Communications Commission's Chief Engineer, Raymond Spence, is a lifetime member of the League. He denied that his membership is a conflict of interest."

In an interview with *73*, Spence dismissed the article as "just another Jack Anderson column." In the Personal Radio division, an aide to chief Johnny Johnston termed Anderson's conflict of interest charges "just a frivolous allegation, a typical Jack Anderson column." The aide added that he doubted that there would be any official response. As FCC sources tell it, the story got started with some of Congressman Levitas' constituents who had complained about the FCC's lack of action on Class E CB (220 MHz). The constituents, representing an unnamed Georgia CB manufacturer, wrote that they were prepared to build a plant to turn out 220 CB rigs, which would bring new jobs to the local economy. The FCC spokesman added that it was understood the EIA (Electronics Industries Association) was also lobbying Congressman Levitas on the Class E issue.

Michael Vollmer, an aide to Congressman Levitas, told a slightly different story about how the Anderson column came to be written. According to Vollmer, a constituent in Atlanta, who runs a CB factory, requested the Congressman's assistance with "an FCC problem." Vollmer refused to name the firm, or the constituent, but added that the thrust of his request was for the Congress to investigate a conflict of interest at the FCC. Several times during our *73* interview, Vollmer emphasized that his boss is not concerned with amateurs, not out "trying to get them." "Congressman Levitas," said Vollmer, "is well aware of the fine service hams have done both at home and abroad. What bothers him the most is whether a conflict actually does exist at the FCC . . . a conflict that may deny all segments of the personal communications industry an equal voice in decisions affecting it."

Vollmer, in response to a question, said that Congressman Levitas was responsible for only a small portion of the Anderson column . . . but he added that the Congressman believed most of the allegations contained in it are true. Vollmer says his boss remains open-minded on the subject, however, and is anxious to receive some feedback from amateurs. (Address those cards and letters to Congressman Elliott Levitas, 329 Cannon House Office Building, Washington DC 20515.) Levitas had already received some comment at the time of our interview, mostly from amateurs, who reportedly appealed for a chance to get ham radio a bit more credit than the Anderson column gave it. Vollmer told *73* his boss planned to deliver a speech on the House floor praising amateurs for their service, but dumping on the FCC as an ill-run bureaucracy. (Congressman Levitas has requested a formal investigation of the FCC by the House Interstate Commerce Committee.)

> "The Federal Communications Commission's Chief Engineer, Raymond Spence, is a lifetime member of the League. He denied that his membership is a conflict of interest. . ."

> "The Anderson column came at a bad time – right after a critical Federal Appeals Court decision . . ."

The FCC, meanwhile, had other problems. The Anderson column came at a bad time – right after a critical Federal Appeals Court decision that may stifle the kind of informal discussions many of us are accustomed to having with FCC personnel at hamfests and conventions. It was a cable TV case concerning siphoning, a practice that's been restricted by FCC rules. The regulation had limited cable TV operators' use of new films and sports events on their own channels, thus siphoning the programming from commercial broadcasters. The Federal Appeals Court not only threw out the anti-siphoning rule, but gave the FCC a real going-over on its rule making procedures. At issue are so-called *ex parte* contacts, discussions between FCC officials in decision making positions and parties interested in proposed rules. The court found that the FCC had violated its own rules, since the so-called *ex parte* contacts are not recorded for the public record. In future, FCC attorneys say, staff members with have to submit written summaries of their informal discussions on pending rule makings. That could mean a lot of paperwork, but more important, it could stifle the kind of "let your hair down" meetings FCC staffers like to hold at ham gatherings. Another byproduct of the court ruling is that the FCC will have to end the practice of accepting late comments on its proposals. Current procedures allow for comment after the deadline as a practical matter, since the staff rarely gets to the mail until after its own deadline.

FCC lawyers are considering a US Supreme Court appeal, but in the interim the Personal Radio Division is faced with a sticky problem – the largest hamfest in the US at Dayton. Dayton, in the words of one staffer, "is our biggest effort of the year," with five or six FCC officials planning to attend. At press time it was unclear what effect the appeals court ruling would have on the Dayton FCC Forum . . . but as the same Commission staffer put it, "at this point we can say anything we want about pending proposals, but we can't listen."

De WA3ETD

We have been getting a number of letters here at *73* concerning excessive QRM, jamming, music, etc., on the low bands, especially on 75m. Several readers complained about nets being intentionally jammed. I have not been especially active on 75, so, armed with a new linear that needed reviewing, I proceeded over to a friend's QTH for the evening. In a few minutes we were ready to go, but it required fifteen minutes to find a spot to tune up without bombing someone. Yes, the band is crowded! However, still no music or excessive QRM, and I began to wonder if the letters were a bit far-fetched. We had a few enjoyable QSOs, giving the linear a pretty good test. Then, while talking to a station in New York, I noticed someone tuning up dead on my frequency – annoying, but not interfering with the QSO. I informed the other station that "the frequency was in use," and that did it. The character proceeded to "tune up" for the next ten minutes, and it appeared that his procedure required continuous whistling into the mike while tuning. Interesting. I also noted that the higher in frequency I went, the more acute the jamming problem was. Well, I'm a believer now, and I can assure you it will be awhile before I subject myself to the "enjoyment" of 75 in the evening.

Let's face it, ham radio is in trouble. We were lucky to escape with our frequencies when the ITU met several years ago, but only a fool can hope that the upcoming WARC will leave the ham bands unscathed. Remember, the USA has only a single vote which can be countered by *any* third world country (see the "WARC Disaster" special report in Feb. *73* for details). I can imagine what an unenlightened foreign ITU representative must think when he tunes in on our low bands.

Not only is there international pressure to trim our bands, but we are also under attack from within. The CB manufacturers would love some extra spectrum space to provide equipment for, and they have an ear in Washington. A day or two ago syndicated columnist Jack Anderson (of Watergate fame) provided the media with an attack on amateur radio. The essence of his report indicated that the hams hold much more frequency space that our numbers justify, and why should three million CBers be confined to a few kHz while we hold choice "interference-free" VHF spectrum. Mr. Anderson's sources obviously are not concerned with the future of ham radio!

NEW MODES

Lately we have been swamped with articles on power supplies and mods for the new Icom 22S transceiver. These things run in spurts; next week it will probably be quad antennas or something. Unfortunately, the people most involved in tinkering have the least time to write articles. It really doesn't take a Master's degree in English to write a good technical article for *73*. If you have a pet project cooking, especially something involving the special modes such as SSTV, RTTY, or microwaves, pass along your enthusiasm to those ready to try something new. An SASE will bring a copy of Wayne's "How To Write for *73*." This document outlines manuscript requirements and provides info about photographs, diagrams, etc. Do a fellow ham a favor and "turn him on" to a new facet of amateur radio. *73* is willing to publish almost anything relating to the special interest areas of radio, so let's hear it! A point to remember: A single article can relieve the financial bite of your latest project. The other night I was talking to a well-known EME enthusiast who indicated that writing for amateur publications had just about paid for his station – think about it.

WHAT'S COMING IN *73*

Check the new RTTY feature by Marc Leavey in this issue. RTTY is a fast-moving mode with plenty of room to experiment and tinker, and if you have been hesitant to tackle teletype for want of information, try *73*.

Marc's column will provide monthly info for the beginner, as well as advanced techniques for the RTTY pro. Some good articles are coming along in future issues. A comprehensive look at active filters for RTTY is coming, written by Pete Stark, for those requiring the ultimate in terminal unit performance. SSTV will be covered in two upcoming articles, as well as an update on Stirling Olberg's "Smoke Detector" microwave system. If you need a cheap alternative to today's expensive transceivers, try 10m with a converted CB radio – coming in future issues. The new 10 GHz "Gunnplexer" microwave transceivers have been getting a workout at *73*. Watch for technical details in the next couple of issues. Tell a friend about *73*, the home of special mode articles. I'm looking for YOUR article, so get writing.

Fireworks

So you feel safe after you have disconnected or grounded the antenna feedline? Not necessarily! If you have a rotatable beam or quad, there is usually an 8 or 4 wire cable connecting the rotor mechanism with the rotor control box. This cable leads down the mast or tower into the control or operating room. Unless there is some form of disconnect between this cable and the rotor control box, part (usually too much) of the lightning surge at the antenna or tower will find its way into this cable. Very often this cable runs parallel with the coax used as an antenna feed or transmission line. This enhances the chance of capacitive pickup from the braid of the coax, since the rotor cable is usually unshielded.

In a recent case, nature added to a July 4th local fireworks display by lightning which struck the upper tip of a fiberglass quad spreader holding the 20 meter fed element of a quad at K4NE. The last six inches of the spreader disappeared, leaving a "puff-ball" of fiberglass resembling a feather duster or cotton cone such as one finds at carnivals. The eyebolt holding the antenna wire was unharmed, but dropped down since its support was lost. There was no damage to the antenna or coax transmission line.

All the antenna feeds were disconnected and grounded outside the shack. Yet the lightning surge entered the house through the rotor cable, burned out the CDR control box, entered the stripline 120 volt ac connection strip through the control box ac cord, passed into the receiver and exciter which had their ac cords plugged into the stripline, and caused considerable damage to the receiver and exciter. Some of this could have been avoided had the ac cords been disconnected. But the best preventive measure would have been to disconnect the rotor cable.

There is an eight-pin Jones plug disconnect in the rotor cable outside the shack now which can be connected to a grounding plug, all eight connections strapped together and wired to a ground rod. Truly a few ounces of prevention are worth a few pounds of replacement parts!

I just walked across the room and checked my CDR and a few other cables on various antennas, such as coaxial inverted V, etc., and boy, do I need to get busy on some protective grounding. I advise all readers to go now to your ham shack and check for proper grounding.

Lewis Sieck K4NE

Bandwidth

The widely publicized FCC docket 20777, the "bandwidth" docket, was recently commented on by the ARRL. The ARRL felt that the docket was a step too far in the "deregulation" of amateur radio, and that a "wait and see" attitude should be adopted on many provisions in the docket, such as not yet outlawing AM, and that many problems with modulated CW (MCW) in the phone bands, RTTY in the phone bands, etc., would crop up if the docket were adopted as written.

There are certainly some problems in the docket as it stands written, such as the (I think unintentional) exclusion of amateur TV from 450 MHz. But does the ARRL seriously believe that people are going to start transmitting RTTY in the phone bands, or use MCW in the phone bands? RTTY in SSB channels would be just as much of a problem to reception for the RTTY people as for the voice people. And MCW might be run occasionally for experimentation, but would be no real big problem. Has the League forgotten that there are gentlemen's agreements throughout our bands that make mutual habitation possible? How often do you hear a RTTY station outside of 14070-14105 on 20, or outside of 3600-3630 on 80? (Unfortunately, some CW stations do break this gentlemen's agreement and do intrude, but more are considerate and there is no tremendous problem.) How often do you hear SSTV outside of 14225-14235? If we receive more flexible regulations regarding the type of emissions we use, will we suddenly forget these important agreements? Will 40 years of learning go down the drain? I say no. The League has shown little faith in its own life blood, the amateur.

I don't think that the League decision rose entirely from mistrust in hams' ability to govern themselves. I think that the directors who, as a whole, formulated the League response, are long-time hams who have not been involved in the majority of the innovative new things happening in our hobby. To them the status quo is just fine, so "don't rock the boat," let's just wait and see, and join our buddies for a rag chew on whatever mode. The experimenter has been left out in the cold!

The League is us, it's the greatest thing going for us in amateur radio, and the League is concerned about the members' views. That should be obvious from the Docket 20282 survey, which also shows that the members are concerned about League policy. If you agree with me that this issue needs another look, the first step is to be sure you are an ARRL member. Then let them hear your ideas, whether they agree with mine or not, so that they can adhere to member wishes. The League is us.

Insurance

Listening on 2 meters during recent months, I have heard numerous discussions about the problems of insuring amateur gear, particularly with regard to 2 meter mobile and hand-held equipment. There seems to be much misinformation going around, especially since there are numerous ways an insurance company may look at equipment and its situation in the mobile.

Radio gear may be insured in several ways. First of all, equipment which is permanently installed in the home is considered as household contents and should be insured against such perils as fire, extended coverage, vandalism, and theft, along with other personal property under the well-known homeowner's insurance policy. It is, in fact, automatically covered by this policy, usually subject to a $50 or $100 deductible clause.

Other equipment, such as mobile rigs, hand-helds, or otherwise portable gear, is best insured through Inland Marine Insurance.

The National Association of Insurance Commissioners has ruled under what is known as the Nation-Wide Marine Definition that ham radio equipment in automobiles and otherwise not permanently located in a structure qualifies as a subject for Inland Marine Insurance. Such coverage provides protection against all risks of physical loss or damage except for specified perils such as war, nuclear explosion, infidelity or damage while being worked on, and a few others, wherever located, worldwide.

Insurance may be provided by endorsement to your homeowner's policy just as your cameras, jewelry, furs, or musical instruments can be insured under a personal articles supplement. The rates are generally the same as for musical instruments or cameras. Should you not carry a homeowner's policy, you can purchase an Inland Marine policy known as a Personal Articles Floater on the same basis and providing the same all risk coverage.

It is well to have purchase invoices or other documents to verify values and, as the prices of equipment go up, your insurance should be likewise increased to reflect replacement value. Even though replacement at the time of the loss may be on a depreciated basis, depreciation is based on replacement cost at the time of loss and not on original cost.

The third possibility for insuring your mobile gear is as a part of your automobile policy, which may work against you at the time of loss. Should you elect to insure your gear as part of the auto, it would be well to take a Polaroid photograph of the rig installed in the car and have your agent inspect it and give the insurance company a statement along with the photo to the effect that it is a permanent installation.

When insuring your equipment, always use an itemized schedule giving a full description of all items, including crystals, serial numbers, if any, and *current* replacement value.

In spite of the feeling of many who say nasty things about insurance companies, if you insure properly and give full information at the outset, you will be treated fairly when a loss settlement is made. Should there be honest differences, you always have recourse to your state insurance department which is charged with the responsibility of assuring equitable

handling of honest claims. Just don't try to get something you are not entitled to and, by all means, read your policy as soon as you receive it and take up with your agent anything not clear.

There remains one other area of insurance which, in recent years, has become of great concern to some amateurs. This is the area of lawsuits arising from real or imagined intrusion by amateurs into the rights of privacy of others. Much has been written and voiced about the need for such protection, but apparently, few people know that such protection is readily available and some probably already have it.

Insurance companies have, for many years, offered what is known as "Umbrella Liability Insurance" which is catastrophe type protection for a person's legal liability arising from his negligent acts. You are aware of the automobile bodily injury and property damage insurance, which is now a requirement in most states, and the personal liability protection, which is Section II of a homeowner's policy. An Umbrella Liability policy covers above these policies and also covers other areas of exposure above what is known as a Self-Insured Retention, usually \$250 to \$1,000. Areas covered by the Umbrella, which is usually issued for \$1,000,000, include "invasion of privacy," such as might arise from interference by an amateur station with home entertainment equipment, television, radio, or telephone. The Umbrella policy provides cost of legal defense, as well as paying judgments for which the policyholder is found liable, up to \$1,000,000 above the amount of the Self-Insured Retention which he must bear. Such policies are easily obtained and are relatively inexpensive. If automobile insurance is carried with limits of \$100,000 per person, \$300,000 per occurrence for bodily injury, and \$25,000 per occurrence for property damage, and if personal liability of \$50,000 is carried, an individual with one dwelling and one auto can usually obtain umbrella protection for under \$100 per year. Many larger businesses provide this coverage as an employee benefit at substantially lower premiums.

The insurance coverages we have discussed are readily available throughout the US and Canada. Any professional insurance agent should be able to properly insure you as a radio amateur in a short time if you sit down with him and give him the information about your equipment and operation we have discussed here. Who knows, in addition to properly protecting yourself, you may at least get the real story of amateur radio to someone else or find a budding ham.

Leonard Fowler Jr., CPCU, WA3TCE
Bryn Mawr PA

Another Milestone

Although few hams would agree, one of the best things that has happened to amateur radio has been the advent of the Citizens Radio Service, or CB. From the beginning of radio communication, the amateur service was a non-commercial user of radio frequencies and the word "amateur," denoting unpaid, inexperienced, or unskilled as compared to "professional" or full time, most certainly required strict regulations to protect the public interest up and down the radio spectrum. Like the new automobile driver, this amateur must prove to the Federal Communications Commission that he or she has sufficient radio knowledge by personal examination to put a signal on the air. Thus, the various types of amateur licenses have evolved over the years and the ham can even build and operate his own equipment.

On the commercial side, it was later shown that unskilled persons such as police, firemen, taxi drivers, pilots and others could successfully operate communications equipment that was government type approved and both installed and serviced by licensed persons. When the equipment meets quality standards and is adjusted by qualified personnel, it is evident that the technical knowledge and skill of the operator becomes less important. This latter concept could have paved the way for the CBers.

At least for the first time persons over 18 years of age could get on the air without examination merely by application. Even low power handheld units can be operated without any permit or restriction. Without doubt, the success of CB has exceeded all expectations. Not too many years ago, the radio enthusiast was asked, "Are you a ham?" Now, they nearly always say, "Do you have CB?"

The demand for CB equipment has created a bonanza for electronics manufacturers. Many new companies that jumped aboard the bandwagon have also taken a look at the much smaller (but more expensive) amateur market since the same production techniques apply. Competition has probably reduced the price of some ham gear over what it would be with fewer manufacturers. The sheer numbers of builders stand out when comparing the advertisers of 10 or 15 years ago with the present.

It may be a coincidence that the proliferation of CB has prompted the Federal Communications Commission to take a concerned look at the amateur regulations from time to time. Recent changes like elimination of special Novice calls, no advanced notice of extended portable operation, relaxed logging requirements, and others, have reduced paper work for the FCC. When your hands are full and your budget's under review, the only alternative is to look for ways to lighten the load.

Most certainly the spotlight has shifted to another milestone in radio communications. Has the Citizens Service been beneficial to amateur radio? Some amateurs are beginning to think that it has.

Strip Your Shack

In my attempts to recruit people for our hobby, I have met with concern regarding the cost of equipment — fears that people could not afford to venture into ham radio or to convert from CB.

This is a fallacy which must be corrected by our own publications and should be put into its proper perspective. It is high time that our hobby rags publicize, via the media, that ham radio equipment is really no more expensive to the Novice than many CB rigs.

Many wrong impressions are created when we invite a would-be Novice to our shacks, where we may have a fantastic array of gear. Do you confess to him that this or that piece of equipment is oh-so-many-years old? That it has already been robbed of so many parts that it is now useless, and can never be used again except for further pilfering of parts for another project?

Stop this bull! Be honest with yourself and with him. If you cannot remove the excess gear from his sight, then, for goodness sake, at least label it as obsolete. You will feel and he will feel more at ease. For that reason my shack is stripped to the bare essentials.

It is a warm feeling to have a youngster say: "Gee whiz, is this all you really need to work across the world?"

You answer, "Yes. Control yourself, Mister. Sit down and I shall endeavor to show you exactly what I mean. New Zealand is now busy with WA6 on 15 meters but, just as soon as they complete their QSO, I will demonstrate an attempted contact."

Good fortune came my way with propagation, sunspots, and opportunity, and Frank ZL1BDG answered me. Thank you, Frank. I made a convert.

This young man is now asking me, "How quickly, how soon, and . . . maybe I can use the money from my paper route."

Of course he does not understand the CW yet, but, with my persistence and influence, he will.

In most photographs with the proud owner/operator posing in his shack, I see items of equipment which are not really necessary to operate a bona fide station. Remove that excess gear, OM, and enlist a recruit.

Only after we make it a practice to remove excess gear can we hope to initiate or convert people into our ranks. The display of expensive equipment scares the hell out of them. Move out the crap and you will note an immediate and gratifying change of attitude.

I would like to upgrade my equipment, but looking over price indexes I nearly jump out of my pants. How does a prospective Novice feel when he or she perceives the staggering sums demanded by the makers of today's boxes? They are turned right off!

Forty-nine years ago, fresh from radio school, I was escorted into a destroyer force radio shack and was told I had to learn to operate the equipment. I nearly panicked.

But I learned a compatibility with those ten inch high, five inch diameter bottles, which we later learned to call tubes. Those "bottles" though, were Uncle Sam's investment and not mine . . . all I had was patience, and I could afford to learn to live with them, and them with me.

Today's people, though, do not have this patience. Everything must be now! It's something else. More results more quickly, and more demands. I sympathize with them. They are the ones who will invest in the equipment, and if you would help steer more hams our way by stripping your shack of junk in order to show them just how little is needed to operate your station, we'd all be better off.

CLEGG FM-76 220 MHz TRANSCEIVER

Something has got to give on 2m FM. The band is getting so crowded in the big cities these days, that finding a clear pair is next to impossible. Even up here in New England, where terrain has long allowed local repeaters to coexist with their big city neighbors, overcrowding is becoming the order of the day. The reason? There are more amateurs active on 2m FM than all the other ham bands combined!

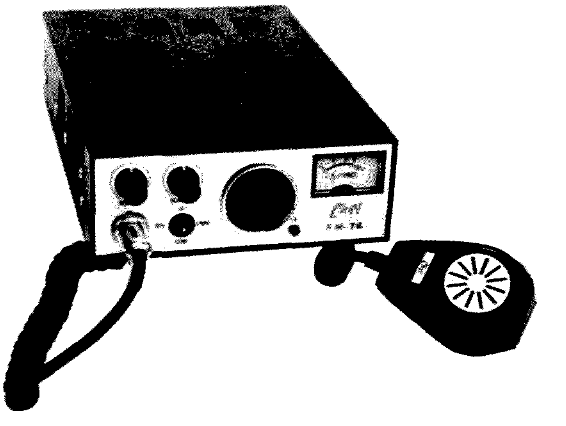
The movement up in frequency hasn't been as fast as many predicted. Repeaters (and simplex use) up on 450 MHz are growing slowly but steadily, fueled by easily modified surplus commercial gear and 2m control links. The growth pattern has been for groups to add 450 repeat capabilities after establishing the 2m system and sorting out a 450 control link. It is only natural, then, to go repeat on the higher band. But for a number of reasons this pattern hasn't happened on 220 MHz, the middle ground between 2m and 450.

"Use it or lose it" was the battle cry when the CB interests first started eyeing 220, and considering recent statements of a few CB manufacturers and coverage in the national media on the subject, it looks like the battle may have only just begun. FCC engineers have tested 900 MHz for CB purposes, and agree that's the place CB ought to go. Getting the whole Commission to agree may be another matter, in view of the 220 CB advocates, but at least the 900 MHz tests are a start. Another positive development is the marketing of low priced 220 MHz transceivers, and the resulting growth in 220 activity.

Activity on 220 is certainly up, especially when you consider a 50 percent increase in 220 repeater listings in the *73 Repeater Atlas* between 1976 and 1977. We are quite far away from having a 220 machine in every state, but few big cities are now without them. Another year of growth on 2m at current rates, and 220 may well become the best alternative for new repeaters. The two bands are pretty similar, with comparable propagation and antenna systems. The major difference is the lack of crowding on 220, and thus the easy availability of coordinated frequencies for repeaters. One interesting sidelight is that New England DXers have joined 220 systems, crossbanding them down to 2m in some cases, to provide a DXalert system stretching from Maine to Connecticut. All those arguments for getting on 220 aside, one of the best reasons is economics, pure and simple. What other band can you get onto for less than $200? That's new, not surplus gear!

An excellent buy, at this writing, is the Clegg FM-76 priced at $165. If your club buys in quantity (from 2 to 40 at a time) the price can go as low as $140. A call to Clegg's toll free telephone number (800-223-0250) will connect you with some more specific information on group prices and related group purchases.

The FM-76 is basic in concept, a feature I'm glad to see after testing so many 2m FM rigs overloaded with buzzers, bells, whistles, and gadgets. The simplicity is a bit misleading, however, when you consider that all the essentials (and a bit more) are there. Clegg has included receive and transmit crystal trimmers, remote speaker jack, power output switching (10 W to 1 W), a transmit indicator, a large illuminated S-meter/output meter combo, a more than adequate built-in speaker (side-mounted, not top- or bottom-mounted), and rear panel inputs for tone burst and output for a discriminator meter. The Clegg is rugged, with a strong and easily-mounted mobile bracket arrangement. Rear panel connectors are standard SO-239 for coax, with a four pin mike connector for the tone burst and discriminator connections. The FM-76 is small, and space was found in my sports car despite the presence of several other radios and a cassette deck. (I even had room for my wife left over!)



The Clegg FM-76 — 10 W on 220 MHz for a moderate price.

The layout, as can be seen in the photo, is simple and clean. Channel numbers are large and well illuminated, and the radio is very easy to operate mobile, day or night. Twelve channels are allowed for, with the 223.50 MHz simplex pair already installed, as standard equipment, at the factory. Clegg nets additional channels for $8 a pair, when ordered at time of purchase. Even here in New England, where we are lucky enough to have quite a few 220 repeaters, I was hard pressed to fill all 12 channels. I ended up with six repeater pairs and the simplex channel.

As this review was being prepared, winter was finally ending here in New Hampshire. So what better excuse for a climb up nearby Pack Monadnock Mountain, the official *73* test site? The mountain comes to just over 2300 feet above sea level and is better known as "Mt. Intermod" because of its uncanny ability to demoralize the best transceivers, turning their receivers into scrambled eggs . . . a maze of cross modulation, intermod, and desense. The mountain is so well located that scores of contests have been won from its peak, the site for several years of the WR1AAB repeater. This mountain, in a word, is a bear.

Getting up the mountain is a lot easier than you'd think. Since the area is a state park, a paved road is maintained during the warmer months. Our test crew was prepared with not only the Clegg FM-76 for 220, but also with some 2m radios, just for comparison purposes.

The comparison was incredible! The 2m band was a mess, with (count 'em) 4, even 5 repeaters on the same frequency in some cases. Not even going down to 1 Watt would cut the QRM. Simplex operation quickly became the only alternative, and 52 got quite a workout.

While the others worked on 2m, I set up on 220 with the Clegg. I used a magnetic mount Antenna Specialists 5/8 wave antenna. Our test rig has been factory equipped with a half dozen repeater pairs. I started out with 224.34, easily raising the Fitchburg MA repeater, and Ed K1SSH. Then we switched off to 223.50, the recognized national 220 simplex frequency. Ed was loud and clear, but soon there was a mini-pileup! (Who says there isn't activity on 220?) Five stations were worked, ranging from Acton MA to Derry NH. I was able to access four other repeaters, including Waltham MA, Quincy MA, and Chester NH. All were Q5, most of them DFQ. Activity, however, was not exactly heavy. It was difficult to get QSOs, despite the noon timing of our trip up the mountain. To say the least, it was a bit discouraging.

I began to feel better, though, as soon as I switched back to 146.52. Bedlam! The boys had quite a pileup going, and some of the stations on frequency were pretty upset — breaking the channel for a "local QSO" only . . . no DX! (It reminded me of a W2 station on 75m who used to call "CQ CQ, no kids, no lids, no space cadets who got their tickets off the top of a cracker jack box!")

Back to 220. I learned from K1SSH, via the Fitchburg machine, that activity there was up, that they were doing even better than the big Boston 220 repeaters. Another station disagreed when I QSYed to Waltham on 223.34, but it was nice to hear an argument about *increasing* activity on 220 . . . instead of the usual "use it or lose it" philosophy.

On the way down the mountain I struck up a simplex QSO with a Manchester NH station, and as I listened on the 2m rig, my companions (in another mobile) were also working a Manchester station. Both of us were running compatible power and antennas, and reports coming back on 2m and 220 MHz were about even, respectively. Interestingly enough, both of us lost our QSOs at the *same* point — just as we drove off the access road. It was a graphic demonstration of the surprising similarity in propagation on the two bands.

All through this, the Clegg worked flawlessly. The receiver was not affected by the strong rf fields generated on the mountaintop by several commercial repeater installations. It was easy to squelch out overload from my 2m rig, even when running a 70 Watt amplifier, without tightening up beyond the ability to hear anything through the Clegg. And audio reports off air were good, with the comments indicating sufficient deviation and audio gain.

Power output was measured in excess of Clegg's specs, with about 11.5 Watts out in the high power position, 1.5 Watts out in the low power mode. By fooling with the Antenna Specialists 5/8 wave, I was able to get the swr beyond 3 to 1, but the Clegg reacted only by reducing output in direct proportion to the increase in swr. A direct short was then set up, but no smoke! The Clegg, as outlined in the owner's manual, simply refused to transmit.

In the ham shack, the Clegg ran very well off a car battery, and played a key role in gaining several new ones during the late winter DX contests. If you never have used a DXalert repeater system, you're in for quite a surprise — it's really great to know what's happening where, and when. And when it comes to DXalert machines, the movement is growing the fastest on 220.

So, the next time you're driving home in the afternoon rush hour, waiting your turn on 2m, give some thought to 220 MHz. Wouldn't it be nice to actually have a QSO on the way home, instead of finally getting it turned over to you just as you turn into the driveway? You bet! And when you do decide to join the rest of us on 220 MHz, consider the Clegg FM-76. It is small, well built, works without any glitches . . . and the price *is* right. *Clegg Communications Corp., 208 Centerville Road, Lancaster PA 17603.*

The Heathkit HR-1680 Receiver.

The Kenwood R-300 general coverage receiver.

HEATHKIT HR-1680 RECEIVER

With the advent of the HR-1680, the folks at Heath have again surpassed themselves by making available to the newcomer as well as the seasoned operator an inexpensive yet very versatile ham band receiver. It is difficult to believe that a receiver with such sensitivity and design can still be purchased for as little as $199.95.

The cabinet, which measures 12¾" x 6¾" x 12", is in the traditional Heathkit green to blend with your existing station. The dial and S-meter are behind the newer style red dial window so they can only be seen when the receiver is turned on. The knobs are traditional Heath except for the main tuning knob, which includes a convenient finger spinner for fast frequency changes.

Going into the receiver, the construction is completely of solid state design. Four printed circuit boards make up the entire unit and each is inserted into its own socket. These can easily be removed for servicing and during initial tune-up.

Construction progressed in the normal Heathkit style with simple straightforward instructions and easy to understand diagrams. The entire building of the receiver, including tune-up, took approximately four nights of work or a total of about 16 hours. Tune-up is as easy as it could possibly be – no external equipment is necessary. However, the use of a VTVM and rf generator may improve the sensitivity to some extent. I did not notice any appreciable difference in the two methods of alignment.

The receiver covers the following frequencies: 3.5-4.0 MHz, 7.0-7.5 MHz, 14.0-14.5 MHz, 21.0-21.5 MHz, 28.0-28.5 MHz, and 28.5-29.0 MHz. Upper sideband, lower sideband, and CW modes are selected through the use of a front panel slide switch. A 100 kHz crystal calibrator is included for instant calibration of the receiver on any band.

A four pole crystal filter is provided for SSB reception, while audio filters narrow the audio response to either 2100 Hz minimum at 6 dB down for SSB or 250 Hz minimum at 6 dB down for CW. The maximum filter response is 7 kHz at 60 dB down for the wide position and 2.5 kHz at 60 dB down for the narrow position.

The sensitivity is claimed to be less than .5 microvolts for a 10 dB signal-plus-noise ratio for SSB operation. I compared the receiver to the receiver in the popular Heathkit HW-101 transceiver and found the sensitivity to be much greater in the HR-1680 while using the same antenna and switching it from one receiver to the other. The dynamic range is listed at 120 dB or greater.

Operation of the receiver is very simple. Front panel controls include af gain/power on/off, preselector tuning, rf gain, main tuning, bandswitch, function switch (narrow and wide filter and calibrate), and a mode switch (LSB-USB-CW).

The back panel includes jacks for a 4 Ohm speaker, a sidetone input from your transmitter, muting, antenna, and 13.8 volts should the receiver be run from a car battery or external power supply.

The possibilities for a receiver such as this are almost unlimited. Besides its obvious use as a primary station receiver for both the novice and the advanced amateur, it can be used as an auxiliary receiver with a transceiver for split operation. A little ingenuity on the part of the purchaser will also find many other uses for a receiver such as this around the shack.

Also available is a matching speaker, HS-1661. The speaker has an impedance of 4 Ohms and its response is tailored to SSB reception. For the additional cost of $19.95, the speaker is an excellent value to round out your HR-1680. *Heath Company, Benton Harbor MI 49022.*

KENWOOD R-300 RECEIVER

The parade is on! After a long drought, the electronics marketplace is being provided with an excellent choice of moderately priced communications receivers. For the past few months *73* has been reviewing this new crop of receivers, and this month I had the pleasure of checking out the R-300 by Kenwood.

The R-300 is of "classic" design, as there are no phase locked loops or other devices employed in the tuning scheme. The Kenwood tunes continuously from 170 kHz to 30 MHz, with the exception of a small gap from 410 kHz to 525 kHz. Bandspread tuning is provided for three of the six ranges, starting at 3.0 MHz. Both of the tuning dials are of the drum variety, controlled by large knobs with "rapid-twirl" indentations. A six position bandswitch controls the range, which is indicated by a green semaphore that appears next to the selected range. A combination of push-button and rotary controls round out the available operator functions. Two-position buttons control power, crystal calibrator, and panel lamp, as well as mode, noise limiter, and tone selection. The antenna trimmer, audio and rf gain, and BFO are conventional rotary controls. All functions operate smoothly, and the tuning and bandspread are without whiplash. Back panel options consist of speaker jack, antenna connections, external battery jack, and i-f module adjustments. An S-meter zero control is also provided.

This receiver functioned well on the test bench. A longwire antenna as well as the Kenwood-provided random wire were used during the test. Sensitivity is good on all bands; however, a preamp would be required for serious work on ten meters. On the other end of the dial, the sub-broadcast range was interesting. VLF enthusiasts will be pleased by the R-300, as any number of code, weather, and information stations were copied in the 170 kHz band. The crystal calibrator was most useful when calibrating the main tuning and bandspread. The main tuning can be roughly set to allow bandspread tuning, then tweaked exactly on frequency by listening for zero beat after the 'spread frequency is set. Bandspread scale increments are 20 kHz, and can be easily subdivided by eye. The BFO is stable, and it was easy to tune SSB signals accurately. My impression is that the R-300 could serve as a backup receiver for the advanced ham or Novice operator.

The Kenwood R-300 is priced at $239, a price that should interest serious SWLs and the amateur in need of a second receiver. The battery option makes it a natural for the summer season that is finally arriving. The receiver is a good value, as it is unusual to find a calibrator and full complement of controls on a rig so reasonably priced!

A GUIDE TO 2M SYNTHESIZERS

When the first repeaters were developed, they were few and far between. Any given area had only one repeater and only the more enthusiastic amateurs modified their converted commercial FM transceivers to provide for a simplex channel as well as the local repeater channel. The first transistorized transceivers designed specifically for the two meter band had provisions for three channels, deemed generous in the early days. Soon, however, the availability of relatively inexpensive transceivers and the multiplication of repeater installations created a demand for 6, 12, and even 22 channels in the transceivers.

With 22 channels (some areas support 22 or more repeaters), the cost of crystals becomes a major factor. At $5.00 a crystal it could cost over $200 just to fill all the positions in the transceiver, and even then you would not have the flexibility needed in some areas of the country. To move to another area could be a financial disaster.

More and more amateurs are turning to synthesizers to solve this crystal problem. The manufacturers have come out with a variety of adaptors and complete rigs which eliminate any need to buy lots of crystals, and which will access almost all repeaters and all simplex channels.

This article is designed to summarize the important characteristics of most of the synthesizers available for two meter FM. Only FM (and not the allmode) rigs are considered here.

Table 1. List of synthesizers and synthesized transceivers.

Equip.	Range (MHz)	Offsets	Stab. (ppm)	Temp. (°C.)	Spurs (dB)	Power	Wt. (lbs.)	Size (in.^{3})	Xceive	Cost
1. Amcomm	143-149	R + S[1]	10	-20 +60	60			187	Yes	500
2. B'stone 144	143-150	S + all	10	-11 +54	70	High	8	313	Yes	480
3. SC 1800 M	145-148	R + S + 3[2]			60	Low		67	No	225
4. CE 2001[3]	146-148	R + S	20	0 -38	45	Low			No	300
5. Clegg FM-DX	143.5-148.5	R + S + 3	5	0 -50	66	High	7	262	Yes	600
6. MFA-22	144-148	R + S + all	5	-10 - ?	?	High		137	No	300[4]
7. Mid 13-510	144-148	R + S + 2						171	Yes	390
8. GLB 200	146-148	R			60	Low			No	260
8. GLB 300	144-148	R + S	5	-10 +50	60	High		79	No	135K[4]
8. GLB 400B	144-148	S + all	5	-10 +50	60	High		111	No	150K[4]
9. WE-800	144-148	R + S				Low	2	102	Yes	390

14. Vanguard	Any 10 MHz	none	5	-10 +60				36	No	160[4]
15. KDK FM 144	144-149[7]	R + S	20	0 -50	60	High	5	104	Yes	390
16. HW 2036	144-148[7]	R + S + 1	15	-10 +50	50	High	6	223	Yes	270K
17. VHF/ONE	144-148	R + S	2	-10 +50	60	Low	4	160	Yes	350
18. Yaesu 200R	144-148[7]	R + S[8]				High	7	247	Yes	450[9]

[1] ± 1 MHz also available.
[2] Special Channel Memory.
[3] For use only with a Motorola HT-220, and fits inside omni case.
[4] Costs less without 5 kHz capability.
[5] Any 22 channels.
[6] Programmable for any split; will automatically scan band.
[7] Will cover only 2 MHz without retuning.
[8] No 5 kHz spacing available.
[9] No longer in production; some units available from Amateur Electronic Supply for $300.

A description of these rigs is given in Table 1.

An explanation of the columns in that table is given here.

Col. 1 – Lists the name of the unit. The number refers to the manufacturer or main distributor, with address and telephone number, in Table 2.

Col. 2 – Lists the frequency range covered by the synthesizer.

Col. 3 – Lists the various offsets available. R stands for plus and minus 600 kHz. S stands for simplex. The number of switch-selected offsets is also given. *All* implies that the transmit and receive frequencies can be independently selected and hence cover any repeater split.

Col. 4 – Lists the frequency stability in parts per million (1 part per million implies a frequency uncertainty of about 150 Hz at two meters).

Col. 5 – Lists the temperature range, in Celsius degrees, associated by the manufacturer in the specifications.

Col. 6 – Lists the degree of suppression claimed for spurious frequencies (not harmonics).

Col. 7 – Indicates the power consumption of the synthesizer. Those labeled low are usually based on CMOS ICs and will consume less than 10 mA.

Col. 8 – Lists the weight of the unit in pounds.

Col. 9 – Lists the size of the unit in cubic inches.

Col. 10 – Differentiates between synthesizers alone and synthesized transceivers.

Col. 11 – Lists the costs of the unit, with a K indicating the cost of an unassembled kit.

If no entry appears in any column, it means that the manufacturer does not establish a value for that quantity or that information was not available when the table was prepared.

There is a lot of information in the main table; however, there is a lot of important information which cannot be given in any table. Quality of construction is one type which is impossible to objectively present. The completeness of instruction manuals and the availability of service has not been considered. Neither have the terms of any warranty or the reputation of the manufacturer. Few companies will tell you how long it takes a unit to lock onto a frequency. If any unit has special features of great significance, a footnote to the table so indicates.

Some of the columns will be of greater interest to some prospective buyers than to others. At the present time, there is not much FM activity below 146 MHz. Hence it is of little importance to most amateurs whether the synthesizer covers 145 MHz or not. But 144-145 MHz coverage is of great importance if the transceiver is to be used overseas in areas where repeater activity is below the US frequencies. Furthermore, if the repeater to be used is a MARS repeater, the synthesizer must cover the frequencies just outside the two meter band.

If your area contains no repeaters with an oddball separation, you need not be concerned about any offsets other than the regular 600 kHz up and down and simplex. But, if you travel a lot, the availability of a nonstandard offset might be important.

The next three columns have to be treated with a certain amount of skepticism. Here there is a lot of room for specmanship. The definition of stability at one company may not be the same at another. This difference in definition is particularly important when considering a quantity like spurious output. The Heath company, for instance, lists their spurious output as better than 70 dB down within 20 MHz of the carrier, but only 50 dB down if one goes further away. Another company might just forget about those spurs at the greater distances from the carrier. Heath claims only 40 dB of suppression for harmonics. It is safe to say that most of the other companies could not apply their spurious suppression claims to their harmonics either.

The power consumption will be of interest only to those who contemplate battery operation away from an automobile or other charger – as with

an HT, perhaps. The power consumption is basically a function of the complexity of the circuit and whether the ICs used are of the CMOS (low power consumption) or TTL (relatively high power) type.

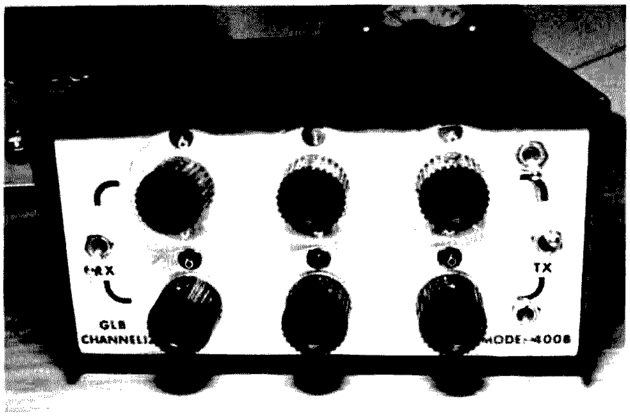
Size may be a limiting factor if the unit is to be added to an existing mobile installation or if the available space is small.

Most of the units listed are complete transceivers, but some are designed to replace the crystals in existing rigs. No attempt has been made to indicate with which rigs the various outboard synthesizers will work. The best way to find out if a given unit is compatible with your particular rig is to write the manufacturer whose synthesizer you are considering.

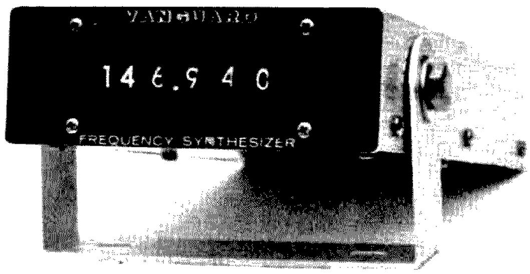
Of course, everybody is concerned with the price. Like calculators, the price has been coming down, and I expect that trend to continue. But I know of nobody who will predict how far down the price of a good rig will go, or how fast the price will fall.

There have been advertised two synthesizer-related pieces of equipment worth mentioning. Engineering Specialties (Box 2233 Oxnard CA 93030, phone 805-486-0817) has offered a Synthacoder for $87.95. This unit is designed to plug into the Icom 22S to permit any channel to be dialed into the Icom by thumbwheel switches. Thus, the owner of that rig would no longer be limited to the 22 channels usually provided by hand-wired diodes.

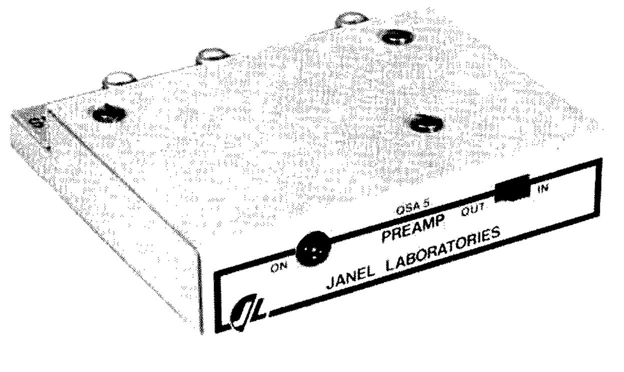
The other interesting unit is offered by Amateur-Wholesale Electronics



The GLB Model 400B.



The Vanguard Synthesizer.



The Janel Labs QSA 5 preamplifier, which can handle up to 30 Watts of transmit power through automatic switching.

(see number 15 in Table 2) for owners of the KDK FM 144. The FMSC-1 Scanner plugs into that rig and permits it to automatically scan a selected 1 MHz portion of the two meter band. Its introductory price is about $170, and it is easily installed.

Of course, this newest segment of the two meter FM market is changing rapidly and new products are coming in faster than old products are disappearing. But the tables presented here should give you a good idea of the variety of equipment presently for sale, as well as some idea of the state of the synthesizer art with which to compare any new equipment that you come across.

Alex F. Burr W5QNQ
Las Cruces NM

EDGECOM SYSTEM 3000

Edgecom of Torrance CA has announced a new microprocessor-based 2m transceiver. The new rig features programmable priority channels, monitor alarms, a built-in scanner, subaudible tone encoder/decoder, variable frequency offsets, and push-button frequency control. Output is adjustable up to 25 Watts from 1 Watt. The System 3000 will sell in the under-$500 price class. *Edgecom Inc., 2909 Oregon Ct. #A3, Torrance CA 90503.*

70 WATT, FM/AM/CW/SSB 2 METER AMPLIFIER

A new 70 Watt, 4 mode, 2 meter amplifier has been introduced by VHF Engineering of Binghamton NY. This new amplifier, the Blue Line BLC 10/70, is designed to be used with the popular 10 Watt FM transceivers and the popular multimode transceivers in the 5-15 Watt class and will deliver 70 Watts output in both the class C mode and the linear mode. A front panel switch permits simple selection of class C or linear mode. An additional model, the Blue Line BLC 2/70, offers the same features as the BLC 10/70 but will operate with transceivers or transmitters in the 1 to 2 Watt class.

The VHF Engineering Blue Line series of amplifiers have been designed for reliability and long life and feature unique broadband, stripline designs, which require no tuning or adjustment during their lifetime. Automatic sensing and relay switching are provided to automatically switch the amplifier into the circuit when drive is applied in the class C (FM) or linear (SSB) modes. The amplifiers offer high efficiency and introduce a receive insertion loss of less than 1 dB. They are designed for 12-14 V dc operation in base station or mobile service. *VHF Engineering, 320 Water St., Binghamton NY 13902.* The BLC 10/70 sells for $139.95 and the BLC 2/70 sells for S159.95.

NEW 80 WATT, LINEAR/CLASS C, 450 MHZ AMPLIFIER

A new broadband, high efficiency, 4 mode amplifier for the 420-450 amateur band has been introduced by VHF Engineering of Binghamton NY. This new amplifier, the Blue Line, BLE 10/80, will deliver 80 Watts output in either class C or linear mode with a nominal 10 Watts input. It is designed as an amplifier to be used with FM, AM, SSB, or CW rigs in the 10 Watt class. A similar amplifier, the Blue Line BLE 30/80, is designed to be used as an amplifier for rigs in the 30 Watt class.

The Blue Line series of amplifiers from VHF Engineering are high efficiency, broadband, stripline amplifiers, which have been designed for long life and reliable operation. Because of their unique, broadband design, they contain no tunable or adjustable components. Tuning or adjustment will not be required during the lifetime of the units. Automatic transmit/receive switching is provided through the use of sensing circuitry which detects the presence of drive power in either the class C (FM) or linear (SSB) modes. They are designed for 12-14 V dc operation in base station or mobile service. *VHF Engineering, 320 Water St., Binghamton NY 13902.* The BLE 10/80 is $289.95 and the BLE 30/80 is $259.95. Both units are wired and tested.

JANEL LABORATORIES MODEL QSA 5 PREAMPLIFIER

A new two meter preamp has been introduced by Janel Labs. This preamp is specially designed to improve the sensitivity of transceivers and includes all necessary bypass circuitry for carrying transmit power through the unit. The low noise figure of the preamp gives excellent sensitivity for weak signals. An adjustable delay circuit (similar to that used in VOX circuits) allows for use on all modes – FM, SSB, AM, and CW.

The gain of the QSA 5 has been optimized for transceivers. The 15 dB gain level is sufficient to improve the sensitivity as much as is practical, but low enough to avoid creating unnecessary overload problems.

A front panel switch is included on the QSA 5 to disable the preamp from the antenna line. This allows one to cut the gain on local signals and also allows for experimentation on weak signals. A LED pilot light is used to indicate when the preamp is in the line. This same LED also indicates when transmit power is being sensed.

The QSA 5 is available from *Janel Laboratories, 3312 S.E. Van Buren Blvd., Corvallis OR 97330.* The unit is available from stock at $39.95 plus postage. A full 1 year warranty is provided.

NEW SIGNETICS LSI CIRCUIT PRODUCES HF AND VHF SIGNAL GENERATION

A frequency synthesizer that uses digital phase locked loop techniques to generate radio frequency signals in the HF and VHF range is now available as a large scale integrated (LSI) circuit from Signetics.

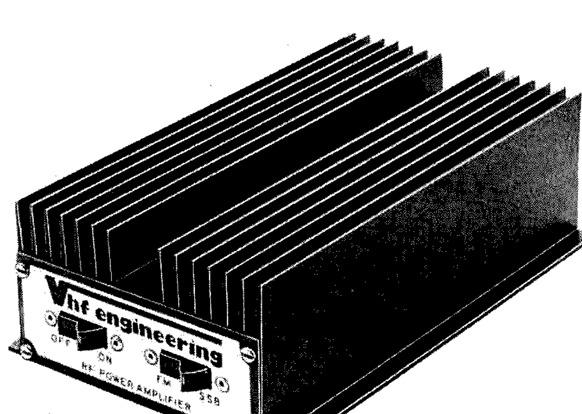
With low power Schottky and emitter coupled logic (ECL) technologies integrated into a single substrate, the new Signetics circuit, designated 8X08, operates at 80 MHz input frequencies with typical system power of 1.6 mW per gate.

As unique design features, the 8X08 incorporates an onboard reference crystal oscillator and an ECL prescaler, according to Dr. John Nemec, Product Planning Manager in Signetics' Logic Division.

Dr. Nemec said the new frequency synthesizer is expected to have major applications in the design of aircraft and marine radio equipment, in instrumentation circuits such as for signal generation in test equipment, as well as in synthesized AM/FM radios.

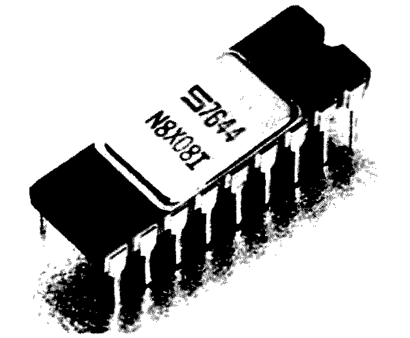
The 8X08 provides the major functional elements of a phase locked loop frequency synthesizer within a single LSI device. A VCO and loop filter are all that are required to complete the synthesizer circuit. The 8X08 contains all other major functional blocks, including a fixed frequency reference oscillator and divider chain, a phase comparator, and a programmable

The Edgecom System 3000 microprocessor-based 2m transceiver.



The new VHF Engineering Blue Line series of VHF/UHF amplifiers.

Heath's new HD-1426 field strength meter.



The Signetics 8X08 Frequency Synthesizer — digital PLL techniques to generate rf in the HF and VHF range.

counter chain for channel selection.

The fixed prescaler for the FM input is a key to the design since it is required in phase locked loops where very high frequencies are to be generated as a means of dividing the local oscillator frequency down to a frequency compatible with the programmable counter, Dr. Nemec said.

In the 8X08, the ECL prescaler is utilized to make possible programmable channel spacing to 100 kHz for FM-receiver local oscillator generation, when using a 3.6 MHz reference oscillator crystal and an external ÷2 circuit. A total of 2000 channels is possible when using the FM input.

Operating features of the circuit include maximum power dissipation of 680 mW and a single 5 V power supply. *Signetics, 811 East Arques Avenue, Sunnyvale CA 94086.*

HEATH HD-1426 FIELD STRENGTH METER

Heath Company, Benton Harbor, Michigan, has introduced a new kit for amateur, CB and marine radio operators. The HD-1426 field strength meter measures the relative field strength of signals from transmitters from 1 to 1000 Watts covering 1.8 MHz to 250 MHz. It can be used to check transmitter operation and to make transmitter and antenna adjustments. The HD-1426 will function with any transmitter having an output from 1 to 1000 Watts.

The HD-1426 incorporates both a built-in printed circuit antenna and a whip antenna as well. It may be used as either a mobile or fixed station device, and is mail order priced at $10.95.

For more information about the HD-1426, send for a free copy of the latest Heathkit catalog. *Heath Company, Dept. 350-23, Benton Harbor MI 49022.*

NEW MOTOROLA HEP CATALOG

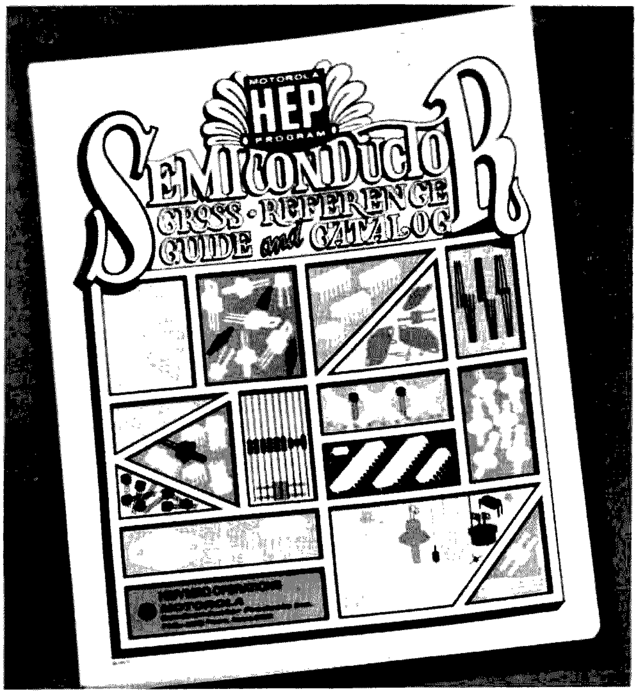
Motorola's HEP semiconductors are offered as replacements for over 60,000 different discrete devices and ICs. Intended for, but not limited to, the hobbyist, experimenter, and the professional service technician/dealer, the HEP products are specified to meet or exceed the important mechanical and electrical characteristics of the replaced device. In many cases, one HEP device will be recommended as the replacement for a large number of components. Because of this one-to-many ratio, the HEP device specifications will often exceed some of the specifications of a number of the replaced devices.

Because Motorola is not responsible for the design of the circuits in which HEP products are installed, and because the HEP device parameters may exceed the original, Motorola Semiconductor Products does not guarantee that the HEP device will perform exactly as the original device. However, the availability of this vast array of potential replacement devices, through a large national network of retail outlets (over 1500), can offer a considerable savings of time or money, or both, to the hobbyist and professional technician alike.

The latest edition of the *Motorola HEP Semiconductor Cross Reference Guide and Catalog* was scheduled for May, 1977. This 184 page book describes discrete silicon and germanium power transistors, thyristors, small-signal FETs and bipolar transistors, CB rf power transistors, zeners, rectifiers, and optoelectronic devices. Digital ICs, in RTL, HTL, DTL, TTL, and CMOS technologies, are also included as well as linear bipolar radio/television ICs, voltage regulators, op amps, etc.

One hundred ninety-eight new products have been added to the *Catalog* — 104 are newly offered TTL functions. Industry popular TO-220 packaged components are also included. A single chip, 3½ digit DVM IC that utilizes CMOS technology to provide both linear and digital circuit functions is also covered. The Catalog also described the Educator II microcomputer and power supply kits.

The unit price of this new *Motorola HEP Semiconductor Cross Reference Guide and Catalog* is $2.00, available from HEP/MRO Operations Headquarters and HEP distributors. *Technical Information Center, Motorola Semiconductor Products, Inc., PO Box 20294, Phoenix AZ 85036.*



GOLD LINE MICROPHONE CLIP

A new microphone clip (the No. 1108) has been introduced by Gold Line Connector of East Norwalk CT. A Gold Line spokesman said that it is sometimes inconvenient, or very undesirable, to drill holes or to rely on a magnet to hold your mobile microphone in position on the dash of your car or truck. The 1108 is backed with a rugged adhesive that gives excellent holding power. It can't vibrate or pull free.

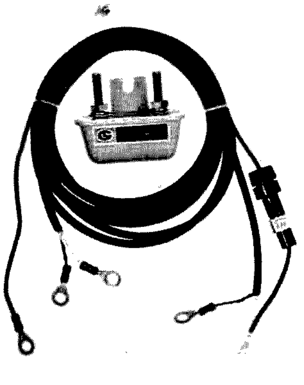
Gold Line designs and produces a complete line of accessories, including noise filters, antenna matchers, coax switches, and wattmeters, to name a few. *Gold Line Connector, Inc., PO Box 893, East Norwalk CT 06855.*

GOLD LINE NOISE FILTERING HOOKUP HARNESS

A new noise filtering hookup harness (the No. 1106) for the two-way communications market has been introduced by Gold Line Connector. A company spokesman commented that noise affecting two-way communications is generated from various sources in your automobile and is picked up by either the radio antenna or the vehicle wiring that supplies power to the communications equipment.

The primary function of the 1106 is to reduce the noise picked up by the wiring. Double barreled filtering action is supplied by heavy-duty coaxial cable for the power pickup which shields against unwanted noise and a ferromagnetic filter that further reduces any remaining interference.

Gold Line designs and produces a complete line of accessories for the two-way communications market, which it sells through a national distributor system. *Gold Line Connector, Inc., PO Box 893, East Norwalk CT 06855.*



The Gold Line noise filtering harness.

RM-2429 RM-2507
RM-2545 RM-2550

In the Matter of

Deregulation of Part 97 of the Commission's Rules regarding emissions authorized in the Amateur Radio Service.

FIRST REPORT AND ORDER

Adopted: March 2, 1977;
Released: March 10, 1977
By the Commission:

1. A Notice of Proposed Rule Making in the above-captioned matter was released April 22, 1976, and published in the Federal Register on April 28, 1976 (41 FR 17789). The deadline for submission of comments by the public was June 23, 1976. Reply comments were due by July 23, 1976. In response to a petition by the American Radio Relay League, the time for filing comments and reply comments was extended to August 4, 1976, and September 3, 1976, respectively.

2. Docket 20777 proposed to revise the amateur rules regarding authorized emissions. Rather than attempt piecemeal reform, the Notice proposed to delete all references to specific emission types and to replace them with limitations on the permissible bandwidth an amateur signal may occupy in the various bands. Additionally, the Notice proposed a purity of emissions standard which would replace the present regulations.

3. A total of 333 persons and 8 clubs filed individual comments. In addition, 23 petitions were filed as comments, adding 625 names. All of these comments are being carefully reviewed. This First Report and Order will address the problem of purity of emissions only. A future Report and Order will deal with the major issue of authorized bandwidths.

4. The present statement of Commission policy regarding emission purity in the Amateur Radio Service is found in Section 97.73 of the Commission's Rules. Section 97.73 states in part that "[s]purious radiation from an amateur station being operated with a carrier frequency below 144 megahertz shall be reduced or eliminated in accordance with good engineering practice . . ." The United States, as a signatory to the International Telecommunications Convention (Geneva, 1959) is bound to the international standards of emission purity. Article 12, Appendix 4 of the Radio Regulations of the I.T.U. requires an attenuation of 40 dB for spurious emissions below 30 MHz, and 60 dB[1] for emissions between 30 MHz and 235 MHz. By this Report and Order, the Commission brings amateur rules into conformity with international standards.

5. Standards for emission purity in the Safety and Special Radio Services are based on the nature of the signal transmitted. The modulation of the transmitted signal produces sidebands needed to carry information to the receiver, plus additional products caused by the modulation and amplification process. It is difficult to suppress completely the undesired emission products without causing unacceptable suppression of the sidebands carrying the information being transmitted. A reasonable degree, however, of suppression of the undesired emissions is needed. This is achieved by a three-step approach. For example, the Land Transportation Services require that for spurious emissions removed from the authorized bandwidth by more than 50 percent but less than 100 percent of the authorized bandwidth, the mean power must be attenuated at least 25 decibels below the mean power (P_m) of the emission. For emissions removed by more than 100 percent but less than 250 percent of the authorized bandwidth, attenuation must be at least 35 decibels below P_m. Beyond 250 percent, attenuation must be either 43 dB + 10 $\log_{10} P_m$ or 80 dB below P_m, whichever is less attenuation. This three-step attenuation is what can most likely be obtained with the usual tuned circuitry of rf amplifiers. Beyond 250 percent is considered a reasonable point to have other additional circuitry which will provide the attenuation we wish for the other spurious and harmonic emissions.

6. The standard proposed for amateur radio in our Notice in Docket 20777 was at least 40 dB for emissions removed from the authorized bandwidth by 250% or more of the authorized bandwidth. In determining a level of emission purity for the amateur service, the 25 dB and 35 dB steps were not proposed since it was intended to have this rule remain simple. The adjacent channels which the first two steps might affect would generally be within the amateur bands and the maintenance of non-interference would be handled on a self-enforcing basis among amateurs. However, beyond 250% there exists an entire range of spurious and harmonic emissions which could create problems outside the amateur bands, and would not be as obvious to the operator until a case of interference occurred.

7. The 40 dB specification was proposed as a first step toward the problem of purity of emission. 40 dB represents an attenuation of spurious and harmonic emissions to a level of 1/10,000 that of the fundamental. This means that for an amateur station which has a 200 Watt output, spurious emissions may be no more than 0.02 Watts. Therefore, 40 dB should provide a degree of protection to operations which would not be affected by interfering signals of 0.02 Watts or less. The effects will vary from location to location, from band to band, and for different emission modes. It is a level of attenuation which the Commission believes can be readily met by most equipment on the market today, and would not require expensive remodeling of equipment by the amateur. It will, however, restrict the use of linear amplifiers which are not meeting what the Commission regards as minimal standards of purity. In a memorandum to the Office of Chief Engineer written November 26, 1976, FCC/OCE LAB Projects 82-025, 82-026, 82-027, 82-028, the Laboratory Division detailed the results of tests of linear amplifiers purportedly sold for use in the Amateur Radio Service which indicate that many such amplifiers achieve harmonic suppression far less than 40 dB, especially in the second and third harmonics.

8. The new rule, as adopted, is a modification of the rule proposed in the Notice of Proposed Rule Making. Because there has been no decision regarding Docket 20777's proposed bandwidth rules, we are unable to enact the rule as proposed. Section 553(a)(3) of the Administrative Procedures Act requires that general notice of a rule contain either the terms of substance of the proposed rule or a description of the subjects and issues involved. Therefore, in keeping with the scope of this rule making, we are adopting the international standards of emission purity which generally relate to the 40 dB level of attenuation proposed by Docket 20777.

9. The International Telecommunications Convention of 1958 requires that all spurious emissions be attenuated by 40 dB when transmitting on frequencies below 30 MHz. When utilizing frequencies between 30 and 235 MHz, transmitters with power output below 25 Watts will be required to attenuate their spurious emissions by 40 dB; transmitters with power output of 25 Watts or more will be required to attenuate their spurious emissions by 60 dB. Amateurs operating near the edges of amateur bands should give due consideration to these attenuation requirements. We consider these international standards to be a minimal level of purity, but to have required higher levels of attenuation would not have been within the scope of this proceeding. The Commission will be instituting a rule making to investigate the need for higher levels of spurious emission attenuation in the Amateur Radio Service. Additionally, upon the disposition of Docket 20777, Section 97.73 will be modified to reflect the docket's final outcome.

10. We received 12 comments specifically addressing the proposed change in emission standards. Of the 12, 2 supported the rule change fully, 2 supported some definite standards, but offered a different standard of emission than the one proposed by the Commission, 5 expressed misgivings over the expense to the amateur and the enforcement of such a standard, and 3 expressly preferred the present standard. Of those who either expressed misgivings or opposed the change entirely, the comments of John V. Durant of Albuquerque, New Mexico, are typical: "From a pure technical standpoint, determination that the emission is at least 40 dB below the peak output power on any frequency removed from the upper and lower limits by more than 250% is a controversial (subject to several interpretations) and a very sophisticated measurement. I do not believe that even 1% of the presently licensed amateur radio operators have the capability or will attempt to acquire the capability to make such a measurement. Further, I doubt that from an enforcement standpoint (presumably FCC monitors) that such a regulation is enforceable." Other comments raised similar issues: the expense of obtaining equipment to monitor the spurious emissions; the resultant lack of adherence to the new rule by the bulk of amateurs; and the difficulty of enforcing the rule.

11. The problem of enforcement mentioned by several comments would be no greater than enforcing any of the standards of Section 97.61 through 97.73. Investigation of interference complaints and normal FCC monitoring will bring the obvious violations to light. However, establishment of a readily measured standard will provide a clearly defined measurement by which to determine compliance. "Good engineering practices," the present standard, has proved to be too indefinite a regulation to enforce effectively. The change, rather than hampering enforcement, should aid it.

12. Finally, we note that two of the comments offering technical criticism of the emission standards as proposed make valid arguments. James E. McShane of Omaha, Nebraska, states, "The proposed section 97.65 and 97.73 bandwidth limitation standards do not take into consideration the range of amateur power usages, from 1/10 of a Watt to the proposed 2.0 kW spread . . . Different regulations should be adopted for low power operation and equipment, or in the alternative, the regulation should be based on a minimum specified power, or actual power, whichever is greater." Gordon Schlesinger of San Diego, California, comments, "I propose that the Commission bring the stated purity standard of 40 decibels of attenuation below peak carrier power more closely into line with the standards existing in the Land Mobile service. A standard of 40 dB + $10\log_{10}$ (peak carrier power, in watts) would establish an absolute standard for attenuation of spurious emissions. Since power delivered to the input terminals of a receiver is proportional to the absolute (not relative) output power level of the transmitter whose emissions are being received, it makes sense to require maximum absolute limits to spurious radiation in the Amateur Service."

13. The above comments are well-taken. As Mr. McShane proposed, we have adopted the ITU regulations with respect to certain low power transmitters. Moreover, the Commission would like to note that the Notice of Proposed Rule Making, Docket 21000, which proposes increased attenuation for spurious emissions in the Personal Radio Services, contains a statement of Commission policy which promises future Notices addressing the matter of harmonic and spurious attenuation for all other services below 1 GHz, including Amateur radio. We would like to reaffirm that statement here and suggest that the above comments are excellent examples of the ideas the Commission will be seeking. Adoption of these present emission standards will not end the Commission's interest in purity of emissions, and we solicit noteworthy comments such as the above in future proceedings.

14. Additionally, the Commission has recently proposed in Docket 21117 type acceptance for commercially marketed amateur equipment. The type acceptance standards proposed would require a 43 + 10 log (mean power in Watts) decibel suppression of spurious emissions, a standard similar to the one suggested above by Mr. Schlesinger. As stated in the Notice of Proposed Rule Making, this degree of attenuation would apply only to amateur equipment which would be commercially marketed. Homemade equipment would be exempt from this standard and therefore adoption of Docket 20777's proposed standards is necessary to bring the entire amateur community into conformity with existing International standards. Until adoption of a Report and Order in Docket 21117, the standards herein specified shall apply to both home constructed and commercially marketed amateur equipment.

15. In view of the foregoing, we are of the opinion that the amended rule as discussed above is in the public interest, convenience, and necessity. Authority for this Amendment is contained in Section 4(i) and 303 of the Communications Act of 1934, as amended.

16. Accordingly, IT IS ORDERED, effective April 15, 1977, that Part 97 of the Commission's Rules IS AMENDED as set out in the attached Appendix. IT IS FURTHER ORDERED that this proceeding IS CONTINUED.

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins
Secretary

APPENDIX

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:

In §97.73, the headnote and text are revised, as follows:

§97.73 *Purity of emissions.*

(a) The mean power of any spurious emission or radiation from any amateur transmitter or external radio frequency power amplifier being operated with a carrier frequency below 30 MHz shall be at least 40 decibels below the mean power of the fundamental without exceeding the power of 50 milliwatts. For equipment of mean power less than 5 Watts, the attenuation shall be at least 30 decibels.

(b) The mean power of any spurious emission or radiation from any amateur transmitter or external radio frequency power amplifier being operated with a carrier frequency above 30 MHz but below 235 MHz shall be at least 60 decibels below the mean power of the fundamental. For transmitters having mean power of 25 Watts or less, the mean power of any spurious radiation supplied to the antenna transmission line shall be at least 40 decibels below the mean power of the fundamental without exceeding the power of 25 microwatts, but, in any event, need not be reduced below the power of 10 microwatts.

(c) Spurious emission or radiation from an amateur transmitter or external radio frequency power amplifier being operated with a carrier frequency above 235 MHz shall be reduced or eliminated in accordance with good engineering practice.

[1] 40 dB for transmitters having mean power of 25 Watts or less.

(d) For the purposes of this section, a spurious emission or radiation is any emission or radiation from a transmitter or any external radio frequency power amplifier which is outside of the authorized Amateur Radio Service frequency band being used.

(e) The above notwithstanding, should any spurious radiation, including chassis or power line radiation, cause harmful interference to the reception of other radio stations, the licensee may be required to take such further steps as may be necessary to eliminate the interference in accordance with good engineering practices.

ENDORSEMENT OF REPORT AND ORDER #20777

The Amateur Radio Manufacturer's Association (ARMA) was formed on January 7, 1977, at a general meeting of all manufacturing interests attending the SAROC Convention in Las Vegas, Nevada. The organization is a self-governing body formed in order to encourage high standards and ethics in the Amateur Radio Industry. The basis and purpose of ARMA is to promote the general growth and welfare of amateur radio and to work toward favorable rule making and legislation for the benefit of the industry, as well as to function as a liaison between the member firms and the Federal Communications Commission (FCC). ARMA is also intended to collect and to disseminate market information to the members.

The membership of ARMA generally applauds Report and Order Number 20777: At long last, we will have some concrete specifications from which to engineer our products rather than merely following good engineering practices.

We are aware of the decision-making power which must go into this rule making, but we have also come to realize that there is a grave oversight on the part of the FCC in one area. This is the subject which we wish to follow up with the FCC, in the form of this petition for a "grandfathering" (grandfather clause) of commercially-built amateur radio transmitter and transceivers manufactured prior to April 15, 1977.

The reasons for this petition are as follows:

1) These products have been built by the legitimate Amateur Radio manufacturers who have not violated good engineering practices or the "spirit" of the law. Should these manufacturers be forced to take back the equipment from inventory of their stocking distributors it would be a significant hardship, possibly to the point of Chapter 11 filings.

2) The distributors and retailers would be faced with horrendous inventories of non-salable used equipment on the shelves.

3) The Amateur Radio Operator as an individual would be adversely affected once again with financial burden when he discovers that his present equipment is no longer legally marketable for outright sale or for trade-in on new equipment that does meet the specifications in Report and Order #20777.

4) The legitimate, self-policing Amateur Radio fraternity and industry would be dealt an injustice brought on by the pseudo-Amateur Radio violating the spirit of the law.

We wish to have the present equipment which does not currently cause harmful interference to other services put under this grandfather clause. And, we feel, this action in addition to the Report and Order #20777 would then strengthen the bond between the Amateur Radio manufacturer and the individual Amateur Radio hobbyist with the FCC.

Last, but not least, we must conclude by saying that this grandfather clause would be a positive move in the public's interest, convenience, and necessity.

In the Matter of

Petition for Rule Making RM-2839 Comments

To: The Commission

ENDORSEMENT OF RM-2839

The Amateur Radio Manufacturer's Association (ARMA) was formed on January 7, 1977, at a general meeting of all manufacturing interests attending the SAROC Convention in Las Vegas, Nevada. The organization is a self-governing body formed in order to encourage high standards and ethics in the Amateur Radio Industry. The basis and purpose of ARMA is to promote the general growth and welfare of amateur radio and to work toward favorable rule making and legislation for the benefit of the industry, as well as to function as a liaison between the member firms and the Federal Communications Commission (FCC). ARMA is also intended to collect and to disseminate market information to the members.

The members of ARMA have studied, with more than a little interest, RM-2839, and find ourselves in agreement with many of the proposals contained therein. We find also, as a representative group, that we have developed a feasible alternative solution to the portion of the ruling involving Type-Acceptance and/or elimination of amplifier equipment in the 24-35 MHz range. We feel that a major change is necessary in this one area.

The organization submits that the legality of licensing retail dealers and/or distributors is not within the jurisdiction of the Federal Communications Commission and, in our opinion, another solution is possible. We propose to the Commission, therefore, this avenue which would enable the FCC to enforce point-of-sale restrictions on *all* parties concerned, whether it be manufacturer or importer, distributor, retailer, consumer, or consumer resaler.

In brief form, for your convenience, we propose that the following data encompasses a viable system:

1) All manufacturers/importers of amateur radio rf generating devices would be required to serial number each and every unit produced and to include a Buyers' Affidavit. The manufacturer would record, in his files, a cross reference of serial number and purchaser data.

2) The Distributor-Wholesaler-Retailer who sells products in the amateur classification would be required to visually inspect a valid Amateur Radio Operator's License (xerox copy acceptable) and to present the buyer with the multi-copy affidavit. The seller would serve as witness to both the transaction and to the actual signing of the affidavit.

3a) The affidavit itself would require the following information: type of product, serial number, call letters of the licensed purchaser, full name and address of the purchaser, and a signed statement of intent that the equipment is for personal use on the frequencies for which the purchaser is so licensed and that he accepts the responsibility for the subsequent use of the equipment upon resale to an individual or group.

3b) Willful violation of any or all of the above stipulations would result in a $1,000.00 penalty fee per occurrence to be levied upon the buyer, dealer, manufacturer, or other party who is responsible in each case.

4) The system would also provide for comparable requirements for mail-order situations. The purchaser would be required to forward the necessary forms and also identification in completed manner prior to the actual delivery of the product.

5) The multi-copy affidavit would be distributed after completion by the purchaser in the following manner: one copy each to the buyer, the dealer, the manufacturer, and the FCC.

We envision this procedure as a more perfectly legal recourse for the FCC to pursue in order to halt the proliferation of illegal CB/pseudo-Amateur products currently on the market. And along these same lines, ARMA feels that the manufacturers should be required to file a separate affidavit supplying the FCC with direct serial number-product description-distribution information.

This alternative proposal, as we see it, offers a path of action with fewer loopholes than the Type-Acceptance route which might well require the elimination of the 24-35 MHz range.

The Amateur Radio Manufacturer's Association remains in total agreement, then, with the FCC's aim to eliminate the illegal use of amplifiers and related equipment. However, we feel that Type-Acceptance in itself is actually an "overkill" and would adversely affect the amateur radio operators as well as the industry itself. Such a limitation would stunt the inventive contributions so often available because of the technical knowledge in the amateur radio world. Our proposed joint effort would form a solid alternative solution which would benefit all parties concerned and would not require more "red tape" or additional enforcement staff at the Federal Communications level.

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington DC 20554
Docket No. 21135

In the matter of

The simplification of the licensing and callsign assignment systems for stations in the Amateur Radio Service.

NOTICE OF PROPOSED RULE MAKING

Adopted: March 2, 1977;
Released: March 11, 1977
By the Commission: Chairman Wiley concurring in the result.

1. In accordance with the Administrative Procedure Act, 5 U.S.C. 553, and Section 1.412 of the Commission's Rules, 47 C.F.R. §1.412, the Commission hereby gives Notice of Proposed Rule Making in the above-captioned matter.

2. During the past two years there has been an unprecedented explosion in interest in personal radio communications in the United States. The popularity of the CB Radio Service has mushroomed to the point where there are now 8.5 million CB licensees, representing an estimated 20 million users of the CB Service. As recently as February, 1975, there were only 1.1 million CB licensees. The Amateur Radio Service has also grown substantially. Although the population of the Amateur Service had remained fundamentally static for several years, the number of licensees has begun to rise, and the number of newcomers to the Service, those obtaining Novice Class operator licenses, has shown particular growth. In December, 1976, for example, there were 36,000 Novice Class licenses outstanding, while in December, 1974, 21,000 operators held Novice Class licenses. The overall population of the Amateur Service is now approximately 293,000. Two years ago it was 255,000.

3. This surge in interest in personal radio commmunications has placed a heavy burden on those members of the Commission's staff engaged in the processing and issuance of licenses for personal radio communications. Although the workload imposed upon the Commission's staff at our Gettysburg, Pennsylvania, license processing facility has increased approximately 1000 per cent over the past two years, the number of permanent staff employees at Gettysburg has increased by only 50%. This has led, in turn, to an increase in the length of time necessary to process and issue Amateur Radio Service and CB Radio Service licenses. Although temporary permit procedures in the Amateur and CB Services allow, in some instances, operation pending issuance of a license, we are very much aware that many amateur radio licensees are dissatisfied with the speed with which their regular licenses are processed and issued, and we are investigating methods by which, assuming no new resources to be forthcoming, service to our amateur licensees might be further improved.

4. The Rules governing the Amateur Radio Service contain licensing and callsign assignment systems of some complexity. At the time these rules were adopted, the size and workload of our Gettysburg staff were such that routine and special amateur application processing could be accomplished without undue delay. As we indicated in the preceding paragraph, however, our resources have not kept pace with the increased demand for personal radio communications. Given these limited resources, we have been forced to assign priorities to our current licensing activities. *We believe our most important task in the Amateur Radio Service to be the processing and issuance of amateur operator and primary station licenses.* We have reached the point at which our lack of resources simply precludes all but the most basic licensing functions. Our regulatory obligations have outstripped our current capabilities. See paragraph 8, *infra*.

5. During most of the boom in personal radio communications, the Commission has been engaged in a program to deregulate the Amateur Radio Service. The proposals and amendments adopted during this period have been intended largely to simplify the licensing and operation of stations in the Amateur Service, and to that extent they complement our desire to improve our procedures in processing and issuing amateur licenses. They have also been intended, at least in part, to reduce the Commission's workload, whenever such a reduction is consistent with the Commission's regulatory obligations. For example, in a Notice of Inquiry and Notice of Proposed Rule Making in Docket 21033, released January 6, 1977 (42 FR 2089), we proposed, *inter alia*, to eliminate from Part 97 of the Rules repeater stations, auxiliary link stations, and control stations. Under the terms of our proposal in Docket 21033, the functions of such stations could be conducted by other amateur radio stations without prior Commission authorization. If adopted, our proposals in that proceeding would afford amateur licensees much greater flexibility in their operations and would also result in a considerable reduction in the workload of the Commission's amateur radio processing staff. Such a workload reduction would, in turn, enable us to redistribute our resources and provide our amateur licensees with better service in other, more vital, areas.

6. We believe the concepts underlying the proposals in Docket 21033 are sound

and may logically be extended to several other aspects of station licensing and operation in the Amateur Radio Service. We are by this Notice proposing revisions of Part 97 of the Rules which, if adopted, would result in a significant simplification of the licensing structure of the Amateur Service and of Part 97 itself.

7. Under the existing amateur radio licensing system, a licensee must obtain both an operator license and a station license. A licensee holds only one operator license and is required by Section 97.40 of the Rules to have, at a minimum, a primary station license, as well. There are several other station licenses available, however, including military recreation, club, special event, Radio Amateur Civil Emergency Service (RACES), and secondary station licenses, and many amateur operators have obtained one or more (occasionally, many more) such licenses. Additionally, many amateur radio operators are eligible for specific station callsigns or callsigns based on particular "preferred" formats.

8. We do not believe that the continuation of the issuance of the various station licenses, other than primary station licenses, listed above or the existence of the current callsign assignment system to be essential to the Amateur Service. The entire system has become extraordinarily burdensome and difficult to administer properly: A disproportionate percentage of our resources must, because of existing rules, be devoted to the processing of special callsign requests and non-primary station license applications. Processing of primary station license applications and operator license applications suffers as a result. For example, as of January 31, 1977, approximately 308,000 stations were licensed in the Amateur Radio Service. Of these, about 95% were primary stations. The other 5% were secondary stations, club stations, military recreation stations, and RACES stations. Yet processing applications for these non-primary stations required resources nearly equal to the resources needed to process primary station license applications. Similarly, Amateur Extra Class licensees comprise only 6% of the amateur population, but processing specific callsign requests from such licensees requires as much (if not more) time as issuing callsigns to the remaining 94%. Clearly, our resources are not allocated in the most effective manner.

9. In this proceeding we are proposing to simplify the basic licensing structure of the Amateur Service by discontinuing the issuance of all amateur station licenses, other than primary station licenses and space station licenses. (Space stations are under consideration in Docket 19852, Notice of Inquiry adopted October 25, 1973, and we are not proposing their deletion.) All amateur radio operators would be limited to one station license. Specifically, we propose to delete from Part 97 of the Rules military recreation stations, club stations, RACES stations (but not RACES itself), and all additional stations, including secondary stations and special event stations. (As we indicated above, we have already proposed in Docket 21033 to eliminate repeater, auxiliary link, and control stations.) Licensees holding the types of station licenses listed above would be permitted to retain them until expiration of the licenses but would not be permitted to renew them.

10. We recognize that the proposals contained in the preceding paragraph would, if adopted, have an impact on certain groups and individuals. We believe, however, that any such impact would be relatively minor and that the Commission and its licensees would realize significant benefits in the long run from the deletion of the station types in question, including the more efficient issuance of operator and primary station licenses. With respect to the specific station types we are proposing to eliminate and the probable effects of their elimination, we would make the following observations:

a. *Repeater stations, auxiliary link stations, and control stations.* Our proposals concerning these stations are fully explained in our Notice of Inquiry and Notice of Proposed Rule Making in Docket 21033, FCC 76-1198, 42 FR 2089 (1977). Basically, the functions now conducted by such stations would be permitted all remaining amateur stations without separate Commission authorization. No one would appear to be adversely affected by adoption of this proposal.

b. *Military recreation stations.* At the end of 1976 there were only 425 licensed military recreation stations, which are amateur stations licensed to the person-in-charge, often a non-amateur, of a land location at which an amateur station has been provided for the use of operators under the auspices of the United States armed forces. We are aware of no need for continuing the separate licensing of such stations. Those amateur operators wishing to operate such stations may do so by operating portable under their own individual station authorizations. We note that one possible disadvantage to portable operation, the requirement that transmissions from stations in portable operation be distinctively identified, was eliminated by the Commission's Report and Order in Docket 20686, 61 F.C.C. 2d 337 (1976).

c. *Club stations.* There are presently 4,500 licensed club stations. Although the elimination of separate club station licenses would have an impact on certain amateur operating programs and traditions, we believe separate licensing of such stations, which may be held by a club comprised of as few as two persons, to be non-essential. Operations now conducted by club stations may be conducted either by club members operating their stations portable or by club members acting as control operators of another club member's station. We are, however, particularly interested in receiving comments concerning the continued usefulness to the amateur community of separately licensing club stations.

d. *Secondary stations.* A secondary station is a separate station licensed to be an individual amateur operator for a location other than the primary station location. Typically, such stations have been licensed for vacation homes or offices. We believe there to be no need to continue to issue authorizations for secondary stations, because, as we noted in paragraph 10(b), *supra*, amateurs may, under the rule amendments adopted in Docket 20686, operate their primary stations at portable and mobile locations without the previous inconvenience of distinctively identifying their transmissions or providing the Commission with advance notification of extended portable or mobile operation. Further, since the suspension of all licensing fees by the Commission, effective January 1, 1977, we have been receiving multiple — and in many instances, frivolous — applications for secondary station licenses from individual amateurs. The applications for secondary station licenses we have received since January 1, 1977, are already beginning to burden our processing staff, and we anticipate a flood of new secondary station license applications as soon as this Notice of Proposed Rule Making is released to the public. For this reason, and to enable the continued efficient processing of other amateur radio license applications, we are hereby declaring, effective with the release of the News Release announcing adoption of this document, a "closed season" on the filing of applications for new secondary stations or special event stations (see below). All applications for new secondary stations received on or after the effective date of the closed season will be returned. Applications for renewal or modification of existing secondary station licenses will continue to be accepted, however. The closed season on filing applications for special event and new secondary station licenses will continue until Commission policy in this area is determined.

e. *Special event stations.* Special event stations are licensed for temporary use in connection with the celebration of an event of either general interest to the public or of particular interest to amateur radio operators, and are intended to bring favorable public attention to the Amateur Radio Service. In 1976 approximately 100 special event stations were licensed. Special event stations are assigned distinctive, unusual callsigns, and it frequently appears that such stations are used not so much to celebrate special events as to enable amateur operation with "exotic" callsigns. We solicit comments concerning the continued usefulness, if any, of special event stations and wish to be provided with specific, concrete examples of special event stations that have brought favorable public attention to the Amateur Radio Service. For reasons outlined above, we are including special event stations in the closed season on the submission of station license applications.

f. *RACES stations.* Radio Amateur Civil Emergency Service stations are stations licensed to civil defense organizations to provide the facilities for amateur radio operators to conduct communications in RACES. Such stations are assigned distinctive callsigns prefixed by the letters "WC". Such stations must in all instances be operated by licensed amateur radio operators, and for this reason we believe such operation can be conducted by amateur operators under their individual station licenses. Functions now conducted by RACES stations and amateur stations participating in RACES would be combined in a form of amateur operation known as "RACES operation." Under this proposal, there would be no change in the basis and purpose of RACES itself, and we believe RACES operations would not be seriously affected if our proposal is ultimately adopted. We do wish to receive comments addressing the utility of separately licensed RACES stations, however.

Deletion of the types of amateur stations listed above would have the added advantage of enabling us to delete the FCC Form 610-B, Application for Amateur Club, Military Recreation, or Radio Amateur Civil Emergency Service Station license.

11. We are also proposing in this proceeding to simplify drastically the system of amateur radio callsign assignment. Under Section 2.302 of the Rules, the Amateur Radio Service is allocated certain blocks of callsigns. Sections 97.51 and 97.53 of the Rules contain rather complex regulations and policies governing amateur radio callsign assignment. Certain licensees are eligible for "1x2" callsigns (callsigns consisting of one letter, one digit, and two letters), others are eligible for certain non-specific "preferred" callsigns, while still others must take the callsigns assigned them by the Commission. We believe there to be no compelling need to continue the complex system of callsign assignment that now exists, a system which, as we indicated heretofore, occupies an inordinate amount of our staff's time, and we are proposing, accordingly, to amend Section 97.51 of the Rules to state simply that amateur radio callsigns will be assigned on a systematic basis. Section 97.53 of the Rules would be deleted entirely. Licensees holding Amateur Extra Class operator licenses would be afforded the opportunity to obtain 1x2 and 2x2 callsigns, but such callsigns would be assigned systematically by the Commission. (Amateur Extra Class licensees would not be permitted, as they are now, to obtain specific 1x2 callsigns of their choice.) Licensees moving from one callsign area to another and modifying their licenses to reflect the moves would not continue to be assigned new callsigns of the same format as the callsigns relinquished. Nor would we continue to issue specific callsigns to former holders thereof. We would not issue any more distinctive callsigns to stations in repeater or RACES operation.[1] Our proposal, if adopted, would result in a much simpler and fairer callsign assignment system and would permit us to concentrate our limited resources in areas more productive for the Amateur Radio Service.

12. The specific rule amendments we are proposing are set forth in the attached Appendix. Authority for these proposals and for the "closed season" announced herein is contained in Sections 4(i), 5(e), and 303 of the Communications Act of 1934, as amended. We invite interested parties to submit comments conerning our proposals on or before June 2, 1977, and reply comments on or before June 30, 1977. An original and five copies of all comments and reply comments shall be furnished the Commission, pursuant to Section 1.419 of the Rules. Respondents wishing each Commissioner to have a personal copy of the comments may submit an additional six copies. Members of the public wishing to express interest in our proposals but unable to provide the required copies may participate informally by submitting one copy of their comments, without regard to form, provided the correct docket number is specified in the heading of the comments. All comments and reply comments filed in this proceeding should be sent to the Secretary, Federal Communications Commission, Washington DC 20554.

13. Individuals wishing to inspect the comments and reply comments filed in this proceeding may do so during regular business hours, 8:00 am to 4:30 pm Monday through Friday, in the Commission's Public Reference Room, 1919 "M" Street, N.W., Washington DC 20554.

FEDERAL COMMUNICATIONS COMMISSION
Vincent J. Mullins
Secretary

APPENDIX

Parts 1 and 97 of Chapter 1 of Title 47 of the Code of Federal Regulations are proposed to be amended, as follows:

§1.922 [Amended]

1. In §1.922, FCC Form 610-B is deleted.

2. In §1.926, paragraph (b)(4) is deleted and designated [Reserved], and paragraph (b)(1) is amended, as follows:

§1.926 *Application for renewal of license.*

(b)(1) Applications for renewal of an amateur operator license, an amateur station license, or a combined amateur operator/station license, shall be filed on FCC Form 610.

(4) [Reserved].

3. §1.951(a) is amended to read as follows:

§1.951 *How applications are distributed.*

(a) Personal Radio Division: Amateur, Disaster, and Personal

4. §1.952 is amended to read, as follows:

§1.952 *How file numbers are assigned.*

(b) File number symbols and service or class of station designators:

Amateur and Disaster Services

Y — Amateur

D — Disaster

5. §1.1115 is amended to read, as follows:

§1.1115 *Schedule of fees for the Safety and Special Radio Services.*

(a) * * *

Amateur Service

Modification of license without renewal ... $3

(b) * * *

(c) * * *

(6) Application for Interim Amateur Permits or Novice Class licenses in the Amateur Radio Service.

6. In §97.3, paragraphs (f), (g), (h), and (i)

---

[1] We are aware that in Docket 21033 we proposed to continue in certain instances to issue distinctive callsigns to stations in repeater operation and that our proposal in this proceeding to eliminate such callsigns entirely is, to that extent, inconsistent.

are deleted, paragraphs (j) through (y), inclusive, are redesignated paragraphs (f) through (u), respectively, and paragraphs (c) and (d) are amended to read, as follows:

§97.3 Definitions

(c) *Amateur radio operator*. A person holding a valid license to operate an amateur radio station issued by the Federal Communications Commission.

(d) *Amateur radio license*. The instrument of authorization issued by the Federal Communications Commission consisting of a station license and an operator license.

Operator license. The instrument of authorization including the class of operator privileges.

Station license. The instrument of authorization for a radio station in the Amateur Radio Service.

Interim Amateur Permit. A temporary operator and station authorization issued to licensees successfully completing Commission supervised examinations for higher class operator licenses.

7. In §97.37, the headnote and text are amended to read, as follows:

§97.37 *Eligibility for station license*.

(a) An amateur radio station license shall be issued only to a licensed amateur radio operator.

(b) An amateur radio station license shall not be issued to a school, club, company, corporation, association, or other organization.

(c) An amateur radio operator shall be issued no more than one amateur radio station license. (This paragraph does not apply to an amateur radio operator applying for a space radio station license.)

§97.39 [Deleted]

8. §97.39 is deleted.

9. §97.40 is deleted and redesignated §97.39, paragraphs (c), (d), and (e) are deleted, and paragraph (b) is amended to read, as follows:

§97.39 *Station license required*.

(b) Every amateur radio operator shall have an amateur radio station license.

10. In §97.41, paragraphs (b), (c), and (d) are deleted, paragraphs (e), (f), and (g) are redesignated paragraphs (b), (c), and (d) respectively, and paragraphs (a) and (b) are amended, as follows:

§97.41 *Application for station license*.

(a) Each application for an amateur radio station license shall be made on FCC Form 610.

(b) If the application is for a station license, only, it shall be submitted to the Federal Communications Commission, Box 1020, Gettysburg, Pennsylvania, 17325.

11. §97.47 is revised to read, as follows:

§97.47 *Renewal and/or modification of amateur station license*.

(a) Application for renewal and/or modification of a station license shall be submitted on FCC Form 610. In every case the application shall be accompanied by the applicant's license or a photocopy thereof. Applications for renewal of unexpired license must be made during the license term and should be filed not later than 90 days prior to the end of the license term. In any case in which the licensee has, in accordance with the provisions of this chapter, made timely and sufficient application for renewal of an unexpired license, no license with reference to any activity of a continuing nature shall expire until such application shall have been finally determined.

(b) If a license is allowed to expire, application for renewal may be made during a period of grace of one year after the expiration date of the license. During this one year period, a license is not valid. A license renewed during this one year period will be dated currently and will not be backdated to the date of expiration.

(c) When the name of a licensee is changed, or when the mailing address is changed (without changing the authorized location of the amateur radio station) a formal application for modification of license is not required. The licensee shall notify the Commission promptly of these changes, however. The notice, which may be in letter form, shall contain the name and address of the licensee as they appear in Commission records, the new name and/or address, as the case may be, and the callsign and class of operator license. The notice shall be sent to the Commission, Gettysburg, Pennsylvania 17325, and a copy shall be maintained with the license of each station until a new license is issued.

12. In §97.51, paragraph (a) is amended, paragraph (b) is redesignated paragraph (d), and new paragraphs (b) and (c) are added, as follows:

§97.51 Assignment of callsigns.

(a) The callsign of an amateur radio station shall be assigned by the Commission on a systematic basis.

(b) An Amateur Extra Class operator may obtain on request, subject to availability, a station callsign consisting of one letter followed by one digit followed by two letters, or a callsign consisting of two letters followed by one digit followed by two letters. Callsigns assigned under this paragraph shall be assigned by the Commission on a systematic basis. No request for a specific callsign or callsign format shall be granted.

(c) No request for a specific callsign or callsign format shall be granted.

(d) * * *

§97.53 [Deleted].

13. §97.53 is deleted.

14. §97.87(b) is amended to read, as follows:

§97.87 Station identification.

(b) If the control operator of a station is not the station licensee, the station identification required by this section shall be the callsign assigned that station. If a station is operated on frequencies authorized by §97.7 for use by the control operator but not authorized for use by the station licensee, the required station identification shall be the callsign of that station followed by the station callsign of the control operator (e.g., WB6XYZ/W6XY).

15. §97.95(a)(1) and (a)(2) are amended to read as follows:

§97.95 *Operation away from the authorized fixed operation station location*.

(a) * * *

(1) When there is no change in the authorized fixed operation station location, an amateur radio station may be operated under its station license anywhere in the United States, its territories or possessions, as a portable or mobile operation, subject to §97.61.

(2) When the authorized permanent station location is changed, formal application (FCC Form 610) must be submitted to the Commission prior to any operation and within 4 months of the move for the purpose of modifying the station license to show the new permanent station location. Operation at the new location is permitted under the license for the former station from the date the modification application is mailed until the applicant is advised of Commission action on that application.

16. §97.103(b)(1) is amended to read as follows:

§97.103 *Station log requirements*.

(b) * * *

(1) The date and time periods the duty control operator for the station was other than the station licensees, and the signature and station callsign of that duty control operator.

17. §97.112(b) is amended, as follows:

§97.112 *No remuneration for use of station*.

(b) Control operators of an amateur station may be compensated when the station is operated primarily for the purpose of conducting amateur radiocommunication to provide telegraphy practice transmissions for persons learning or improving proficiency in the international Morse code, or to disseminate information bulletins consisting solely of subject matter of direct interest to amateur radio operators, provided:

18. §97.163(b) is amended to read, as follows:

§97.163 *Definitions*.

(b) *RACES operation*. Amateur radiocommunication conducted by amateur radio stations in the Radio Amateur Civil Emergency Service.

19. §97.165 is amended to read, as follows:

§97.165 *Applicability of rules*.

In all cases not specifically covered by this Subpart, amateur radio stations engaging in RACES operation shall be governed by the provisions of the rules governing amateur radio stations and operators (Subparts A and E of this Part).

20. §97.169 is amended to read, as follows:

§97.169 *Station license required*.

No station shall engage in RACES operation unless the station is an amateur radio station licensed by the Federal Communications Commission and is certified by a responsible civil defense organization as being registered with that organization.

§97.171 [Deleted]

21. §97.171 is deleted.

§97.173 [Deleted]

22. §97.173 is deleted.

§97.175 [Deleted]

23. §97.175 is deleted.

24. §97.177 is amended to read, as follows:

§97.177 *Operator requirements*.

No person shall be the control operator of an amateur radio station engaging in RACES operation unless that person holds a valid amateur radio operator license issued by the Federal Communications Commission and is certified by a responsible civil defense organization as being registered with that organization.

25. §97.181 is deleted and a new §97.181 added, as follows:

§97.181 *Station identification*.

In addition to the station identification requirements of §97.87, each amateur radio station engaging in RACES operation shall transmit the following additional information: When identifying by radiotelephony, a station in RACES operation shall transmit the word "RACES" at the end of the station callsign. When identifying by radiotelegraphy, a station in RACES operation shall transmit the fraction bar DN followed by the letters "C" or "CD" at the end of the station callsign.

26. §97.185(b) is amended to read, as follows:

§97.185 *Frequencies available*.

(b) In the event of any emergency which necessitates the invoking of the President's War Emergency Powers under the provisions of Section 606 of the Communications Act of 1934, as amended, unless modified or otherwise directed, amateur radio stations engaging in RACES operation will be limited in operation to the following frequencies:

27. §97.189 is amended to read, as follows:

§97.189 *Points of communication*.

Amateur radio stations engaging in RACES operation may be used only to communicate with the following, upon authorization of the responsible civil defense official for the organization in which the amateur radio station is registered:

(a) Amateur radio stations registered with the same or another civil defense organization;

(b) Stations in the Disaster Communications Service;

(c) Stations of the United States government authorized by a responsible agency to exchange communications with stations engaging in RACES operation; and

(d) Any other station in any other service regulated by the Federal Communications Commission, whenever such station is authorized by the Commission to exchange communications with stations engaging in RACES operation.

28. In §97.193, the headnote is revised and the text amended, as follows:

§97.193 *Limitations on the use of stations operating in RACES*.

All messages which are transmitted in connection with drills or tests in RACES shall be clearly identified as such by the use of the words "drill" or "test," as appropriate, in the body of the messages.

WESTERN PENNSYLVANIA REPEATER COUNCIL

In the Matter of

Deregulation of Part 97 of the Commission's Rules to simplify the licensing and operation of complex systems of Amateur Radio stations and modification of repeatar subbands.

Docket No. 21033

Response and Comments

March 17, 1977

by the Western Pennsylvania Repeater Council

The following response and comments to the docket in question are made in cooperation with a committee of members from the Western Pennsylvania Repeater Council. The contents of this response are approved by the total membership of the council (at this time, thirty-eight trustees).

The council agrees with the general intent of Docket No. 21033, but feels that the extent of the deregulation exhibited by this docket is such that it will be abused. We feel that deregulation without structure is not good. The complete relaxation of repeater subbands would create chaos on all bands and make the voluntary jobs of the frequency coordinators or repeater councils one which would be excruciating. We do realize that amateurs have been, by and large, self-regulating, but there is always that one fanatic who goes to extremes when interpreting rules or the lack thereof and will create havoc on the bands. We feel that structured deregulation is necessary.

To be more specific:

Referring to paragraph six of the docket, we feel that there is a definite need to license repeaters separately from those of auxiliary, control, or remotely controlled stations. Deregulation would permit any amateur to put a repeater on the air without prior exhibition of technical competence which your licensing procedure now requires. The other alternative would be to require the amateur wishing to place a repeater on the air to prove his technical competence and receive a frequency from a recognized area council. Furthermore, delete the word repeater from the following statement and have it read: All amateur station licenses would convey authority to operate as control, auxiliary, link, and remotely controlled stations.

Referring to paragraph seven of the docket, we agree with the wording.

Referring to paragraph eight of the docket, we again state that repeaters should be licensed as a separate entity and therefore should be given a distinctive "WR" callsign.

We therefore disagree with the need for the suffix or prefix "R" or "RPT" or the word "REPEATER," but do see the need in auxiliary operation for a descriptive term.

Also referring to paragraph nine of the docket, the council does not care what length of time should be required for station identification. Trustees of repeaters would set their identification interval at any sequence that they deemed sufficient to let the users know what repeater they are working up to the maximum allowable time anyway.

We agree with paragraph ten and would like to make an additional comment. We feel that deregulation could be extended to the point of eliminating the control operator and making the individual amateurs using the repeater responsible for their actions and words while using the repeater.

We also agree with paragraph eleven.

Referring to paragraph twelve of the docket, the council totally disagrees with removal of repeater subbands as stated in a previous paragraph of this response. We further wish to state that repeater subbands should not interfere with other modes of operation within the same frequency band. We feel that there is no place for repeaters below ten meters and that they should be assigned to specific blocks of frequencies only on or above ten meters. We do, however, agree that monitoring of the frequency used for auxiliary operation before and during operation is necessary and in accordance with good operating practice.

Concerning the request for comments

about power limitations, we feel that these limitations should be continued. The basic concept of repeaters was to provide intra-community communications, and a limit on the amount of power accomplishes this perspective. We do suggest a modification of the power limitation rule as it now reads, and that is to reword it to the effect of measuring power at the base of the antenna (at the antenna end of the feedline) and not the theoretical value required by calculating effective radiated power.

Frequency coordinators or area councils (if they handle frequency coordination) must be given additional power to meet anticipated congestion due to the growing number of repeaters. A mandatory requirement of every group or individual wishing to place a repeater on the air should first be to secure a frequency from a coordinator or council. It should be additionally noted that giving the coordinators or councils official power is not a far-fetched idea or just a whim — the Commission refers frequency coordination for the commercial services to an outside firm.

Respectfully submitted,

Daniel H. Rabinovitz K3ISO
Secretary, WPRC

TO:
THE FEDERAL COMMUNICATIONS COMMISSION
Washington DC 20554

COMMENTS OF:
Thomas M. Gooding
206 West Maple Avenue
Sterling VA 22170
Licensee of ARS K4LHB and WR4ABR

IN THE MATTER OF: Docket No. 21033. Notice of Inquiry and Notice of Proposed Rule Making Adopted December 22, 1976.

TITLED: Deregulation of Part 97 of the Commission's rules to simplify the licensing and operation of complex systems of Amateur Radio stations and modification of repeater subbands.

1. The following comments are based on my experience of nearly twenty years as an amateur licensee with emphasis on activity in the VHF region. I am trustee for the Northern Virginia FM Association, Inc., for the repeater license WR4ABR and have served since 1970 as an officer and director of that organization.

2. It would appear that the effort to deregulate the Amateur Service is beginning to exceed prudent restraint. While much deregulation is possible without changing the basic principles and traditions of the Service, caution is necessary to preserve those traditions which have made the Amateur Service and the hobby it regulates so valuable to the public interest. I urge the Commission to take a hard look at the disruption that this and subsequent proposals may cause to the overall service and to consider that some restraint in deregulation is necessary.

3. I agree with the proposal to delete the requirement to separately authorize control, auxiliary link, and other remotely controlled stations, including repeater stations. Since it is no longer necessary to submit to the Commission technical showings to obtain a repeater license, it is only logical to make these types of operation an inherent privilege of a primary or club station license. The addition of "/R" or "/RPT" is quite sufficient to identify this activity.

4. It is still necessary to limit the repeater activity to specific subbands, however. Except for isolated cases, the amateur-administered program of frequency coordination has worked well. This program is based on band plans which are formulated on specific subband assignments for repeaters. The continuous use of a particular frequency by a repeater could give an unfair advantage to the repeater station over non-repeater stations, should all frequencies be available for repeater operation.

5. An expansion of the present allocations is certainly appropriate, however. I do believe that the nature of the VHF repeater vs. the propagation vagaries and lack of traditional channelization makes the MF and HF bands a poor choice to even attempt repeater operation. Therefore, I recommend that repeater operation be limited to frequencies above 29.0 MHz and that present repeater allocations be expanded as follows:

29.0	to	29.7 MHz
*145.0	to	148.0 MHz
221.0	to	224.0 MHz
**420.0	to	431.0 MHz
**437.0	to	450.0 MHz

The expansion of the 146-148 MHz band to the limits above (*) *must* be predicated on the expansion of the privileges of the Technician Class licensee to include the band 144 to 145 MHz. This is vital to preserve the non-repeater operation and non-FM activity now in the frequency band 145 to 146 MHz. This move would consolidate the weak signal activity to just above 144 MHz.

It is also necessary to protect the weak signal and Amateur Television activity in the band 431 to 437 MHz (**). The Commission may also wish to protect the satellite activity in the 10, 2, and 3/4 meter bands.

6. I concur in the proposed deletion of the recording requirement of automatic control (§97.111(g)(2)) and agree that satisfactory rules compliance is practical within the provisions of proposed §97.85(e). However, §97.88(e) should be modified to permit radio control via the repeater receiving frequency as a secondary system to the control facility provided by wire-line or other radio frequencies. This would greatly increase the potential for prompt exercise of the control function from portable and mobile units, particularly when the station is being operated under automatic control. It is important that this uplink control be only secondary and cannot relieve the station of maintaining positive control as now set forth in the rules.

7. After noting it in paragraph 3 of the Docket 21033 Notice, the Commission omitted any further reference to the petitioner's request in RM-2780 to delete the requirement for noting third party traffic in the station log (§97.103(b)(2)). The same reasons that make logging under automatic control unnecessary also make this logging requirement unnecessary. The licensee has the option not to initiate or to terminate third party traffic which is contrary to the regulations.

8. Since only isolated cases of significant problems have occurred in the area of frequency coordination, I urge the Commission to make *no* particular statement on repeater frequency assignment. It might be wise to permit the Commission to officially arbitrate disagreements between individual repeater stations where they can show that they are unable to reconcile their differences in any other way. The proposed §97.63 is probably sufficient if any regulation is needed at all. At no time should the Commission designate non-Commission personnel to administer a frequency allocation program. This is best handled by the ARRL or similar groups of Amateurs.

9. I would endorse the provision in proposed §97.84(c) to permit up to 10 minute intervals between required transmission of repeater station indentifications.

Thomas M. Gooding K4LHB

Ham Help

I am at present preparing for the Extra exam and would like a little information. I am a subscriber to *73 Magazine* and enjoy it very much. Also have the *73 Extra Class License Study Guide*, and *73* 20 wpm tape, all of which I find very helpful. However, do you know of any CW magazine that I can subscribe to? By that I mean any magazine devoted exclusively to CW. I thought I read about one in the March issue of *73*, but am unable to locate the article. Thank you for your kind attention to this inquiry.

Frank Travick
2140 Indian Lake Road
Niles MI 49120

I have two pieces of gear that might be salvaged, but no schematics. One is an HP 524B frequency counter, with a 525A scaler. The basic counter is inoperative. Also, I have a Poly-Comm 62 transceiver for 6 and 2 meters AM. Again, no schematic. I would be willing to reimburse any reader for info on the above units.

I am on Social Security disability, and this is the only way I can get on the air within my budget. Anything you can do would be greatly appreciated.

John P. Dieringer W6RVP
9010 Ramsgate Ave.
W. Los Angelas CA 90045

I am very interested in becoming a ham operator. I started reading your fine magazine 3 months ago in my high school library. I eagerly await each new issue so I can check out last month's magazine and I can study it more closely. I really like your columns, and especially your radio construction projects for beginners. I also think your "Ham Help" column is a terrific public service!

Several of my friends and I want to move up into ham radio, but we are having trouble with the code and desperately need help. We would sure appreciate help from anyone in our area. Also, there are many potential hams besides us, and I think a class in amateur radio would go over very well.

Ronald Carnes
PO Box 285
Leitchfield KY 42754

I would like to hear from hams knowledgeable in the solar power field. I want to build nicad chargers, and twelve volt supplies for ham equipment in field use.

I can help those interested in Zepp, random, and other antennas, as well as transmatches and tuners.

James G. Coote WB6AAM/6
6525 Elder St.
Los Angeles CA 90042

Do you know of anyone in the Nuernberg area of Germany who would be willing to help me prepare for my Novice license? I have been interested for a long time and have made many false starts on my own, but need a person to help me with it to succeed.

SP4 Charles W. Espey Jr.
HHB, 1st AD Arty
APO NY 09070

I reside near the Poughkeepsie area in Dutchess County (NY), and would like to take the Novice test. I would appreciate hearing from any ham willing to monitor the test.

F. Cuillo
Box 145
Wassaic NY 12592

I am eleven years old and deeply into amateur radio. I would like to get into a computerized RTTY system on 24 GHz that will send out a signal in microsecond bursts, but I need a transceiver for that frequency that will handle that situation. Can anyone help?

Jim Woodyatt
6646 Moselle Cir.
Yorba Linda CA 92686

Would like to hear from present owners of the Hallicrafters FPM 200 (not 300) with possibility of forming a club to exchange information of interest.

Jerry Swartzlander W8EPI
PO Box 666
Fremont OH 43420

I am a man 84 years old. I received my Novice license on April 7, 1976, and have had 1 contact so far. I have been off the air for 26 years — had a Technician license for over 20 years, and took sick and while sick my license lapsed. Could you put me in contact with some Novices who need help with the code like I do?

Glenn N. Crawford WB0SLV
207 5th Ave. N.
Humboldt IA 50548

I have a problem I think you can help me with. Over the years, I have picked up a lot of very nice equipment at very reasonable prices. Unfortunately, the I/O code is EBCDIC. Many of the boys are handling this problem with software, but this seems an awful waste of RAM.

There are ROMs available, but the quotes I have received range from $58.00 to $72.50 for single units.

If anyone in your very large readership knows where I can obtain Read Only Memories which convert ASCII to EBCDIC and back for $10.00 or less, would they please let me know?

If I can get my hands on one of these chips, I'll put something together and send you a piece for the I/O section of *73*. There must be a lot of good EBCDIC equipment just gathering dust.

Richard Wright
676 Coe Street
Tiffin OH 44883

P.S. Does this problem remind you of the old 400 cycle power supply problem?

Looking West

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

ANYONE HAVE A SPARE ICEBERG?

A sky so blue it looks as though it were a painting by one of the masters rather than a creation of Mother Nature herself. In the middle of this blue panorama hangs a sun whose white hot rays bring 80° warmth to this scene daily. Nestled below this sky are the mountains, deserts, woodlands and cities that make up the state I call home: California. Only one problem, though. For all her picturesque creativity in building this scene, Mother Nature has gone a bit awry. You see, one would expect to have this scene from mid-June until the beginning of October. However, it's now April, and with little exception the rains we need to grow our crops and provide water to our cities have yet to come.

We are in pretty bad shape out here. At least that's what the TV and the newspapers tell us. Normally our rainy season, approximately mid-October to early June, would bring the water necessary for the rest of the year. However, this year something went wrong, and while most of the nation froze in sub-zero temperatures that were accompanied by heavy snowfalls, out here on the West Coast it was warm and dry. Now the time has come when it looks as if we are going to have to pay the piper for his nice music. Already, a number of Northern California cities have imposed severe restrictions on the amount of water to be used by each person and for each task. Soon I suspect that we here in the Southland will be forced to follow in the same direction. It's a rather heavy price to pay for a warm winter, but it is something that we have no control over. As I said, the time has come when we must pay the price for this winter, unless one of you out there has a spare iceberg or two lying around and wishes to donate same to a worthy cause. Any takers?

When a voluntary coordinating council such as the SCRA administers an area as large as Southern California, it is obvious that the four people who make up the elected directorate along with the members of the two technical committees cannot be everywhere at once. Problems arise, and it would be nice to know when such "brush fires" ignite, so that they can be solved before they reach the "forest fire" stage (as has happened in the past). Then too, when you issue a "90 Day Test Sanction" for a new system, it would be kind of nice to have someone available from the organization to work with those involved, so that they can more easily interface with existing activity. If such is not possible, it would be nice to at least have someone to turn to with a call for help. The evening before the April 2nd SCRA meeting, Jim Hendershot WA6VQP and myself sat in my livingroom pondering just such a problem. It was no secret out here that both Jim and myself were running for elective office within SCRA (Jim for Chairman and I for Vice Chairman), and we wanted to have a few new ideas ready that would enable us to help build even stronger unity within the organization (should it come to pass that one or both of us were elected). The key, we felt, would lie in developing quick lines of intercommunication between us in Los Angeles and the rest of the administrative area. While Jim says it was my idea, I really feel that I must share credit with him for the idea that follows. We call it the "SCRA Area Advisor" – an amateur from each given area recommended to us by his peers who will act as an interface between the people of his area and the SCRA proper. In that way, we felt that any situation that might arise could be handled a lot faster. The fact that such was being dealt with by an area resident rather than a group of "outsiders from the big city" would tend to bring "vibes" of goodwill rather than help fan the flames. We felt that the only proper way to select such people was to let those whom he or she would be working with make the choice, since only in such a way could that person hope to get the support of all amateurs in his or her area.

Both Jim and myself were elected to the offices we were candidates for, along with incumbent Don Root WA6HJW as Secretary and Warren Andreasen WA6JMM as Treasurer. Jim has already opted to reappoint Tom Rutherford W6NUI as 220 MHz Techical Committee Chairman, but as of this moment has yet to pick a leader to handle the same position for two meters. However, we are proud to announce that the first SCRA Area Advisor's position has gone to Paul McClure WA6HGK in San Diego (on the very strong recommendations of that area's representatives present at the meeting). It's only been three days since the meeting, so we are still waiting to hear the recommendations from Santa Barbara, Ventura County, Orange County, the High Desert, and the Low Desert. By next month, we should have the names of those who will be taking on this responsibility for the areas they reside in.

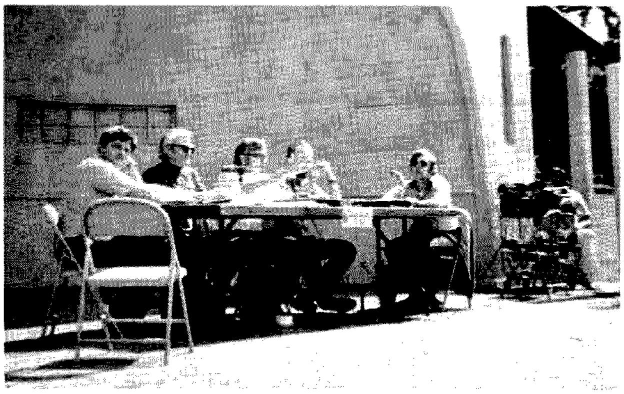
On motions brought from the floor by immediate past Chairman Bob Thornberg WB6JPI, the membership voted to actively seek and implement direct technical committee interface between the SCRA, the Southern California Repeater and Remote Base Association, and the Mexican Coordinating Council, so that each can know what the other is doing and thereby avoid any form of "rf" conflict. The establishment of such an interface only awaits action by these other groups. Fred Deeg K6AEH will be acting as liaison to SCRBBA if all materializes as we hope. A number of people are being considered for the post of Mexican liaison. Again, more on this as it materializes. We also hope to develop direct lines of communication with NARC (the Northern Amateur Relay Council), so that we can work together on any problems common to both organizations. Jim, Don, Warren, and myself have taken on a big responsibility; however, with the help of the technical committees and the overall support of the organization as displayed at the April 2nd meeting, we feel that we can accomplish a lot in building strong repeater and human relations. At least we intend to give it the old "college try."

Special thanks must be given to Bill Carpenter and the JPL Radio Club for the exceptional meeting facilities provided. We met in the Von Karmahn Auditorium at JPL – a place that many of you have viewed on your TV screens during US space missions – and it is, from a technological standpoint, the finest facility that SCRA has access to. There is something special about holding a meeting there, holding a meeting dedicated to the future of amateur relay communication in a place where history was created. A very special feeling of pride.

SUNDAY AND DOCKETS IN THE PARK

21033 . . . 21116 . . . 21117 . . . 21135 . . . RM-2844 . . . RM2839 . . . letters and numbers that hold the future of the amateur service in their collective nomenclature. But, how many hams really know or realize what effect action on any of these will have on his personal amateur career, or on the careers of us collectively. In an effort to educate and motivate interest by area amateurs in just this very thing, a coalition consisting of Alhambra RACES, the Mt. Wilson Repeater Association, and the Amateur Radio Media Workshop sponsored an open format discussion on this topic in Alhambra Park on Sunday, April 3rd. Though hurriedly put together, this meeting was attended by about 70 area amateurs who came to ask questions of such well-known amateurs as Herbert (Pete) Hoover III W6ZH, Bob Thornberg WB6JPI, Lenore Jensen W6NAZ, Al Ogden W6SPK, Don Root WA6HJW, and yours truly. They came because they cared about their own future, and realized that if they were going to air their views on these matters to the Commission, they first had to thoroughly understand exactly what was transpiring in Washington.

They also needed to know what the proper method of filing such responses was, and the intricate why's and wherefore's to include in such responses. They came, they listened to the "experts," they asked questions, and hopefully they went home to file



The panel of experts included (L to R): Don Root WA6HJW, Pete Hoover W6ZH, Chairman Bob Thornberg WB6JPI, Al Ogden W6SPK, and WA6ITF. Not shown: Lenore Jensen W6NAZ. Photo by Chris Williams WB6HGW.

Arriving in style: Pete Hoover W6ZH and XYL with BMW.

Providing audio engineering is the master himself, Bill Orenstein KH6IAF. Photo by Chris Williams WB6HGW.

their own personal views on the pending deregulation and reregulation.

With only two weeks' lead time, it would not have been at all possible to make this a go if it had not been for the efforts of such concerned amateurs as Paul Wirt W6AOP (who procured the meeting site), the ever present and ever available Bill Orenstein KH6IAF (along with his fine Shure Vocal-Master PA system), Orlo Brown K6SUJ (who obtained free use of the dias table and seating), Bob Thornberg (who doubled as event organizer and meeting chairman), and many many others who realized the necessity to both "educate and motivate" amateurs. Although quickly planned, for those in attendance (including a contingent from the SANDRA organization who mobiled up from San Diego, and a duo who flew their Cessna 182 in from up north) it was indeed a success. If they each file a response, it will have been even more of one.

JACK ANDERSON VS. AMATEUR RADIO

Last month I was pretty hard on the ARRL for their failure to act and assume responsibility for the creation of a National Voluntary Band Planning Council. It's now April 5th, and to date I have yet to hear of any positive action in that direction coming from Newington — nor do I expect to hear any in the near future. On this one I hope that I am proven wrong. Come on ARRL, how about surprising us with some positive and quick action on this one!

Now, however, comes an attack upon the ARRL, the FCC and the very structure of the amateur service itself, from none other than the celebrated columnist Jack Anderson. Mr. Anderson writes a widely-read syndicated column for United Feature, 220 East 42nd Street, New York City NY 10067. In this column Mr. Anderson states that in effect it is the amateur service that is holding back the future expansion of the citizens radio service. He goes on to state that from confidential sources and reports, including one prepared for Representative Elliott Levitas of Georgia, he has learned that we amateurs "control" the FCC (ah . . . if only that were true), that the ARRL is a "lobby" for amateur radio (we should only be so lucky), and that we amateurs have "a lock" on the higher frequencies which are interference free (whatever that's supposed to mean). He states that hams control more frequencies than all of the nation's police and fire departments, commercial and educational FM broadcast stations, and TV stations in New York and Los Angeles — *combined!* Well I guess that's true if you count some of the stuff up in the GHz region and light, but tell me, how many QSOs have you had with your flashlight lately, fellow hams? Out here if you stand on your roof calling CQ in CW with a flashlight, the response you get will probably be a police helicopter circling above you with a rather bright light of its own, and a number of police officers on the ground who will want to know why you were up there in the first place and exactly what you were doing.

Anderson claims that FCC Chief Ray Spence has made decisions detrimental to CB. I suppose that if one is in a position of having to enforce the Commission's rules he might be placed in such a position from time to time. However, Mr. Anderson fails to mention that it is the Board of Commissioners, and not Mr. Spence, who makes the decisions around the FCC. In Field Operations, Mr. Spence is only doing his duty to his employer — in this case, the Federal Government in the form of the FCC. Since when is it improper to obey the directives of your superiors, Jack? I'd get fired if I did not follow my bosses' directives!

There is more to this story, but by now it should be clear what the whole thing is about: another attack from CB in the hope of grabbing 220 from us. It was a cruel story, one without any real basis in fact and one that we have heard time and time again. However, I find it a bit hard to hold Mr. Anderson totally responsible, in that I doubt if he has any first-hand experience with either service. I suspect that he thought he had a good story and went ahead with it without bothering to check as carefully into the facts as he should have. Unfortunately for him, this is one that just did not pan out as expected. Even more unfortunately for us, though, this column may well have caused irreparable harm. I sincerely hope that when Mr. Anderson learns the true facts, he will follow up with the kind of story that will punch holes big enough to let all the hot air out of those who would act to discredit the amateur service for the sole purpose of the theft of our spectrum. If anyone can do it, Anderson can. Educate him! The ARRL a lobby for ham radio? We should only be so lucky!

Don't forget to write a letter of education to Jack Anderson. If he gets enough input, and it's the right kind, we just might be able to make a friend of amateur radio out of him — rather than have him as an enemy.

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz. OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz. Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

from page 15

the light of all the extra little unneeded gadgets available on present TV and stereo sets. Why not dispense with them and build a really decent set?

The EIA will also say that government is trying to over-regulate the industry. Well, the rules of free enterprise dictate, and quite rightly so, that if a product is not improved, and needs to be, either the public will mandate it, or the government will regulate it. At this point, the public is not sufficiently aware of the significance of this problem. So, we must rely on regulation to do the job. That is why we need S-864.

I said earlier that S-864 would be a "good start." At this point, this bill does not cover such things as TV/FM antennas and antenna amplifiers, both of which are potential RFI sources, not only to the equipment to which they are attached, but to the equipment of neighbors as well – I should like to see S-864 amended to cover such exigencies.

Wonder Lake IL

NO CB – ITU

Several of your readers seem worried about the proposed 220 MHz Class E proposal. On page 36 of the January issue of *Wireless World*, a British publication, we read, "As far as the international control of radio is concerned . . . Citizens Band radio does not exist. The countries that operate a service are taking advantage of another agreement made in Geneva that countries may use frequencies allocated elsewhere, provided such use has no effect outside their own borders. It was because of this provision that the FCC had to shelve their plans to introduce a Class E service on 220 MHz. Canada and Mexico said it would interfere with their television services."

This might explain why the FCC is now considering the Detroit-backed plan to use 900 MHz for future CB expansion. It would also explain the extreme actions which the FCC has been considering with respect to linear amplifiers.

I was surprised to learn that the British Post Office controls all the radio communications in England. They have *their own* WARC disaster since the Postmaster General doesn't think that he has to reveal any of his proposals for WARC. If anyone expects expansion of amateur radio frequency allocations, then they should ask, who will make the proposals?

I've been working on my code and hope to go for my ticket soon. It would appear that in the future all amateur radio may be limited to the code, since everybody is looking for more frequency allocations, and you amateurs have such a fine tradition for giving. I can see it now – in 2027, the FCC is permitting microprocessor-controlled SSB slow scan audio with an ERP of ½ kW, except during Family Time, which was only temporarily defeated by the major networks in the late 70s, during which time transmissions shall be limited to 4 Watts input power at 27.185 MHz.

Quincy MA

WINTER

Whoever coined the phrase, "when the going gets tough, the tough get going," must have had ham operators in mind.

I would like to bring particular attention to the Cuyahoga Amateur Radio Society (CARS, 146.22/.82), of Cleveland OH. I am sure that this past winter will long be remembered by all, and on 1-28-77, winter dealt its final blow, closing airports, roads, and yes, even whole cities. In their homes, vehicles, and at the Red Cross headquarters in downtown Cleveland, were members of CARS, giving their all in an emergency, throughout the long weekend.

The following were active during the 72 hours that the storm whipped through the Cleveland area: K8TIA, WA8EYF, WB8JSC, W8PSX, WA8GEO, WA8YWN, WD8CHL, K8MBV, K8PPZ, K8AJG, WA8DXY, WD8AJJ, WB8LDA, WA8PIW, and WA8NIL. To all others who assisted in the weather emergency, the entire membership of the Cuyahoga Amateur Radio Society (CARS) would like to extend a heartfelt, "Well Done."

Seven Hills OH

HORSE AND BUGGY

In reply to your request for input regarding use of our HF bands, I would say that I don't have much comment regarding AM because it just seems to have died a natural death anyway. Why forbid horse and buggy rigs after they're gone? There are times when AM is, in my view, justified, even on 20 meters. Take, for example, when a court strips a man of his funds and possessions, and leaves him in deep financial debt and poor health. (Wouldn't such make one at least in mentally poor health?) And don't say that such doesn't happen! I know that it does, from first-hand experience! All after a fellow is too old to make a new start, and too poor in health as well. So if that fellow has some old gear or can scrounge some, AM could be a means of keeping him from going off the deep end, through moping in his troubles. He could get his mind on other matters by yakking with others. Enough of that.

What I would like to propose are a few frequency use changes inside some of our bands. For example, some foreign stations use frequencies above 14.200 for other foreign contacts. The almost universal use of same-frequency transceivers finds many foreign stations above 14.200 in order to work W/Ks (which I don't complain about). But I would much prefer the old method of "split frequency" operation. There seemed to be far fewer pileup situations that way compared to the messes now. I see no way to outlaw transceivers. That is not my thought. My suggestion for a step toward relief is to *ban* US domestic QSOs in certain portions of DX bands, especially when the band is open for DX to at least a portion of the US. Also, because the "foreigns" are allowed in the "US" portion of the bands, why not be reciprocal? Allow W/Ks to use a portion of what is now DX territory for DX contacts only. My example is referenced to 20 meters, but it can apply to 10, 15 or 40m just as well.

Joe Demke W7KCF
Vernonia OR

CA KW

I wanted to tell you about an incident that happened Sunday evening around 4 pm. I have a sick sister in San Diego CA. She is in her middle 30s. I heard a San Diego operator calling someone on schedule. He called for 30 minutes and no contact. This was on 15 meters. I made a quick break-in and asked if he could make a phone call for me in San Diego. He said, "Sorry, old man, I don't have time."

Wayne, I just got my Advanced in November and I do not operate very much, but is this what the amateurs are coming to? This is the type of ham that raises cane when you get 1000 Hertz off his frequency and call CQ. That is what I started to do. I started to wait until he made his schedule, then move 1 kHz and call CQ San Diego. But, I thought, well the ham bands are getting like CB, so I just won't put myself in his class. A typical California kW. By the way, all my folks live in California. When I was there last year when my mother died, I went to visit a ham that had a fantastic antenna setup, but he was too busy to let me see his shack. Probably 6 kW. We sure need some editorials on operating procedures and our responsibilities as hams in emergencies and to our fellow hams. I have been the communications officer for Civil Defense here since 1968 and believe me, it is hard to get enough licensed hams to help. They want the publicity but don't want the work. I bought them all new equipment plus a 2 meter Motorola repeater, Phelps Dodge duplexer, Hal ID, power supplies, you name it. They use the repeater regularly, but where are they when you need them? My CB is more reliable! I now have gone commercial. A complete setup including mobiles and remote base. I intend to get the job done one way or another. I will equip CBers with commercial radios.

I agree this sounds bad, but the hams, of which I am an Advanced class, are bringing it on themselves.

Franklin J. Christian WA4DIU
Johnson City TN

AR VS. CB

Last summer I got a letter from a friend whose husband had just had a heart attack. Because he was temporarily in Calgary, Alberta, her phone number was under another name. It would have taken hours with Ma Bell trying to locate the number.

So I tried amateur radio. A call to the local repeater elicited, "We'll see if anyone has low frequency capabilities." 48 hours later, no phone number.

My own son, 14 and a Novice, was too frightened to originate an emergency message at his minimal 5 wpm. So many kids jumped on him so fast when he first CQ'd that his operating experience had been unpleasant.

So, we joined the local CB club. We are teaching and graduating quality operators into CB, and working road and weather emergencies regularly.

My son and I will be trying for Technical licenses this spring. We won't give up on ham, but it won't be because CB is bad. It will be because we may face our own long distance emergency situation again.

HOT WATER

The following two letters concern the article "An Automatic Thermostat," by George R. Allen W1HCI, which appeared in the January, 1977, issue. After receiving Mr. John P. McDermott's letter, we asked Mr. Allen for a reply. – Ed.

I just read the article on page 62 of the January issue and must say that it is the biggest mess of error-prone nonsense I have ever seen. The author obviously knows nothing about furnace control systems, and you are

nuts to publish the article without having his ideas verified by a competent furnace installer or technician.

To do what he wants you need two items: a second thermostat identical to the first and a twenty-four hour clock switch that can be isolated from the 120 V ac power line. Most of these clock switches can be dissassembled, and the contact wires disconnected from the line cord and reconnected to bridge the outlet socket. Now you have a clock driven switch through which any reasonable voltage can be passed.

Now mount your new thermostat next to the existing one and wire it in parallel, with one exception. Splice the clock operated switch in one leg of the new installation. The new thermostat becomes the day (or high) controller and the existing thermostat is now the night (or low) controller. Set the "on" tripper for days and the "off" tripper for nights. The furnace will always try to satisfy the highest setting it sees.

Now about hot water zone systems. You need a thermostat and clock for each and every zone. Also watch out with hot water systems. Many use line voltage thermostats. It saves the cost of a motor relay. A word now about what happens in a hot water system.

The wall thermostat controls only the circulator pump, and not the burner. When the thermostat calls for heat, the pump is started. This brings colder water into the boiler bottom as the hot water is pushed out the top. This cooling of the boiler controller causes it to close its contacts and fire the burner. This cycling continues until the wall thermostat is happy and the boiler controller is satisfied.

There are three basic hot water zone types. Two are manifold types and the third is a ring loop. (1) Here the water inlets and outlets are manifolded and each zone has its own thermostat and circulator pump. Quite often these are line voltage thermostats. (2) Here we have the manifolds again, but we use solenoid or motor valves for each zone. This requires a three wire thermostat. The extra wire is used to control the pump. There is only one pump on this system, and it must run as long as there is any demand in the system. (3) This system uses a single pump, a single loop of pipe, and a thermostat and valve for every room. The same three wire requirements apply as in (2) above.

Any three wire system should use DPDT switches to remove the unused thermostat from the circuit. This complicates things, as the clock assemblies for this type of system would have to be handmade. But it could be done, and is probably worth the effort.

John P. McDermott
Stratford CT

Mr. McDermott's comments are in error, with the exception of his description of "three basic hot water zone types."

As a reputable author, I take pride in the accuracy of the articles that I submit for publication. All of the articles that I have submitted for publication over the past ten years have been checked in concept by other authorities prior to submission for publication. This article was no exception. In this case, I checked with a local professional engineer who is knowledgeable in heating systems, and a manufacturer of furnace control systems. Furthermore, prior to installation of the unit on my own furnace, I checked with the contractor who installed my furnace during the construction of my home. These three authorities indicated that my ideas were sound and feasible. They did caution me not to attempt to describe every possible heating system and their resultant variations. They advised me to discuss the two common, simple systems discussed in the article in order to keep the article clear and concise. I therefore must take exception to Mr. McDermott's statement that the article is "error-prone nonsense." Instead, the article was verified by competent authorities.

Mr. McDermott states that, "To do what he wants you need two items: a second thermostat identical to the first and a twenty-four hour clock switch. I suggest that Mr. McDermott reread the article one more time, especially the section entitled "Principles of Operation." Mr. McDermott should also take notice of the schematic in Fig. 1 and the parts list at the end of the article. Upon reviewing the article one more time, Mr. McDermott will surely notice that the clock switch is present (Tork 1101 or Sears models) and is isolated from the power line by the 117 V ac relay. The second thermostat is also present and is referred to as the "night thermostat." Mr. McDermott is in error when he states that the second thermostat must be the same as the first thermostat. The second thermostat must be of good quality, such as the thermostat recommended in the article. In some cases the "on-off lag" of the thermostat may have to be adjusted. The instructions that come with the thermostat will describe any such adjustments if they are required.

Mr. McDermott supplies a sketch and description of an alternate connection for the clock switch. Mr. McDermott's connection will only handle a single thermostat. It will not perform the function as described in the article. Mr. McDermott has supplied this sketch since he has stated that ". . . you need a thermostat and clock for each and every zone." This statement is incorrect. For home heating purposes, only a single, centrally located, "nighttime" thermostat is required. As mentioned in the article, temperature uniformity is not maintained throughout the house when the system is in "nighttime" mode. However, as stated, this is of little consequence.

I regret that the article was necessarily limited to "automatic control" of only two simple, generalized, heating systems. However, time does not permit a discussion of all heating systems and their variations. If the experimenter has a heating system that does not conform to the examples in the article and is unable to adapt the automatic thermostat to his system, he can drop me a note and I will attempt to help via letter.

It should be noted that as of this time there are currently four of these systems operational in my neighborhood. (The first systems have just turned three years old.) All four systems have performed well without problems and have given their owners significant savings.

EXTRA CLASS

I'm taking your advice in the preface of the *73 Amateur Extra Class Study Guide* — drop you a letter when the license arrives! Since instant upgrading is in effect, I don't have to wait.

I'd like to thank you and your technical editors for a truly outstanding study guide. I'm a nuclear submarine officer and have been away from amateur radio for about six years. I picked up a copy of your study guide, studied it over a two week period, and that was that. I especially appreciated your practical examples and informative approach. I truly enjoyed reading the guide — as surprising as that may seem to most.

Also, I just took out a subscription to your magazine. I was impressed by the variety of articles in your January issue. I hope the future issues are as good. Keep up the good work.

Ed Giambastiani WB2CTK
Canasota NY

AMP BAN

The FCC released a Notice of Proposed Rule Making, Docket 21116, on 18 February, 1977. This ominous docket would prohibit the manufacture of any amplifier capable of operation between 24-35 MHz. If adopted as a Report and Order, you will no longer be able to purchase an amplifier with 10 meter coverage. Sunspot activity during the next few years will peak, and the loss of this privilege should be of concern to you, no matter what your license class. Comments must be filed on this docket by 25 May.

In an even more disgusting NPRM released on 18 February, docket 21117, the FCC proposes type acceptance for all amateur transmitting equipment. Type acceptance is an expensive, complicated and slow bureaucratic process. It will increase costs of amateur gear! Costs will double, possibly triple, or maybe even quadruple. Small manufacturers will be forced to close their doors, or abandon the ham market. Comments must be filed by 25 May.

Explaining the need for these new rules, which they acknowledge will punish licensed law-abiding amateurs, the Commission cites increasing abuse of amateur transmitting equipment (currently exempted from type acceptance) by CBers and unlicensed

operators who have taken over the frequencies just below 10 meters . . . or in some cases frequencies in the 10 meter band.

In anticipation of these dockets, the San Antonio Repeater Organization filed a petition for rule making with the FCC before their release. Briefly, this petition, assigned Rule Making No. RM-2839, requests that FCC license equipment dealers of non-type accepted equipment and require proof of a valid amateur operator's license for purchase, with appropriate mandatory fines for violations. Nothing in dockets 21116 and 21117 would stop acquisition of amateur transmitting equipment by non-amateurs. It could then be easily modified to cover 11 meters, or used on our amateur bands by unlicensed operators as it now is. FCC is going to do something about the problem. SARO doesn't want to cause serious loss of privilege or inconvenience to any licensed amateur. Certainly we want new rules to effectively end this problem.

The FCC, in the above dockets, asks amateurs to suggest reasonable alternatives. SARO has, yet pressure is obviously needed so that the Petition RM-2839 will receive the consideration it merits.

Bob Wheaton W5PKK
San Antonio TX

PETITION FOR RULES AMENDMENTS

The San Antonio Repeater Organization, a nonprofit society of amateur radio operators, dedicated to the advancement of Amateur Radio Communications and the preservation of this radio service in the public interest, respectfully requests the Commission to amend Part 97 of its rules to provide for adequate restrictions on the sales of transmitting apparatus and rf power amplifying devices currently exempt from regulation under the equipment type acceptance or type approval programs. We further request that the Commission establish a dealer licensing program for dealers engaged in the sale, lease, trade, shipment and distribution of non-type accepted or non-type approved transmitting apparatus at the retail level, and provide for mandatory penalties for any party, who during or after the original retail sale, delivers or causes to be delivered, any such transmitting apparatus to any individual or group of individuals not in possession of a valid license

authorizing its use.

In support whereof, the following is respectfully submitted:

1. The absence of such regulations has been responsible for the proliferation of variable frequency oscillators, linear amplifiers and other transmitting equipment manufactured and sold as intended for the amateur radio market, and thereby protected by the technicality which exempts such equipment from the type acceptance or type approval programs. Much of this equipment is obviously, by its very design, manufactured and sold primarily for unlawful use outside the amateur radio service bands by citizens band or unlicensed operators. The manufacturers' claims that such equipment is intended for the amateur radio market are a subterfuge to permit circumvention of the Commission's Rules, since it is of little or no value for use by the serious radio amateur.

2. Transmitting equipment manufactured and sold by this devious method of rules circumvention is known, by the Commission and others, to be a primary cause of interference to radio and television receivers operated by the general public, and is known to be responsible for significant interference to lawful users of the citizens band radio service, the amateur radio service and other users of the radio spectrum, notably in the public service, marine, aircraft and commercial services. The vast number of persons using the citizens radio service makes it mandatory that they observe closely the 4 Watt transmitter output, as well as other restrictions in Part 95 of the Commission's rules. Harmful interference to other spectrum users caused by lawful operation of citizens band equipment is almost negligible compared to the disruption to legitimate communications caused by illegal citizens band operators, and the new breed of lawless and unlicensed pseudohams, variously described as HFers, whiskey groups, etc., which utilize both unauthorized frequencies in the 26-28 MHz spectrum and transmitter output levels often in excess of one kilowatt.

3. The Commission's ban on CB linears, effective January 23, 1976, is proof that the Commission is both aware and concerned about the harmful effects caused by equipment intended for illegal use by citizens band operators (Part 95) but manufactured and distributed in circumvention of those rules through the false assertion that they are intended for the amateur radio market, and therefore fall under the protective exemption of the type acceptance and type approval programs. While this ban was intended primarily to end future availability of linear amplifiers for use by citizens band operators, it has been effective only in eliminating the VHF (low band) class "C" amplifiers, marketed by reputable manufacturers, which, due to their non-linear amplification characteristics, were of no value in illegal citizens band use. The manufacturers' circumvention of the rules was made possible through technical advances in amplifier design, permitting them to be successfully broadbanded and therefore outside the jurisdiction of the ban.

4. Clearly, the exemption from the type acceptance and type approval programs of transmitting apparatus designed and manufactured solely for use by radio amateurs has made the job of rules enforcement more difficult. However, in spite of recent statements by Commission personnel, that the Commission intends to investigate the possibility of requiring type acceptance for all commercially manufactured transmitting equipment, we submit that the inclusion of amateur equipment into the type acceptance program would fail to get to the heart of the problem. Conversely, a total ban on all forms of linear or rf power amplifiers, an alternative known to be under consideration by the Commission, would be shortsighted and prejudicial to many lawful and conscientious users, and would also fail to stop the availability of high powered transmitters to unlicensed operators. The amateur transceiver offering a power input of two kilowatts PEP, with 11 meter "receive only" provisions, would simply replace the lower powered versions currently available. Clearly, none of the alternatives mentioned so far would effectively control the problems.

5. Simply stated, the problems are primarily the availability and abuse of amateur radio transmitting equipment, by non-amateurs, for unlawful purposes, and the tremendous interference they cause to other radio services' owners of radio and television receiving devices. Much of this interference must be presumed to originate from transmitters operated by the unlicensed pseudoham operators mentioned earlier.

6. A high level of technical competence is necessary for the proper construction and operation of high powered transmitting equipment. Exemption of amateur radio equipment from the type acceptance and type approval program is evidence that the Commission presumes that amateur radio operators will possess the required level of competence, having so demonstrated by successfully completing technical and operational examinations administered by the Commission. Amateurs have done nothing to warrant a change in the Commission's views on this matter. To the contrary, while few of the citizens band or outlaw pseudohams possess more than a rudimentary knowledge of transmitter operation, and have no reserve of knowledge to draw upon in the event of interference to other services, amateurs have demonstrated the highest level of competence and concern in matters of interference and have formed many interference committees to assist when necessary.

7. To eliminate such abuse by persons not licensed to use amateur radio equipment, to stop unlawful encroachment into the amateur bands, and to secure the amateur's future freedom to experiment and develop new communications techniques while providing valuable public service, we recommend that the Commission abandon all other alternatives, in favor of rules changes which would require a valid operator's license for the purchase of any non-type accepted or non-type approved transmitting apparatus. The licensing of dealers engaged in retail trade, in a manner styled after the federal firearms license, as it applies to retail firearms dealers, is certainly indicated. A point of sale registration should be implemented, with appropriate provisions to make it impossible to circumvent the rules through mail order or export sales. The rules change should empower the Commission with jurisdiction in both the original sale, at retail, and subsequent resale by individuals as used equipment. Mandatory penalties for willful violations are recommended. To preclude continued circumvention, such as the inclusion of a disabled transmitter, sold as a receiver only, and type accepted under Part 15 of the rules, any piece of receiving equipment containing additional circuitry not necessary to perform its stated purpose, or kits of parts for home construction of amateur transmitting apparatus, must be presumed to be operational at the time of sale.

8. We respectfully petition for these rules changes, not because the majority of licensed amateur radio operators are guilty of violating their code of ethics, but as the only effective means to control the commercial greed which has promoted such abuses. It is offered as the only reasonable alternative to the Commission's current consideration of more restrictive rules changes in its effort to resolve these dilemmas. We are convinced that such rules changes would cause a minimum of inconvenience to the lawful pursuits of the amateur radio service, and simplify the Commission's enforcement problems to the extent that new personnel would not be necessary to administer a dealer licensing program. We are hopeful that strong regulation of sales will stop the rash of new state and local laws attempting to deal with the radio and television interference problem, most of which are intended as nuisances only, and usurp the Commission's authority to regulate transmission of radio signals.

Wherefore, the premises considered, the Commission is respectfully requested to issue a timely notice of proposed rule making to amend Part 97 of the rules in the manner petitioned.

San Antonio Repeater Organization

MORE BAN

To the FCC:

This Society of 750 licensed amateur radio operators endorses petition for rule making RM-2839, submitted by the San Antonio Repeater Organization. During board action on 19 March 1977, after hearing reports on Dockets 21116, 21117 and petition for rule making RM-2839, directors voted to endorse petition RM-2839.

In support whereof, the following is respectfully submitted:

1. In consideration of rapid advances in the state of the art, and the amateurs' need to adopt and further develop new communications techniques, it is in the Commission's best interests not to impose type acceptance regulations on amateur transmitting equipment to attempt to control unlawful use by non-amateurs, if more effective means are available.

2. RM-2839 proposes more effective means for the Commission to achieve its goal, without imposing unreasonable restrictions on the licensed radio amateur. The simplicity of enforcing regulations proposed in RM-2839 should appeal to the Commission. Substantial savings in budget and manpower would result, permitting more vigorous enforcement in problem areas.

3. Failure to implement restrictions proposed in RM-2839, or adoption of 21116 and 21117 as reports and orders will perpetuate circumvention by failing to interrupt the supply of equipment easily modified for unlawful use by non-amateurs.

Wherefore, the premises considered, the Commission is respectfully requested to consider RM-2839 as a more effective and desirable alternative for the Commission and licensed amateurs.

BROADCASTING

Federal Communications Commission
Washington DC

Comments on RM-2830, Rebroadcast of CB and Amateur Transmissions.

As a radio amateur, I am not opposed to the intent of this petition by the National Association of Broadcasters to provide a more direct channel by which radio amateurs and other services may communicate emergency and safety information to the public at large. I am concerned, however, by what I feel is inadequate assurance that such rebroadcasting privilege would not be abused by competitive, commercial broadcasters and their news departments, nor do I see where adequate provision is made to ensure that such rebroadcasts would be made only with the permission of all participants.

I do not feel that it would be in the best interest of the amateur radio service to have broadcast news people monitoring, and recording, our frequencies in hopes of hearing some interesting, "newsworthy" item which they could interpret as pertaining to "public safety and convenience," to be incorporated into a commercially sponsored news broadcast. Neither would it be appropriate, in my opinion, to air a regular "traffic report" or other such regular program originating through amateur radio. Such uses of amateur radio could be construed as commercial, or

pecuniary, in the competitive broadcasting market.

On my second point, I feel that it should be required that a broadcaster obtain consent of all persons whose radio transmissions were recorded or monitored before such transmissions are rebroadcast, keeping in mind that amateur communication usually involves two or more (often many more) stations. In the situation of broadcast personnel monitoring the amateur radio service for news, is it proposed that the broadcaster have an amateur license so that he can operate an amateur station, break in on the conversation, and ask all the participants for their consent to rebroadcast? Or would such rebroadcast privilege be limited only to such communication as emergency traffic networks, where prior consent of the participants could be obtained?

I feel that the NAB petition fails to set forth adequate guidelines for the broadcast industry that would protect the *amateur radio service from* unauthorized or commercial use, and that action to relax the current protection afforded by the regulations should be deferred until such time that the amateur operators have had an opportunity to review and comment on this important matter.

Washington DC

I have been a licensed radio amateur for over 25 years and have advanced through the ranks from Novice to Extra class. My activities in amateur radio have been of tremendous importance to my vocation. I am Technical Director of a 5 kilowatt directional AM station and a 100 kilowatt FM station with stereo and SCA, and have been recognized as a Senior Broadcast Engineer by the Society of Broadcast Engineers.

I owe much of my success in broadcasting to the opportunities for experimentation and hands-on experience afforded only by amateur radio. One can do very little "experimenting" in the broadcast business; it must be right the first time.

The present state of the art in amateur radio has outmoded the rule allowing only the use of the Baudot code for the transfer of information between amateur stations. Most of the teleprinter machines that use this code are obsolete and repair parts are no longer available from the manufacturer.

The current trend toward the use of microprocessors in amateur radio oriented applications is growing rapidly and appears to be a major step forward. These systems generally use the ASCII 8 level code for information interchange and the use of ASCII on the amateur frequencies would allow greater interchange of experimental information without the necessity for conversion to and from the obsolete Baudot code with the attendant possibility of error.

My position is to support the approval of RM-2771.

St. Louis MO

A MICRO OS

I read with great interest the article published in the March, 1977, issue of *73 Magazine* entitled, "Save Time With A Micro OS." The article was submitted by Mickey and Foxy Ferguson of PO Box 11104, Chattanooga TN.

I have put this OS into my system just as it was published. I have checked and double checked to make certain that I have made no mistakes. I find that the block move, the zero memory, the tape write, and the tape read functions all work fine. I have not been able to list a program. I believe that this is due to my not using a PR-40 (I use a teletype located in the control position). The program was written to print out at 800c. I did change this address to 8004 to no avail. I suspect that the PR-40 being a parallel device is the difference. The dump also stops the program, I suspect for the same reason.

Of more concern to me is that I believe that I have found two places that the program jumps to addresses outside of the program. I do not know where they should jump to, and this is the reason for my letter. I believe that as printed the address at location 035F is incorrect, as it jumps to address 0456. Again at address 03B3, the jump is to address 0467.

Could you please advise me of where these addresses should jump to? I would like to use this program, as I think that there is much to be gained from it. I have already used the block move function to advantage in writing some programs. It is very handy when I forget something — I can move the program down and insert what I have left out.

I would also like to encourage the author to write up another article to tell what he did for the PROM that he is using in his system.

Jack A. Inman
Covina CA

May I begin with an apology to Mr. Inman (and all others fortunate enough to have a hard copy device for their control terminal). I should have included the necessary information in the article on moving the dump and list functions to the control terminal. This is quite easy to do, as only a single change to the OS is required Change the three bytes beginning at $01EA to $7E E1D1. Also, if the device that you have at the control terminal can print sixty-four (or more) characters per line, you may wish to change the byte at address $01AD from $08 to $10, as this will print sixteen bytes per line instead of the eight bytes per line required by the short (40 character) line length of the PR-40. I might add that several improvements have been made to the operating system since the article was submitted to 73 (is any piece of software ever really completed?). If anyone cares to have them, send me an SASE and I will send you a copy of these improvements.

I would also like to add that the dump that was published with the article is correct as published. If you have difficulty in getting any function to run, I would suggest that you recheck the contents of your computer's memory against the memory dump in the article. To answer Mr. Inman's question about the program branching outside itself, it does not. In Mr. Inman's first example (adr. $035E, instruction $26 F6), the $26 is a branch not equal instruction and the $F6 is the offset. In the M6800, this offset byte is a signed number, which can perhaps be summarized as follows: If the most significant bit of the offset byte is a zero, then the branch is forward; if the most significant bit of the offset byte is a one, then the branch is backward. So, instead of branching forward by $F6 bytes to address $0456, it actually branches backward by $0A bytes to address $0356. This (branching backwards) also applies to his other example, which is a $26 B3 and branches backwards to address $0367.

In response to Mr. Inman's question about my PROM board, I must admit that I have been too busy to do it as yet — I'm still using the OS in RAM memory. But several good PROM boards for the SWTPC M6800 computer are available from MSI (Midwest Scientific) and Smoke Signal Broad casting. I would encourage all those who have written and called me about this to check these two sources. — M.F.

10M CB

I have been giving some thought to the idea of using modified CB rigs on 10 meters and I feel that if an across-the-board shift of +2.440 MHz were made, it would provide the perfect "band plan."

Some of the benefits I can see for the amateur service through this type of conversion are — (A) make amateur radio more attractive to prospective hams, now CBers, by providing them with a low cost means of getting on the air after they have passed the amateur exam; (B) encourage more prospective hams and Novices to go for the General class as soon as possible and not stagnate (as I did) as a Technician for years; (C) provide relief for the congestion on 2m FM in major metro areas; (D) provide an alternative to 2m FM for "rag chews"; (E) provide effective inner city mobile communications without high rental repeaters; and (F) protect, by use, the upper reaches of 10 meters.

Ralph E. Delligatti
K3CMY/WB3AUM
17651 Amity Dr.
Gaithersburg MD

The response to CB-10m conversions has been encouraging. We presently have several articles in production describing the process with several different types of CB radios. If anyone has completed a conversion, write it up and submit your work to 73. Don't keep all that originality to yourself! I wonder if anyone has modified one of the CB base or mobile antennas for 10 yet. — Ed.

Ten Meter Band Plan For Converted Citizens Band Transceivers

CB Freq.	Channel #	Amateur Freq.*	Notes
26.965 MHz	1 or A	29.405 MHz	1
26.975	2 or B	29.415	1
26.985	3 or C	29.425	1
27.005	4 or D	29.445	1
27.015	5 or E	29.455	1
27.025	6 or F	29.465	1
27.035	7	29.475	
27.055	8	29.495

Two Meter Scanner

-- for the IC-230

After fighting a continuous battle with crystal manufacturers to get delivery of crystals for the local repeaters, I decided to take the big step and go synthesized. A review of the synthesized rigs available at that time resulted in the purchase of an Icom IC-230 which was on display at a ham radio outlet near a hamfest I was attending.

The rig seemed to have all the features necessary for efficient 2 meter operation: coverage of all standard repeater and simplex frequencies, 10 Watts output, plus or minus 600 kHz transmit capability from receive frequency (the receive frequency is set up on the front panel), and helical resonators for increased receiver selectivity. The latter feature proved invaluable when a new repeater came on in the area and the locals began having intermod problems when it and the other strong local repeater were on at the same time. I found that the IC-230 completely solved my intermod problems. The only problem I had now was that with my previous base setup, I had incorporated a scanner built into the rig to monitor four of the local repeaters plus 52 simplex. When I sold it, I lost my scanning capability, which I sorely missed.

At first the thought of a system that would enable me to scan a synthesized rig seemed like a formidable electronic feat. However, upon closer inspection of this little beauty, it seems that Icom has done most of the work needed.

Brief Operation of the IC-230

The received frequency is converted to the 10.7 first i-f by being heterodyned against the sum of the frequencies generated by the LO and CO oscillators in the phase locked loop section of the rig. For example, when receiving 147.21, the LO frequency is 13.916 MHz, multiplied by 9 internally, or 125.245 MHz, and the CO frequency is 11.265, for a total of 136.51 MHz. The difference between the 147.21 MHz receive frequency and the 136.51 phase locked loop frequency is the i-f frequency of 10.7 MHz. Refer to Fig. 1 for determination of LO and CO frequencies for the receive frequencies desired. The black areas are frequencies available. Fig. 2 is a basic block diagram of the receiver and should give you better insight into the operation of the receiver.

Fortunately, in the phase locked loop section, Icom has thoughtfully provided a switch position ("V" on the 10 kHz switch) which disables the internal CO oscillator and uses it as a buffer for an external VFO. The input to this position is available on a nine pin accessory socket on the right side of the unit. This is meant to be used with a VFO between 11.255 and 12.255 MHz and will cover 146 to 147, or 147 to 148 MHz, depending upon which switch position the MHz switch in the upper left hand corner is in. As a matter of fact, of the connections needed for a successful scanner attachment, i.e., rf injection, ground, plus 12 volts, ptt line access, and squelch access, only the squelch access is not already available at the accessory socket. This, however, is quickly remedied by a 10 minute modification to the transceiver which requires no defacing of the unit and is completely reversible in even less time. This will be described shortly.

Armed with the knowledge of how the unit works and what points are available, it seemed the easiest approach was to build an external oscillator which injected the proper frequency into the CO buffer to enable monitoring of the frequencies of my

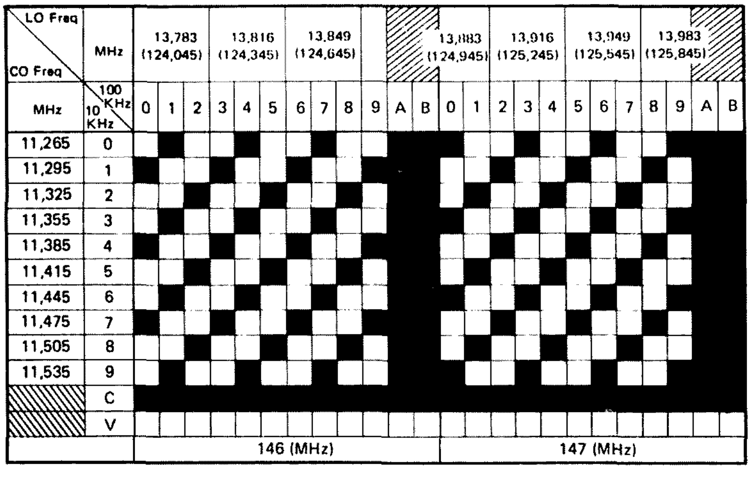

Fig. 1. LO and CO frequencies for receive frequencies desired.

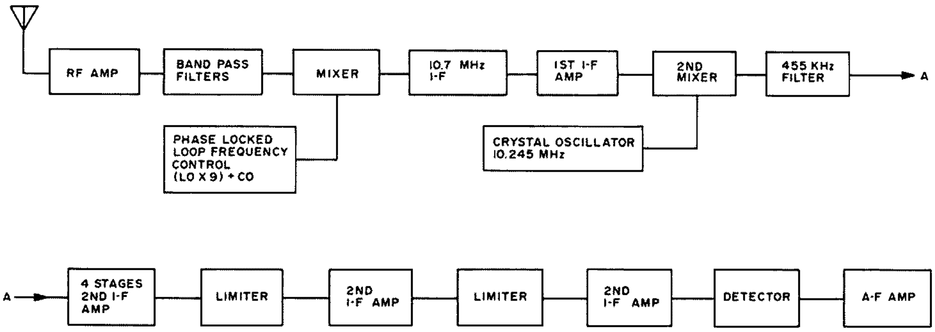

Fig. 2. Receiver block diagram.

choice. With the MHz switch in the "146" position and the 100 kHz switch in the "9" position or, alternately, the MHz in the "147" position and the 100 kHz switch in the "1" position, the LO frequency selected is 13,849 x 9 or 124.945 MHz. To determine the CO injection frequency needed: F = frequency to be monitored minus 124.945 minus 10.7. For example, crystal needed to monitor 146.94 would be 146.94 minus 124.945 minus 10.7, or 11.295. Using one of these switch positions enables you to monitor 146.5 to 147.5 MHz covering simplex and repeater outputs. Using the above formula, the crystal frequency for 146.52 works out to be 10.875 MHz, which is below the 11.255 range for external CO input specified by Icom. However, both IC-230s I own operate very well at 52 anyway.

An added advantage is the capability to scan transmit and receive with a single crystal. There is one thing to watch: When the scanner stops on a particular position, you must notice whether it is a 146 MHz repeater, a 147 MHz repeater, or a simplex frequency, and move the offset switch (located on top of the unit) accordingly or the toggle switch to "direct" for simplex. Transmit and receive scan capability is possible with a single crystal because the CO and LO oscillators are common to the transmitter and receiver.

IC-230 Modification Steps

1. Remove bottom cover of IC-230.

2. Locate two small coaxial cable center conductors connected to pin 9 of the accessory socket, unsolder from pin 9, solder together, and tape. This removes a "CO output" point from the accessory socket.

3. Run a wire from pin 9 of the accessory socket to pin 14 of U4E, the AF board. The AF board is the third compartment from the rear. With the rear of the set facing you, pin 13 can be located just to the left of center and is the only pin on the board without a wire connected to it. It is the squelch test point and will be used to obtain the signal which stops the scanner.

The scanner can be built on a piece of vectorboard and parts layout is not critical, but keep in mind good building practices, including keeping all leads as short as possible. Fig. 3 shows the scanner schematic.

Circuit Description

IC1, a 7414 TTL IC, is a hex Schmitt trigger. Since the squelch voltage of the IC-230 rises and falls relatively slowly, a Schmitt trigger is needed to process that signal to provide an output with a sharp rise and fall time for positive starting and stopping of the scanner. Q11, in conjunction with R1 and C1, provides a time delay to hold the scanner on frequency for a short while after the carrier drops. With the values shown, the delay is approximately 5 seconds. The time delay can be increased by increasing the value of C1 or decreased by decreasing C1.

IC2 is connected as a clock which provides the pulses that tell the scanner how fast to scan. Scan rate can be increased by decreasing the value of C2 or decreased by increasing its value. A word of caution: Increasing clock speed too fast will result in the IC-230 not being able to "lock on" to the externally generated frequency and only sporadic scanning of some channels will be realized.

IC3 is a decade counter which counts the input pulses and presents them in binary form at pins 8, 9, 11, and 12.

IC4 is a BCD to decimal decoder which takes the BCD output of IC3 and converts it to decimal form, bringing the lines connected to pins 1, 2, 3, 4, 5, 6, 7, 9, 10, and 11 to ground one at a time, lighting each LED in sequence and, at the same time, turning on Q1 through Q10.

When Q1 through Q10 turn on, they activate one at a time Y1 through Y10, which generate, in conjunction with Q12, the frequencies needed by the IC-230.

IC5 is a simple regulator which supplies the IC circuitry with 5 volts from a 12 volt source.

If 10 channel operation is not desired, 2, 4, or 8 channel operation can be had by ungrounding pins 2 and 3 of

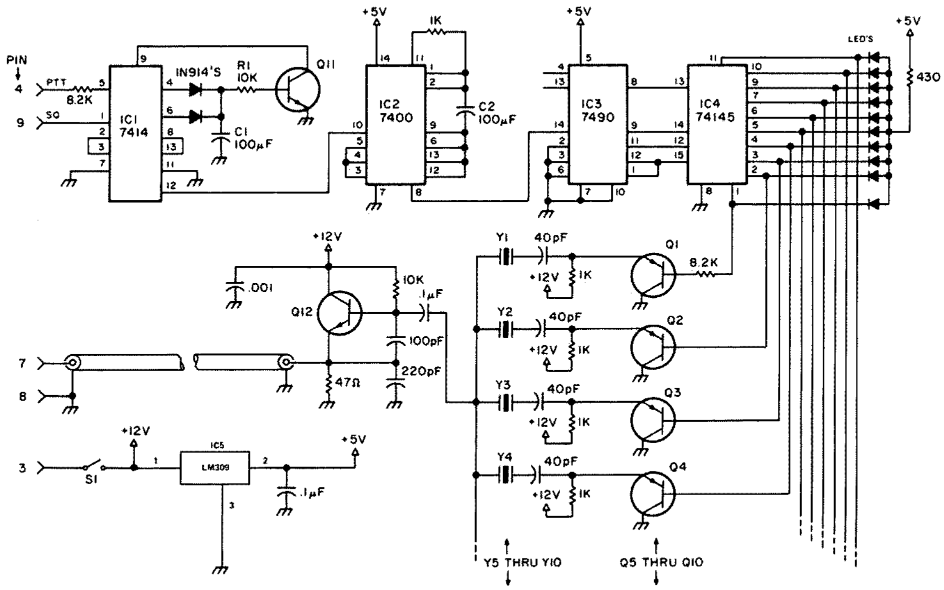

Fig. 3. Schematic. Q1-Q10 — 2N3638 or equiv.; Q11 — 2N2102 or equiv. (any NPN silicon); Q12 — 2N2102 or equiv.; Q13 — 2N3055 or equiv.

IC3 and tying them to pins 9, 8, or 11, respectively. Five channel operation can be accomplished by tying together pins 1 and 6, 2 and 7, 3 and 9, 4 and 10, and 5 and 11 of IC4. Of course, you would only use the amount of transistors and associated circuitry needed to scan the desired number of channels. For example, if only 5 channels are required, omit Q6 through Q10 and components connected to their base and emitters.

Operation

Set "MHz" switch to "146", the 100 kHz switch to the "9" position, the 10 kHz switch in the "V" position or, alternately, the MHz switch in "147", 100 kHz switch in "1", and 10 kHz switch in "V". You will note that the meter light is out, indicating that the IC-230 is not getting a CO oscillator frequency.

Turn on S1; the scanner should now scan and the meter light will be on. If a channel is active, the scanner will stop on that channel. It will begin scanning again after a five second delay when the repeater goes off. If you wish to transmit on a frequency on which the scanner has stopped, simply check to be sure the A-B switch is in the proper position for the repeater you are listening to, or the on-off switch is in "dir" for simplex operation. Simply key the mike button to communicate on that frequency. As stated before, transmit and receive frequencies are scanned simultaneously using one crystal.

Crystal Ordering Information

This circuit will work well with International Crystal Manufacturing Co. catalog #031300 crystal or equivalent. Price is $4.25. The only possible disadvantage might be the physical size. These crystals are the HC6/U type and not the type you normally find in 2 meter equipment. ■

Try the Mini-Timer

-- prevents HT timeouts

Steve Kraman, M.D. WA2UMY
629 Cortelyou Road
Brooklyn NY 11218

The necessity for a timer on repeaters to limit the length of individual transmissions has generated several circuits that the individual ham can use to avoid timing out. None of those that I have seen, however, were appropriate for my purpose, which was to limit my monologues from the car with my Midland hand-held. I wanted a "time out" circuit that would fit entirely in the HT, draw little current, give a loud warning, and not otherwise affect the operation of the rig. The circuit in Fig. 1 fits all these criteria and in addition is cheap and easy to build.

Circuit Description

IC1 is an NE-555 connected as a timer. C1 and R1 determine the timing length. With the components pictured, the timing cycle is about 90 seconds. A small trimpot would give considerable variation above and below this. With pins 2 and 4 connected together and at ground potential through the 10,000 Ohm resistor, the timer is inhibited. Point A is connected to any part of the T-R switch that goes from neutral or ground potential on receive to 12 volts on transmit. When this happens, the timing cycle begins and, unless reset, will eventually go on to time out, causing pin 3 to go to ground. This in turn activates IC2, which is connected as an astable oscillator at about 1000 Hz. Its output drives the transceiver's internal speaker directly through a capacitor. The output is loud enough to be easily heard within a room or car. The tone will sound until the mike button is released and then it resets.

The circuit draws 7 mils on standby and 50 mils when sounding off. I found that I could eliminate all current draw on receive by connecting the points C and A together, therefore only supplying voltage to the unit on transceive. However, when this was done, the oscillator would occasionally go off when the mike button was pressed. Some fiddling with the circuit would probably correct this if the 7 mil draw is unacceptable.

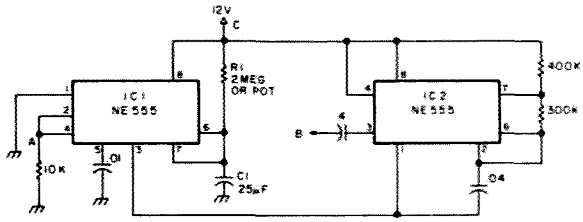

Fig. 1. The Mini-Timer.

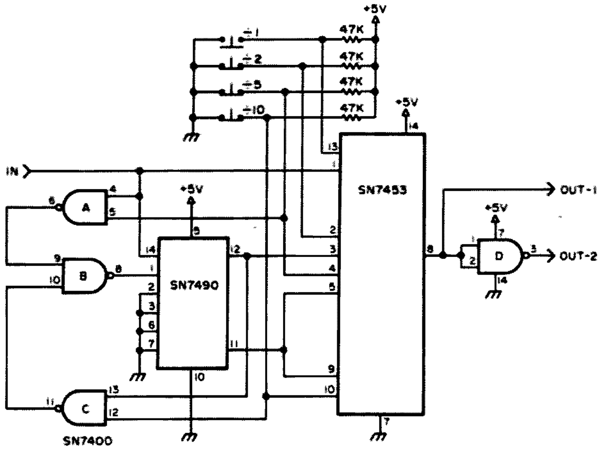
Two additional points: The unit will sound for about ½ second when the set is turned on, confirming the operation of the timer. I have also noticed that when my batteries begin to run down, the timer begins to emit chirping sounds on receive. I find this a convenient signal to recharge.

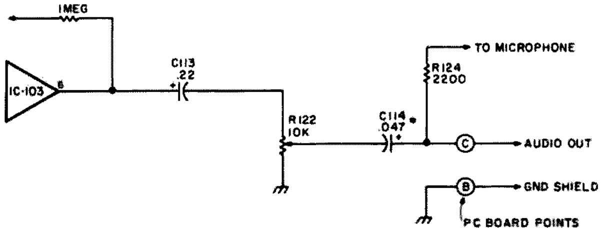
Any construction method will do and none of the component values are critical except the voltage tolerance of the caps. An NE-556 (double 555) cannot be used since both ICs share a common ground and this obviously won't work in this circuit. ■

Circuits²

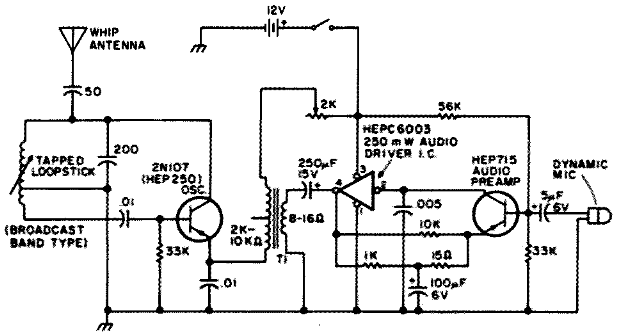
Want a free copy of any 73 publication? Sure you do. Just send in your favorite circuit, or even one that you don't especially like. If we print it, you take home the book of your choice. Just be sure to specify which book you want. OK?



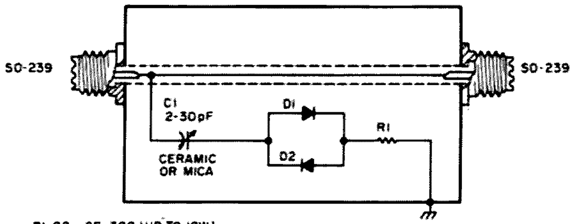
This circuit permits an input square wave to be divided by one, two, five, or ten, depending on which switch is in the open position. The signal at "OUT-1" will be inverted and the signal at "OUT-2" will be non-inverted with respect to the input. Thanks to Eric Grabowski WA8HEB.



Here's a way to match the Heath HD-1982 Micoder to low impedance transceivers. To get around the Hi-Z condenser mike supplied with the Micoder, substitute a 15k ¼ Watt resistor for C114 (.047 uF) capacitor in the audio output circuit. This mod has worked with the Midland 13-505 and Wilson 1402 SM HT. You may have to experiment with different values to find the right match for your transceiver. Thanks to W8FX.



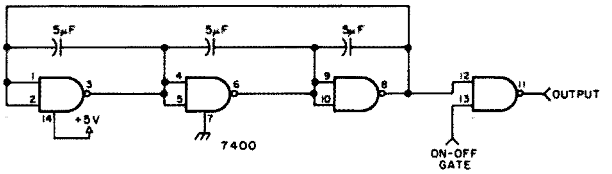
Here's a 1-2 MHz broadcaster transmitter. T1 is a low impedance output transformer, 5000-8 Ohms. Thanks to WA5RON.



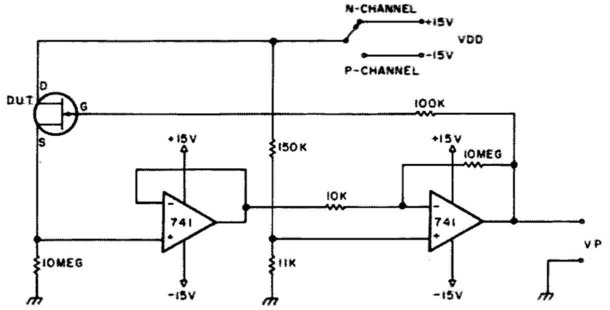
D1, D2 - GE-300 (UP TO 10W)
GE-511 (OVER 10W)

R1 - 50 OHMS OF NON-INDUCTIVE RESISTANCE (5) 250 OHM 2W 5% TOLERANCE CARBON RESISTORS (10W TOTAL)

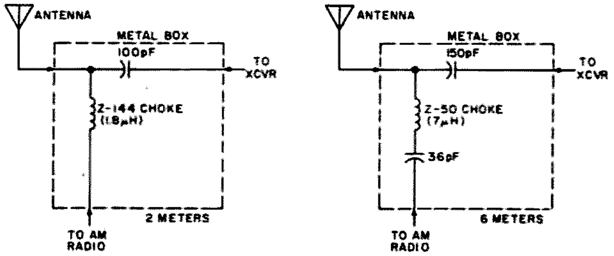
An attenuator useful on all of the amateur bands, but designed with 2m in mind. Capacitor C1 couples the appropriate amount of rf to switching diodes D1 and D2. D1 and D2 conduct only on transmit and pass the rf on to resistor R1. The attenuator is constructed in a minibox sized 3-1/4 by 2-1/8 by 1-1/8. Note that C1 can be mounted using a stiff piece of wire or a terminal strip. All leads should be kept at minimum length. Rf is present on both sides of C1 and must be insulated from the chassis. A small hole can be drilled in the box so C1 can be adjusted using an insulated shaft alignment tool. Thanks to Donald Bohm WB0FLG.



An audio oscillator from a 7400 TTL chip. The output waveform is a sawtooth and will drive other TTL devices. With the values shown, the frequency will be about 800 to 1000 Hz. Thanks to K7HKL.



A very simple circuit for measuring JFET pinch-off voltage. It's particularly handy when trying to match field effect transistors of the same generic type. The circuit also makes it easy to measure the bias range of an FET. The op amps sense the source current of the FET via the first 10 meg resistor. The first 741 is a buffer; the second 741 is preset to 1 volt and its output drives the device under test (DUT) until the source current equals 100 uA. This voltage then can be easily measured with a VOM or VTVM. All resistors are 5%, ¼ W. The polarity for Vp will be opposite with respect to VDD, which is correct since Vp is the reverse bias cutoff voltage. The cutoff current is set for approximately 100 uA. Thanks to Gerry Gannon, Phoenix AZ.



If you're thinking about a disguised antenna system to ward off the Hamburglar, this pair of circuits may be for you. Thanks to K0HZI.

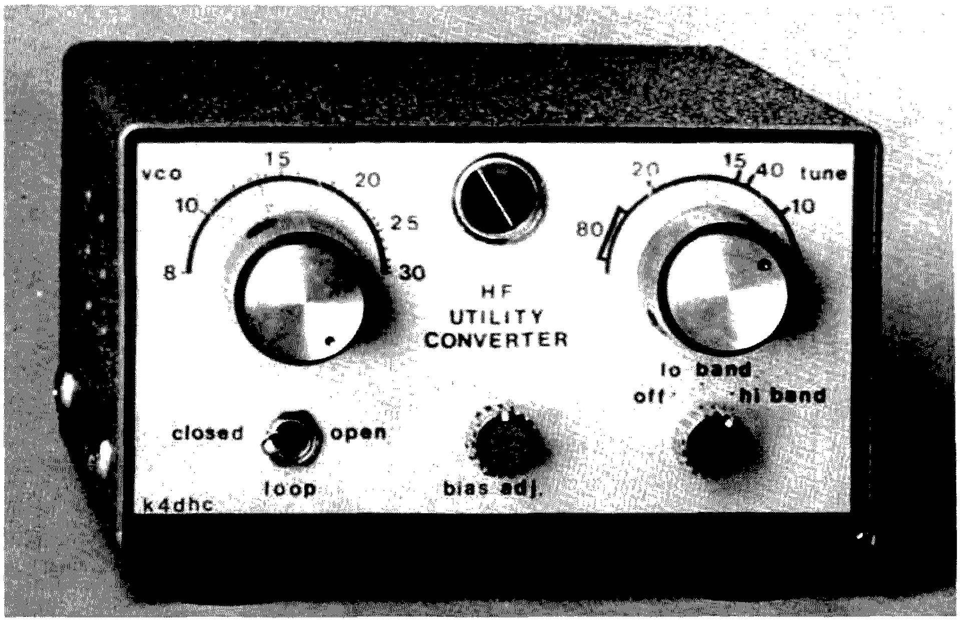
Deerfield Beach FL 33441

High Frequency Utility Converter

- - handy test rig for any shack



The completed converter mounted in its cabinet.

The simple little HF converter to be described here was constructed out of desperation as well as components normally associated with such things. The utter frustration of not having a converter available to check a new i-f system or the wrong crystal for the right band finally drove me to the brink of a bottomless pit over which, but for the solution shown here, I should have perished.

I did a lot of searching through my collection of magazines to as far back as 1964 to come up with a combination of circuits I thought would solve my problem. The result is a circuit requiring but one crystal and no complicated band switching. It will tune to any frequency from 3.0 to 30.0 MHz and convert it to almost any i-f frequency while employing just three transistors and one IC. You can't beat that with a stick.

Basically, the converter is nothing more than a dual gate MOSFET mixer with a tuned input circuit on gate 1 and a stable conversion oscillator signal on gate 2. The tuned circuit is a multiband tuner which covers the 3.0 to 30.0 MHz range without switching.[1,2] The oscillator portion employs a VCO which is tuned over the range of 8.0 to 30.0 MHz and can be phase locked to a 1 MHz crystal for stability and accuracy. Several articles on phase locked local oscillators have been published and all I had to do was take my pick.[3,4] Of the two I studied, the latter by Kenneth Robbins W1KNI was

more up-to-date and required fewer parts. I simplified it even more by eliminating some sections not absolutely necessary for a piece of gear that was to be used primarily for testing purposes.

Converter Circuitry

Fig. 1 is the schematic for the converter. Two of the gates contained in an SN7400N TTL IC are used as a crystal oscillator. The remaining 2 gates are used as buffers and are fed in cascade by the crystal oscillator output. Pulses from these last 2 stages are coupled into a pair of detector diodes, D1 and D2, which at the same time are modulated by output from the VCO. The signal from the detector is amplified and filtered by Q1 and associated circuitry to produce a control voltage for tuning diode D3.

In the original article, an agc circuit was included in the VCO section to maintain constant output. I found the oscillator was quite flat over the range I was operating, so the extra leveling circuits were eliminated. An IC buffer between the VCO and the detector and another between the VCO and external circuits were likewise omitted.

As in the original circuit, an adjustable bias is applied to Q1 to keep the collector at the desired operating point of 6 volts. This occurs when .5 mA flows in the collector load resistor. A 1 mA meter was used in the original article as an indicator for setting the bias. I substituted a battery status indicator with a 200 uA movement and shunted it to read 1 mA full scale. A place is provided on the PC board for mounting a shunt if you follow a similar plan. An audio output monitoring point is also available on the PC board if audio monitoring of phase lock is to be used, as was done in the original article. I found it adequate to use the meter for indicating lock.

The mixer is mounted on the same board with the PLL circuits and makes use of a type 40673 transistor. The multiband tuner assembly is mounted separately, as is the tuning capacitor for the VCO. Output from the mixer is untuned with an rfc forming the drain load element.

Construction

The majority of components are mounted on a PC board 2 inches wide and 3.8 inches long. The 2 variable capacitors, the bias pot, the meter, the antenna transfer switch, and the loop interrupt switch are all panel-mounted. The PC layout and artwork for the board I used are shown in Fig. 2.

The variable capacitors for the VCO and the tuner were identical. They had been liberated from transistor radios and were of the solid dielectric type. Each had 4 gangs with 2 sections of 130 pF and 2 sections of 20 pF each. I used the 2 large gangs for the multiband tuner and tied all four sections in parallel for the VCO. Most of the variables of this type do not have gangs of equal capacitance, so you may have to do a little experimenting with whatever you come up with in order to cover the range you want. The VCO is dependent solely on total capacity to determine its operating range, so look for units with plenty of capacity if you wish to cover a wide range. If you are forced to use a capacitor with unequal sections or values different than those used here for the tuner, some pruning of inductors will be necessary to cover the desired range. The low band inductor can be installed first across the larger of the 2 gangs and the response checked to see if it will resonate at the lowest frequency you require. If not, either add or subtract turns until it hits on frequency and then do the same for the high band coil. If either of the tuning capacitors you are using has integral trimmers, set them all to minimum and leave them there.

L1	15 turns #26 on T37-6 toroid. Tap 3 turns from cold end.
L2	36 turns #28 on T37-6 toroid. 2 turn link over center of main winding.
L3	35 turns #30 on T44-2 toroid. 2 turn link over center of main winding.

Table 1.

Total operating range of the VCO will naturally depend on the value of variable capacitor used for tuning. Mine had a total capacity of about 300 pF at full mesh and less than 10 pF at minimum. The operating range was approximately 8.0 to 30.0 MHz. This can be altered as desired by varying the value of LI, the size of the tuning capacitor, or both. Since I used this converter for bands above 80 meters and fed it into a tunable i-f of 3.5 to 4.0 MHz, the above-mentioned range was quite suitable.

It should be pointed out that standard air variables could be used for tuning if space is not a problem. In any case, some sort of vernier drive will be needed, especially for the VCO. In order to connect a drive to the capacitors, some sort of shaft extension is needed. I accomplished this with a 4-40 headless set screw 3/8" long and a 1/4" round fiber spacer with a center hole threaded for a 4-40 screw. A 4-40 tap was run into the existing hole in the capacitor rotor shaft far enough to take about a third of the set screw. The spacer was then threaded onto the

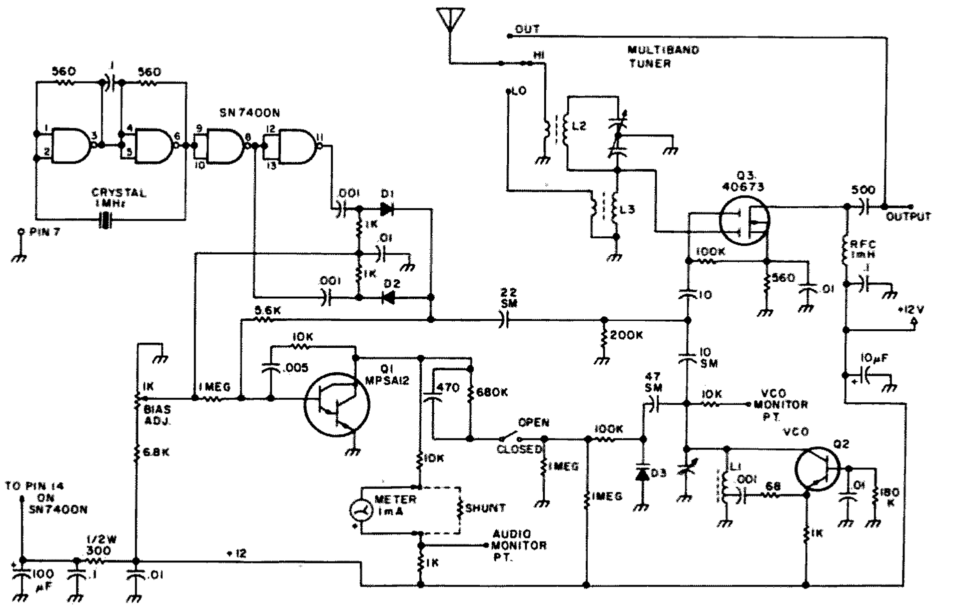


Fig. 1. Schematic for the converter.

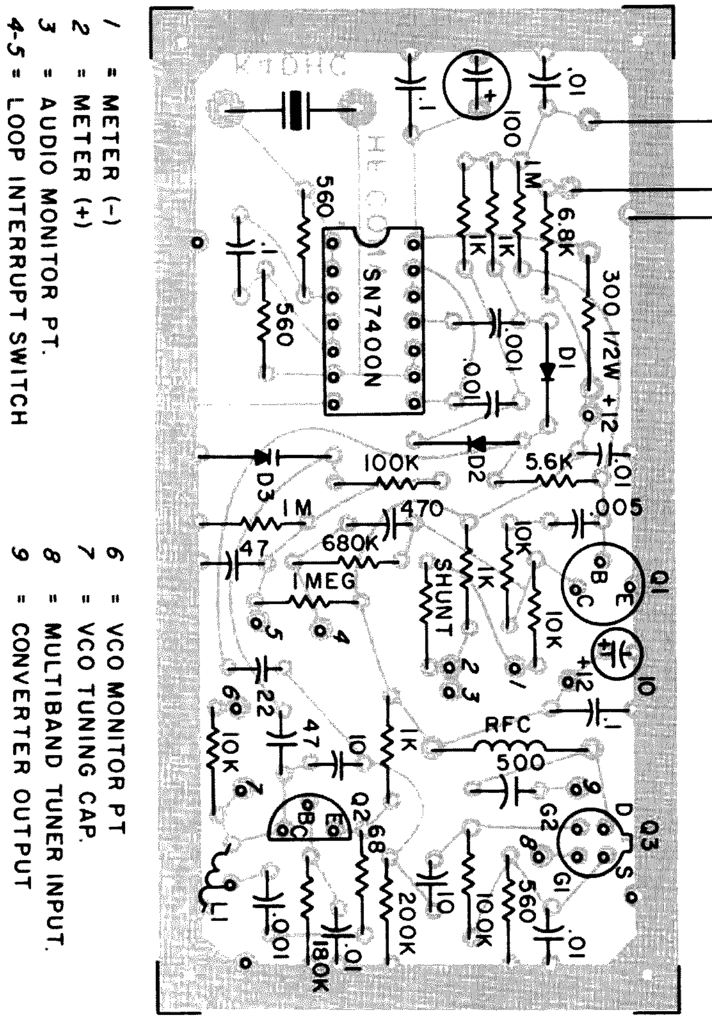

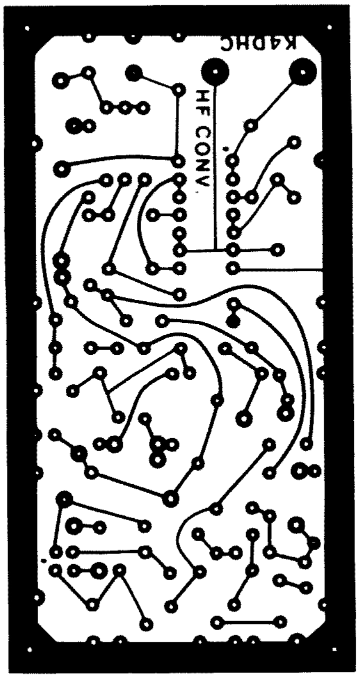

Fig. 2. Artwork for the PC board and component placement drawing.

remaining portion of the set screw to form a perfect 1/4" shaft. These extensions can be seen in the photo.

L1, the VCO inductor, is mounted on the PC board. L2 and L3 are wired directly to the terminals on the associated tuning capacitor with L3 cemented on top and L2 cemented to the back. Connections between the variable capacitors and pads on the circuit board can be made with bus wire for rigidity. Other connections can be made with ordinary hookup wire.

A copy of the front panel layout I used is shown in Fig. 3. The 2 vernier drives were miniature 10:1 planetary types by Jackson Bros. and were built into a standard 3/8" bushing. The pot, toggle switch, and rotary switch were all of the miniature variety so as to fit into the limited panel space. The battery status indicator used as phase lock meter was 1/2" in diameter. The cabinet was a Radio Shack 270-252.

As for choice of components where not specified, I used a pair of germanium diodes of unknown caliber for D1 and D2. The popular silicon 1N914 should work well here too. For the tuning diode, D3, an epoxy "bullet" rectifier diode worked best. Here again, there is room for experimenting and you might even want to try a real varactor diode if one is available.

The PNP VCO transistor I used was house numbered so I don't know the type, but just about any high frequency unit should be satisfactory.

All resistors are 1/4 Watt except the 300 Ohm dropping resistor which supplies power to the SN7400N IC. This is a 1/2 Watt unit.

The coil data provided in Table 1 is that used here. As mentioned earlier, these specifications will vary with the type of tuning capacitor used. The inductors are all wound on toroids and I used what I had available. Some substitutions as to mix and size can be made to harmonize with the inventory in your junk box.

Operation and Adjustment

Calibration of the VCO dial and the tuner dial are the first things to be done. I used a signal generator to feed into the tuner and observed resonance on a high frequency scope connected to the output. Not everyone has such a scope, so a high impedance detector and a meter could be substituted. Another method suggested in the original article was to place the tuner in series with the antenna input of a calibrated receiver, and the null in receiver response would indicate resonance of the tuner at the frequency indicated on the receiver. By whatever means you choose, mark off the frequencies of interest to you for both the high and low bands on the tuner.

Pad 6 on the PC board is a VCO monitor point. Here again, I used my scope to check frequency, but when this is not possible, a counter might be used or a well-calibrated receiver. The turns on the inductor may be spread or bunched together in order to shift the operating range of the VCO a fair amount if needed. When you finish calibrating, it would be best to cement the coil to insure stability.

A regulated power supply should be used to provide the operating potential of 12 volts. It might also be a good idea to check the voltage level

at pin 14 of the SN7400N to make sure it is between 5.0 and 5.5 volts. Some ICs may draw more or less current than others and require a different dropping resistor.

One consequence of operating a VCO over a broad frequency range is the drastic change in the ratio of varactor capacitance to tuning capacitance which occurs as the circuit is tuned over its operating range. At low frequencies, the diode capacitance is swamped by the variable capacitor, and hence the diode has very limited control over the frequency. At the high end, the diode dominates the tank circuit capacitance and exerts far more influence over resonance than the tuning capacitor. All this means is that at the lower frequencies, lockup is far more subtle and requires careful adjustment, while at the high end, just the reverse is true. The VCO snaps in with a vengeance on the higher frequencies. Lockup can also occur at fractional intervals and such points become more pronounced as frequency is increased.

During actual operation of the converter, the technique employed for setting the VCO is quite simple. First set the VCO to the desired frequency with the loop open. Adjust the bias for mid-scale reading on the meter and close the loop. Carefully search for lockup around the desired frequency. As you get close, the loop will capture the VCO and the meter will make a rapid excursion either up or down. Once lockup occurs, the meter will follow any slight tuning shift of the variable capacitor. You can also tell by listening to the receiver whether or not the VCO is locked. If you are operating on a whole number frequency, a birdie will be heard at any whole number dial setting of the receiver. If phase lock has not occurred, you'll hear all kinds of birdies up and down the band. Don't forget to check the bias whenever changing VCO frequency.

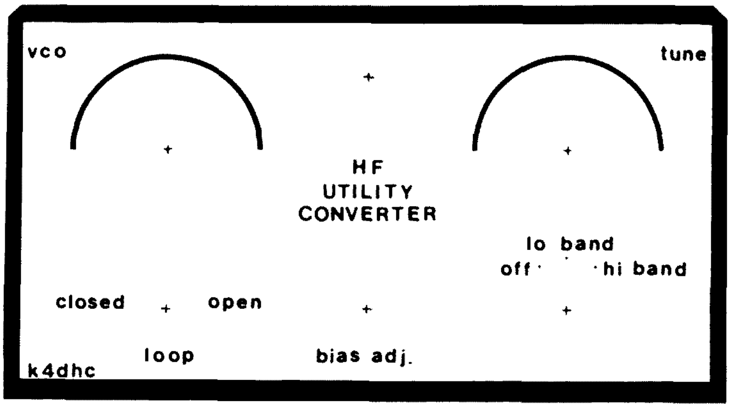

Fig. 3. Full size front panel artwork for the author's model.

With my 3.5 to 4.0 MHz tunable i-f, I set the VCO to 11.0 MHz for reception of the 40 meter band. For 20 meters, I have a choice of either 10.5 or 18.0 MHz. For 15 meters, either 17.5 or 25.0 MHz can be used. For 10 meters, I set the VCO to the low side since my unit stops at about 30.0 MHz. Since operation of both the VCO and the tuner is continuous between the abovementioned ham bands, you can set things up to listen to any portion of the spectrum in between.

Just for kicks, I found I could lock the VCO at 23,250 MHz and tune the CB band from 26.75 to 27.25 MHz using my 3.5 to 4.0 MHz i-f.

Conclusion

As I've tried to point out, I consider this converter more of a tool or test instrument than any kind of permanent receiver accessory. As such, it has no rf stage, the selectivity is limited, and no measures were taken to reduce spurious signals. You will find fairly strong birdies every MHz on the receiver and, if the VCO is set at a fractional frequency, it will cause a corresponding birdie in the receiver. For real serious listening, a more practical approach would be called for, including shielding, filtering, and an rf stage with bandswitching. Just the way it stands, however, I've gotten more use out of this gadget than any other tool on my bench. Have fun! ■

RTTY Scratchpad Memory

-- after this, try a UART

This article describes an erasable RAM memory for RTTY application. The memory is meant to be capable of storing 2 teletype lines (128 characters) of Baudot characters and reading them out at machine speed.

Thus amateurs who do not have a tape reader may type and store a message and play it an infinite number of times. The memory content may be erased and changed as desired as it is "volatile" – it disappears as the power is switched off and may be overwritten. If a fixed message is also desired, a ROM may be programmed and added or substituted for the RAM.

The RAM memory is substantially cheaper, but less flexible then the FIFO type memories such as used in the UT-4.

The circuitry is designed for use in combination with a UART (e.g., UT-2), but may be easily converted to run without it.

Principle of Operation

The heart of the memory system is a 1024 bit static RAM and its appropriate addressing logic.

To write into the RAM, a proper baud rate clock (e.g., 45.45 Hz) is enabled to advance a chain of SN7493 binary addressing counters by 8 per Baudot character. Synchronously, the start bit (1), character bits (5), and stop bits (1-1/2=2) are read serially into the RAM data input. Thus, a 1024 bit RAM can store (1024/8) 128 Baudot characters. To read the memory content, the binary addressing counters are clocked at baud rate, and the RAM content is displayed serially at the data-out pin of the IC. Means are provided for multiple or single read cycles, resetting, and displaying the half and full cycle memory address with an LED indicator.

Circuit Description

IC1, a 555 timer, is used as a master clock. If used for both, the RAM plus a UART, it should run at 16x the baud rate. If used for the RAM memory alone, it should run at the baud rate (e.g., 60

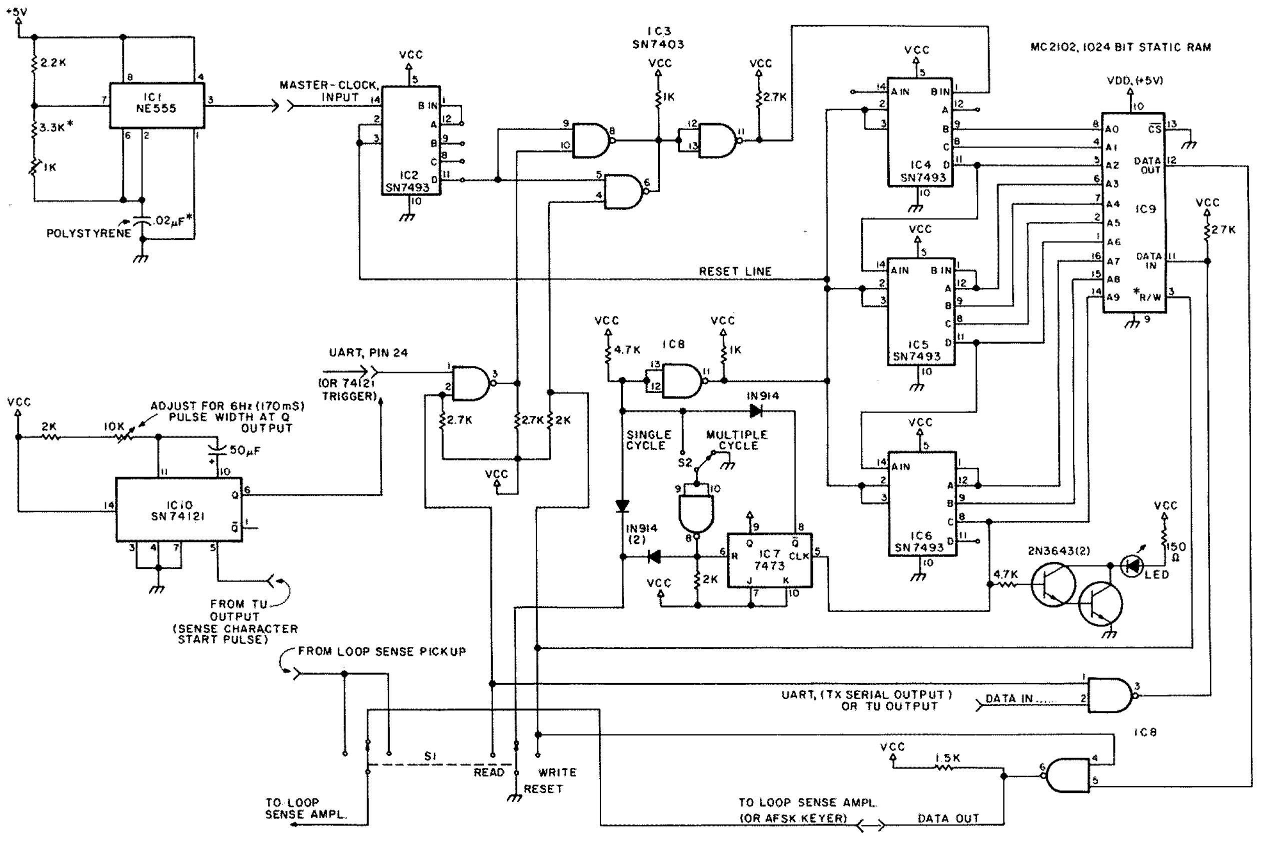

*Fig. 1. Master clock. RAM memory board, for Baudot type RTTY character storage. *Values shown are for 728 Hz (16 x 45.45 baud). **Note: low = write; high = read.*

wpm = 45.45 baud). IC2, an SN7493 4 bit binary counter, may be deleted since it only attenuates the clock speed from 16x to 1x. It is only needed if the clock is used for a UART circuit at the same time. IC3, an SN7403 NAND gate, enables and disables the clocking of the binary SN7493 addressing counters (IC4,5,6) for the RAM. These gates enable the clocking of IC4,5,6 for the duration of 1 Baudot character, that is, they advance the addressing counters by 8, and therefore enable the sequential writing or reading of 7-1/2 (8) bit Baudot characters. There are 2 unused counter outputs, which may be used for the addressing of 2 further RAMs. IC7, an SN7473 flip-flop, decodes a stop pulse when the RAM has cycled through all addresses. One half of IC8, a 7403 NAND gate, provides the switching for "reset" and "multiple" or "single" RAM cycles. The other half of IC8 serves as data input and output buffer. Transistor T1 switches an LED indicator "on" at the half cycle mark and "off" again at cycle completion, thus providing some indication of the cycle status.

If the circuit is not used in combination with a UART (e.g., UT-2), the IC3 gates must be switched from an alternate trigger circuit. An SN74121 monostable flip-flop, with an accurately calibrated time constant of (1/7.5 x baud rate), may be used to decode the start bit of a character and activate the clocking gates (IC3) for 7-1/2 (8) counts.

The RAM scratchpad has been used at my station for several weeks. I use it to loop CQ messages or for copying and replaying a couple of lines of my partner's RTTY transmission.

The circuitry fits easily on a 3-1/2" x 5" board, and the components were purchased for about $8 from James Electronics, California. ■

Build This CW Filter

- - darned good

To eliminate the frustrations of QRM and avoid the high cost of crystal filters, many hams employ audio filters. Usually, these take the form of passive networks which are often lossy and may require hard-to-get inductors. They are also virtually impossible to tune at these frequencies.

Such problems can be solved through the use of active filters. The filter shown in this article is a single-section, parallel-tuned configuration which uses a negative impedance converter, or "gyrator," to replace the inductor. Basically, the gyrator's input impedance is the inverse of a reactance placed in its circuit. In this case, a capacitor C_L is gyrated from 0.0332 uF to an effective inductance of 1.87 henries. Values up to 100 henries and Qs over 200 are possible with this circuit. Unlike passive filters, this has a 6 dB gain at resonance and virtually a zero Ohm output impedance. The circuit shown has a bandpass of 85 Hz centered at about 865 Hz. With the transformer shown, the op amp can provide plenty of volume to drive headphones. It operates from a single supply of 12 volts but can be used with a dual supply (e.g., two 9 volt batteries). Circuit Q is controlled entirely by R_S, which may be made switchable to provide various bandwidths. Provision can also be made to tune the filter with a single potentiometer. C_L and C_T should be fairly high quality mylar or polystyrene, and the four resistors, R, should be matched to about 2%. Nominal values for R_S lie between 50k and 300k. Approximated design equations are shown in Table 1. ■

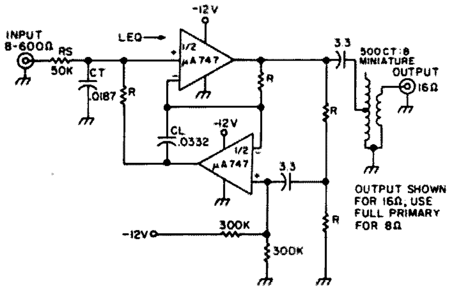

Fig. 1. Schematic. 850 Hz filter. R—7.5k.

$$Q = F_R/BW = 2R_S/(2\pi F_R \cdot L_{EQ})$$

$$L_{EQ} = R^2 C_L$$

$$F_R = 1/(2\pi\sqrt{L_{EQ} \cdot C_T})$$

The London Bus Tuner

- - effective for short antennas

A better, but less interesting, title for this article might be "a programmable, compact, medium power antenna matching device." The London bus comes into the affair because in searching for a way to inexpensively house an antenna matching network, we recalled the ticket dispensing machines used by attendants on the London buses – a machine which they carry with a large knob on one end.

One of the problems in housing any medium to high power antenna matching circuit, especially one using a rotary inductor, is that the construction cost starts to soar quite rapidly if one is forced to use a conventional large enclosure and a front panel turns indicator for the inductor. On the other hand, the use of a continuously variable inductor is superior to a fixed, tapped inductor if one wants to have a matching circuit which will accommodate a wide range of impedances on any HF band. This article mainly presents a few construction ideas and suggestions for housing a wide range antenna matching circuit at reasonable cost. Dimensions are given for one specific circuit, but they can be scaled up or down depending on the specific components used.

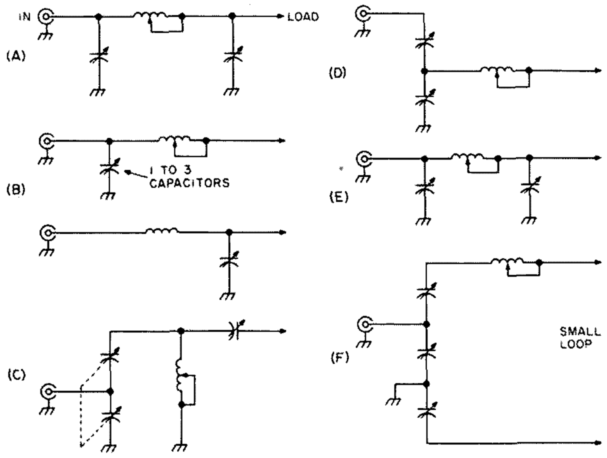

Fig. 1. These are some of the matching networks that can be formed by the interconnection of four "floating" components – a variable inductor and three single section variable capacitors. Component values are discussed in the text.

The circuit described in this article consists of just four floating components – three variable capacitors and a variable inductor. By keeping these components above ground and providing for their internal interconnection (programming), a variety of matching circuits can be formed as shown in Fig. 1. Each form can have its particular advantage, depending upon which band from 160-10 meters is being used and what form of antenna one is trying to match. The circuit possibilities range from simple L networks to a "transmatch"-type circuit. Besides matching networks, the components can be interconnected to form simple one section low pass, high pass, or trap-type filters for experimental purposes. This flexibility is often useful when one wants to quickly set up a trap or other type LC circuit for experimental work in a transmitter or receiver.

The inductor used is a standard Johnston 28 uH unit. Various surplus types of the 18-33 uH size, such as from the Command Set series, are also usable. In fact, it often pays to buy one of the old transmitters just for the rotary inductors! With 300 pF capacitors rated at 1500 volts, just about any antenna form can be handled up to the 500 Watt level from 160-10 meters. With 100 pF, 2000 volt units, a kW can usually be handled from 80-10 meters. Towards the other end of the scale, if one is using a barefoot rig of the 150 Watt category, the use of the reasonably priced and more readily available Hammarlund MC325M variables (325 pF, 1000 volt) is a good choice for 160-10 meter capability.

The whole subject of finding variable inductors and capacitors at "amateur" prices for anything above the QRP level could develop into an article by itself. About the best that can be said is that bargain hunting still pays off. For instance, all the electrical items for a 500 Watt level matching circuit could be found for $18 at Fair Radio, PO Box 1105, Lima OH 45802. The items a surplus house has in stock are in a constant state of flux, but usually something suitable can be found. Don't overlook the old BC-191/BC-375 tuning units and the previously mentioned ARC-5 (Command Set series) transmitters. They often are available at reasonable prices, although the variable capacitors/inductors have odd shaft sizes and call for a slight bit of mechanical ingenuity to use.

A matching circuit using a 28 uH rotary inductor and three 100 pF, 2000 volt capacitors was housed in an inexpensive 9 x 6 x 5 inch enclosure (Bud CU1099). The inductor was placed parallel to the long side of the enclosure. The turns counter assembly is simple but effec-

tive (see Fig. 2). A 5 digit left-hand drive veeder root count (Burstein-Applebee #18A1507-3 at $1.49) has its ½" belt drive wheel driven by a 2" belt drive wheel placed on the rear shaft extension of the inductor. The 2" drive wheel and rubber belt used were junk box tape recorder parts. The counter reads from 0 to about 600, and this is enough accuracy to ensure resettability to a fraction of a turn. Many other similar mechanical turn counters can be used.

The three capacitors were directly mounted on an approximately 8 x 2 inch piece of piexiglas. This plexiglas plate was mounted to the panel of the enclosure with regular metal hardware with about a 1½" standoff from the panel. Insulated shaft couplings were used on each variable to complete its insulation from the enclosure. Leads from each component (# 16 or # 14 hookup wire) were routed to a long barrier terminal strip (similar to Radio-Shack 274-670) mounted on the rear inside panel via an insulating piece of plexiglas. Short pieces of wire with spade lugs at each end are then used to interconnect components as desired. Only two SO-239 coax receptacles show on the rear outside of the enclosure. One could, as an alternative to the above, bring out each component to binding posts on the rear panel. But, since high rf voltages may be encountered, this would require that the posts be mounted on a piece of plexiglas which in turn is mounted over a cutout in the rear panel.

If one has some pre-knowledge of the impedances to be matched, a specific matching circuit configuration can be used immediately. Otherwise, the pi-network of Fig. 1(a) or the circuit of Fig. 1(c) are always good ones to start with. Note that the "transmatch" circuit of Fig. 1(c) normally uses a dual variable, so the two single variable capacitors used instead have

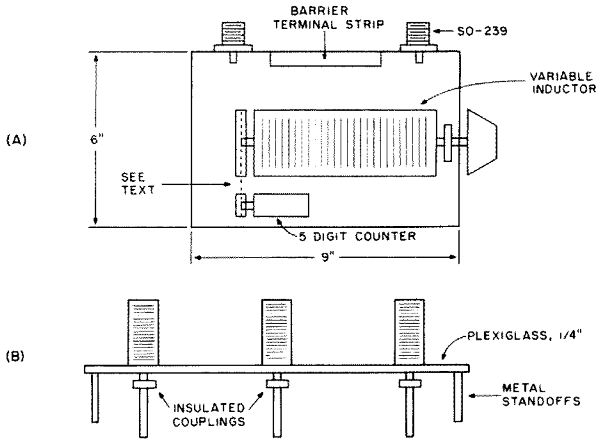

Fig. 2. Compact construction of a medium power tuner in a 9 x 6 x 5 inch enclosure. (a) Top view without capacitors. (b) Capacitors mounted on a piexiglas strip, which in turn is mounted above the variable inductor by standoffs to the front panel. Details are in the text.

to be simultaneously rotated to simulate a dual variable. One can then try other matching configurations to achieve the best transfer of power. Generally a good rule of thumb is that the matching circuit which uses the *minimum* amount of inductance to match into the load *and* which provides a clear swr minimum on the coax line between the transmitter and the matching circuit will be the most efficient circuit to use. To see which circuit does this is easily facilitated by logging the turns counter readings for the variable inductor. ■

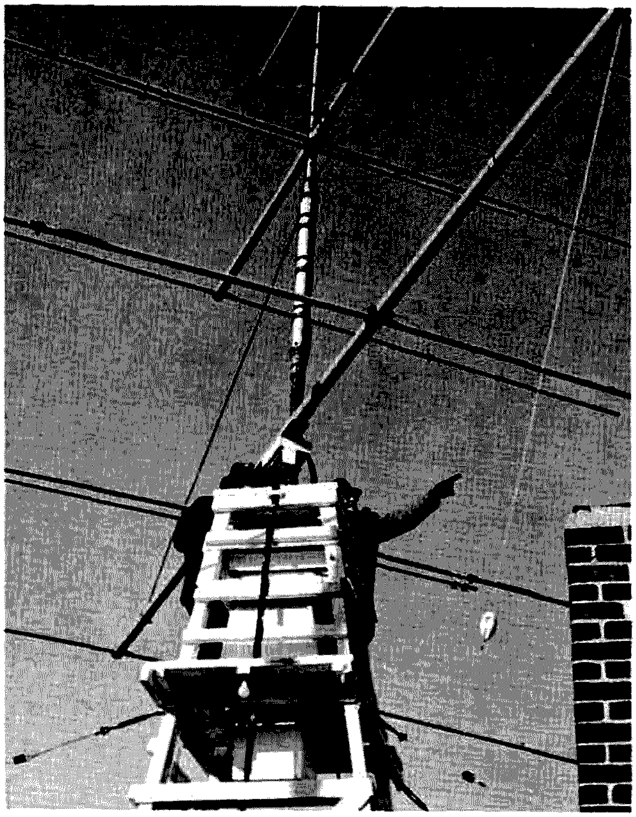
The WIBB Story

-- a visit with the king of 160

What started out as a simple journey to Winthrop, Massachusetts, for Stan WA1UMV and me, to take a picture for the cover of 73's new publication about the 160 meter band, *The Challenge of 160 Meters!*, quickly turned into one of the most interesting days I have spent since becoming involved with amateur radio.



W1BB and the author atop one of Stew's towers. The tower was built in the 1930s and is located atop the house on Pleasant Street, Winthrop MA. Stew is indicating the way to Europe.

What, you may ask, were we doing in Winthrop MA to take a picture for a book about 160 meters? Winthrop is the home of 160 meters' most distinguished and recognized enthusiast, Stewart Perry W1BB.

I spoke to Stew by phone a few days before, and he invited us down to take a picture of some of his prize QSL cards. The cards were those he had used to obtain the first DXCC certificate issued exclusively for 160 meter operation.

As we drove up in front of Stew's house, it was not hard to recognize it as the home of an avid ham. Besides the numerous antennas on the roof of the large Victorian two story home, there was a convertible parked in the driveway which carried a whip antenna with the largest loading coil I've ever seen. In fact, the cover for the coil was made from an inverted plastic trash pail. On the paii was written W1BB/160.

We were greeted at the door by Stew W1BB, a very distinguished looking gentleman, who escorted us to his ham shack on the second floor.

As we walked into the room, it was like taking a step back in time. There in front of us was the shack of yesteryear — the type of place you would visualize when reading about the early days of radio. Yet intermingled among the vintage equipment was a modern up-to-date amateur station.

Stew explained that this station was just one of three he operates. It, however, was the oldest, and most of the visible equipment was built around 1935. He had at that time built transmitters for every band from 160 through 2 meters and could, through a series of patch cords, QSY from one band to another in a matter of seconds.

He demonstrated his first transmitter for us. It was a spark unit, and the noise was deafening. In the corner was a giant knife switch. Stew explained that such a switch used to be required for lightning protection, and this particular switch was used to ground his 160 meter doublet (which was fed with 600 Ohm open wire line). Next to it was an allband tuner which employed three variable capacitors, plug-in coils and an rf ammeter in each feedline leg.

Stew's two other stations consisted of a smaller station

in his bedroom for those late night openings and a larger station at the site of the Winthrop water tower, where, in addition to operation for the Winthrop Emergency Radio Net, for which he is radio officer, Stew has permission to conduct some of his 160 meter tests. The tower braces Stew's 160 meter inverted vee beam 265 feet above the ocean's surface.

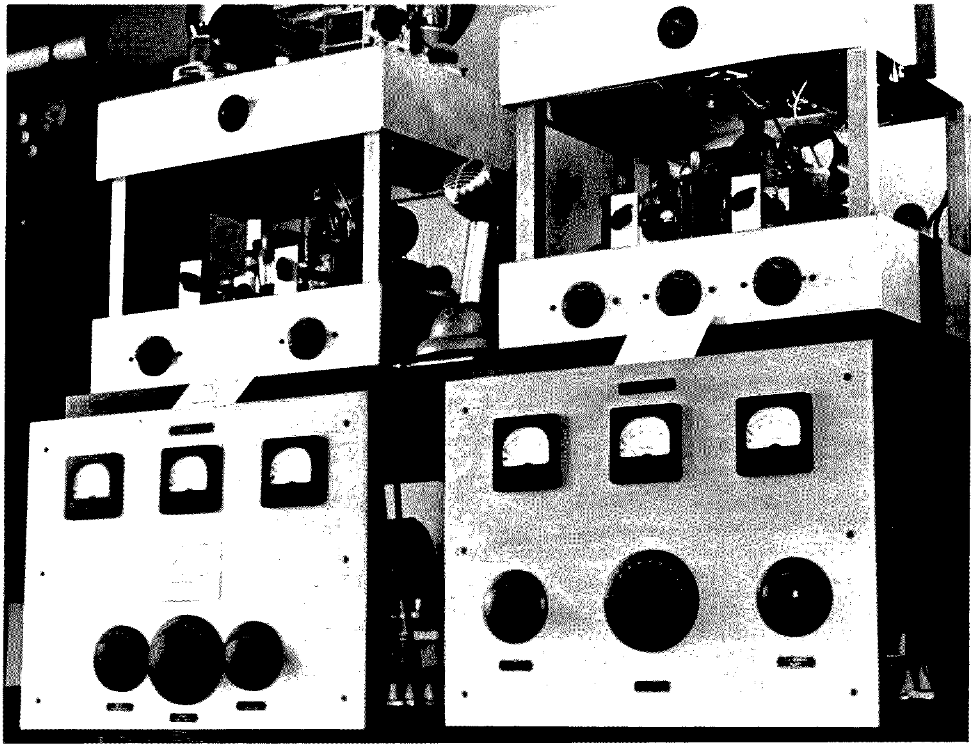
While Stan took pictures of the shack and QSLs, Stew and I went into the kitchen, where, over a cup of coffee, I found out how Stew Perry W1BB had, over a period of 65 years, come to be one of the best known and respected gentlemen of the "gentlemen's band."

The Perry family has lived in the same house on Pleasant Street since Stew's birth in 1904. When Stew was 8 years old, his interest in radio was kindled by a neighbor. As he tells it, one day he was playing in his backyard when his next-door neighbor Eddy O'Toole, who was always interested in scientific things, called him over to show off his new crystal radio. Stew listened and heard dots and dashes. Eddy explained they were coming from the Boston Navy Yard (NAD) and were talking about a large ship which had recently sunk. Well, the ship turned out to be the Titanic, and the incident was the start of Stew's interest in radio. Of course he wanted to make a radio, and Eddy told him how to do it. All he needed was a Quaker Oats box, some wire, a slider, and a galena crystal. So he went to Bin's Radio in Boston and purchased the materials, and it wasn't long before he was listening to NAD.

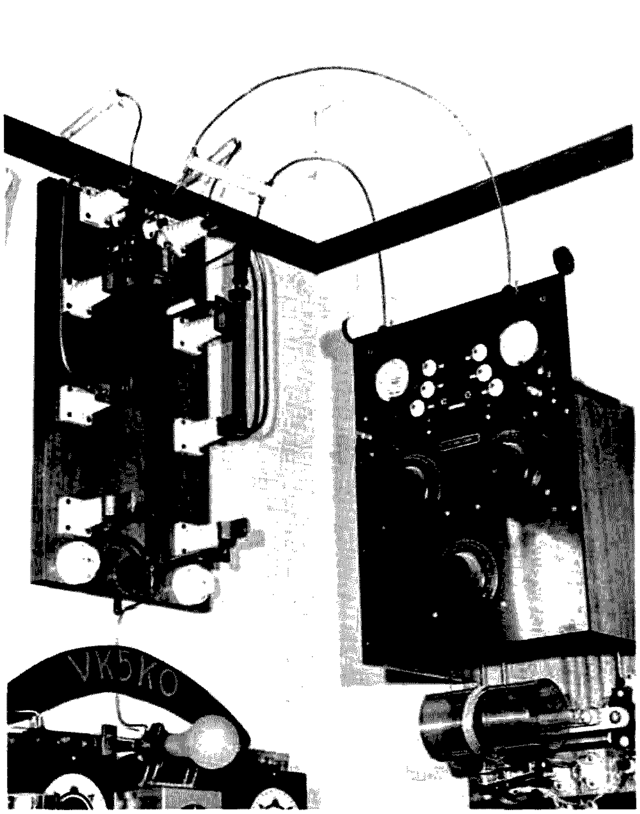
It was right after this that Stew managed to obtain an old Ford spark coil and get on the air himself. In those days, no one had a license, he explained, and he signed the call SS, which are his first two initials. Stew thinks they were operating somewhere around 500 meters, but no one really knew the exact frequency. The estimate was based on NAD, which used to call Stew once in awhile to ask that he QRT because he was interfering with them. They were operating near 500 meters. The first contact Stew had was with Eddy O'Toole, his next-door neighbor, which was followed by others with people in the neighborhood.

After a while, licenses started to be issued for radio operation. And as Stew puts it, "Those with licenses would squeal on those without them." So he decided to get one. He went to the Customs House in downtown Boston and took the test. It consisted of a 5 word per minute code test, which you had to pass before taking the written exam. The written part was all essay-type questions and covered theory, rules, and regulations. One part of the exam was to draw a complete diagram of a station, including a receiver, transmitter, and antenna system. Another question was to explain how radio frequency waves were generated, starting at the power lines and ending with the antenna. Other questions dealt with

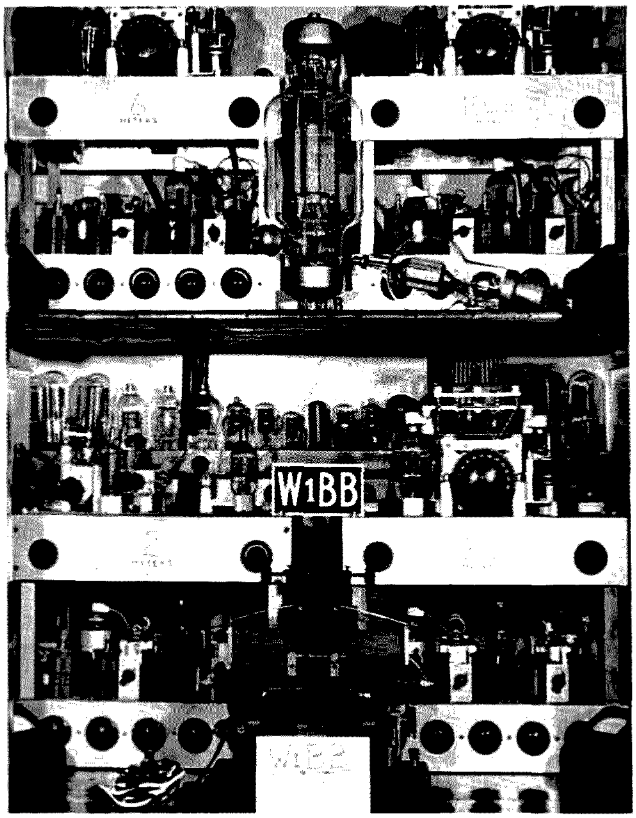
Whip antenna mounted on W1BB's auto. The loading coil is covered with a plastic trash can. Stew worked mobile on 160 meters for over 25 years, using both AM phone and CW.



Several of W1BB's transmitters built circa 1935. These transmitters could be switched from one to another in a matter of seconds.



The large knife switch in the corner of W1BB's station on Pleasant Street. The switch was used to ground his 160 meter antenna for lightning protection. Next to the switch is an allband antenna tuner.



Some of W1BB'S switchable transmitters built around 1935, as well as his spare tube collection. In the forefront on the bottom shelf is one of his original spark transmitters from 1912. A demonstration proved the noise from this unit to be deafening.

such things as Leyden jars and mud capacitors. Stew said it was an easy exam if you knew about radio. As luck would have it, he passed the exam on the same day war was declared – the beginning of World War I. He was issued his operator's license, but not a station license.

After the war, word came down that station licenses were to be issued. Stew thought that it would be nice to get 1AA (at that time W prefixes were not used), so he got up at 4 o'clock in the morning and went to the Customs House only to find that others had the same idea and were already in line. As it turned out, he was issued 1BB, which he has held ever since.

At that time hams were given the frequencies of 1750-2000 kHz, the forerunner of today's 160 meter band. According to Stew, they used to try to operate as close to the bottom of the band as they could but the spark transmitters were so wide that a signal on 160 meters could be heard from 100 meters to 250 meters. Hams tried to sharpen their signals by using a helix auto transformer, which consisted of a tank coil of about 15 turns and a variable link of about 7 or 8 turns, but it did not help very much. Signals were never sharp until the advent of the vacuum tube.

While it was illegal to operate during World War I, Stew studied and managed to obtain his commercial radio license. As a result of this license, in 1920 he went to sea as a commercial operator, operating in the 500 meter band. His life at sea was to last, on and off, for the next six years.

In 1932, the 160 meter trans-Atlantic tests began. These tests were sponsored by a group of British hams, including G2II and G2PL, and were conducted every Saturday morning at European sunrise. American hams would call for the first five minutes past the hour, and then listen while the European hams would call for the next five minutes. When a contact was made, the calling schedule would stop. At this time no one thought of counting countries – just getting a trans-Atlantic contact was excitement enough.

After the tests had been conducted for a few years, hams did start counting countries. In 1935, W1BB listed Belgium as country number 1, after receiving a QSL from ON4NU. Others also started counting, including W1LYV, W2IV and W2EQS.

By 1968, 33 years later, Stew had confirmed his 100th country with a card from CE3CZ in Chile. He now has 139 confirmed on 160 meters alone.

Stew says it's now easier to work DX on 160, due to the fact that more is known about the band. We have better antennas and better receivers, and propagation is better understood. For example, in the beginning no one considered opening during American sunsets. All DX was worked during European sunrise. But now it is known that the band also opens for a couple of hours after the western sunset. Antennas have also changed. Early hams used Zepps and horizontal doublets. Now we find that verticals, inverted vees and inverted L's work better as transmitting antennas. Also, it is now known what countries can be worked on 160 and schedules can be made.

As to the type of antenna Stew would suggest for 160 meter work, he says an inverted L type with a good ground system is the simplest. And he stresses a *good ground system*. The inverted

L, he explains, is nothing more than a top-loaded vertical. In stressing the point about the ground system, he uses the example of ZE7JX, who needed to work Australia. He started with a few ground radials and kept adding more and more. Before he achieved his goal, he had buried more than 16,000 feet of wire but had kept the antenna the same. Stew has a ground system which he installed in 1940. It consists of 7' X 4' zinc plates, connected together like the spokes of a wheel, with the antenna in the center.

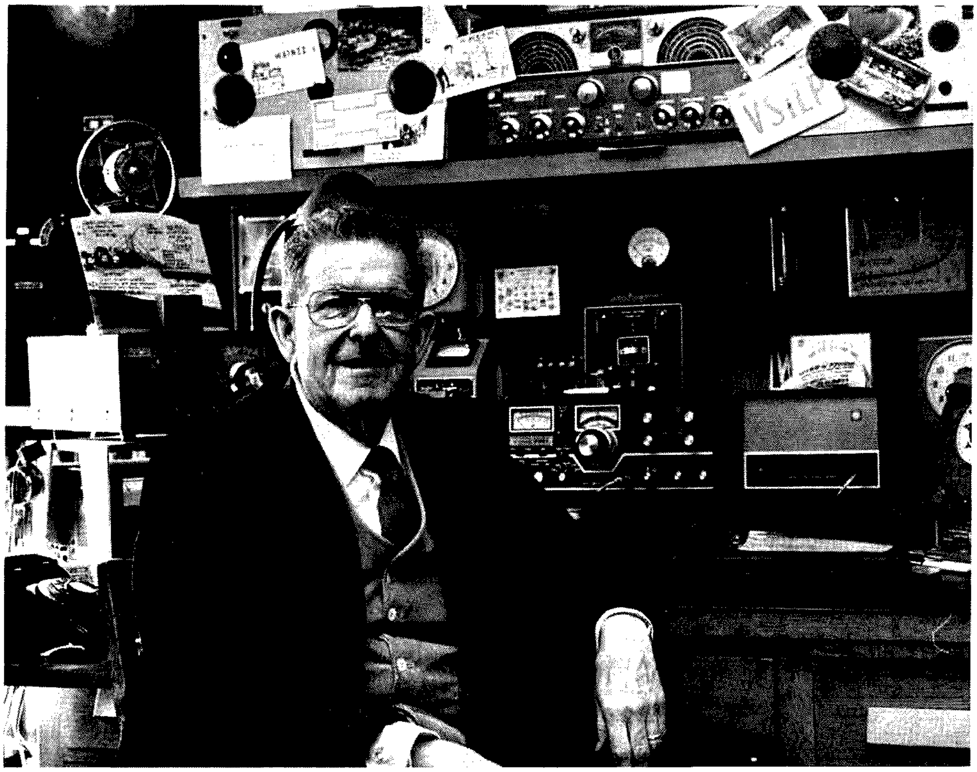
As for receiving in a quiet area, a resonant antenna such as a sloping dipole or a vertical is suggested by Stew. However, in a noisy area the beverage antenna is best. A beverage antenna is a long long wire terminated with a resistance for directivity. It is run close to the ground and does remarkably well. Experiments have also been conducted while running the beverage antenna underground and underwater. Stew has used an underwater beverage with a length of 150', 6-7' below the surface. He says the results were spotty. KV4FZ has achieved great success with an underwater beverage 300' in length, 4-6" below the surface.

Stew sees a bright future for 160 meters, marked by increased activity. As long as the newcomers abide by the unwritten rules and observe the "DX window" (an area historically reserved for foreign stations from 1825-1830 kHz), the band should offer many hours of enjoyment to hams.

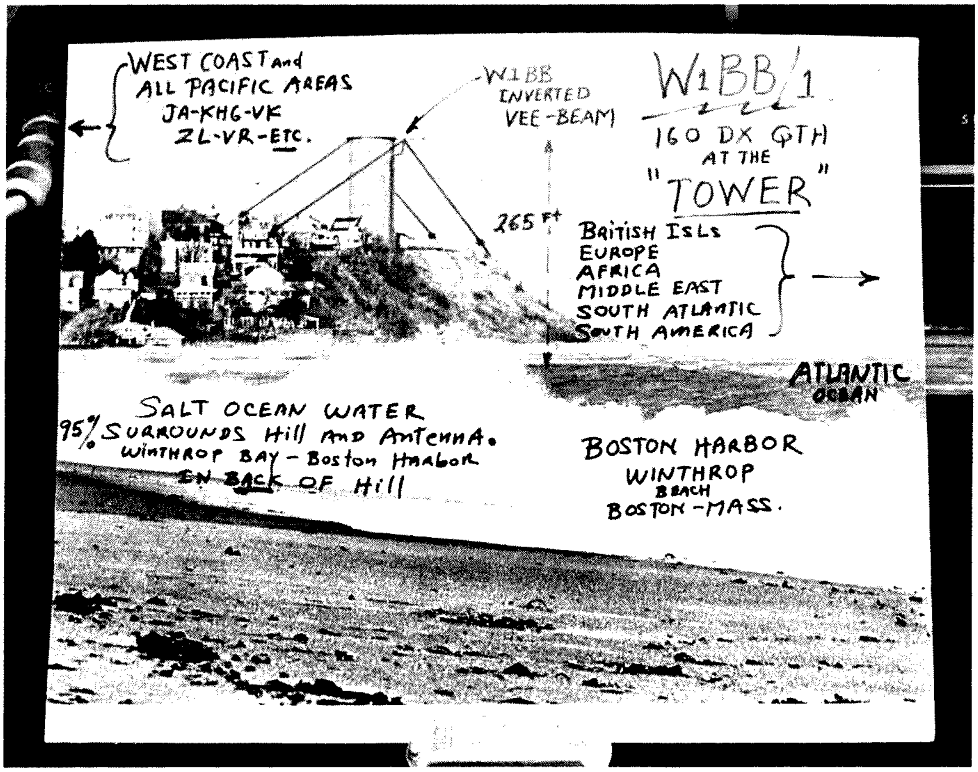
Aside from his accomplishments on 160 meters, Stew also works other bands and has the capability of going on any band from 160 to 2 meters. He seems to work 20 meters the most, often checks into 80 meter nets, and gets on 40 occasionally.

Stew's reaction to the recent FCC proposals to be offered to WARC is that they look very well thought out. He was surprised to see that they proposed the 160 meter band go back to its original starting point of 1750 kHz. He had hoped that the band would be left as it stands (but with the elimination of Loran).

To express how a shift in



Stewart Perry W1BB, whose station has been in use since 1912. Stew holds the first DXCC issued for exclusive 160 meter operation.



W1BB's secondary station location, showing the position of his inverted vee beam strung from a water tower 265 feet above the Atlantic Ocean.

frequency makes a dramatic change in the propagation of signals on the 160 meter band, Stew relates the story of HB9CM. It seems that HB9CM was working a stateside station on 1827 kHz and received a signal report of RST 449. He decided, for experiment's sake, to go up to 1995 kHz to see if his signal strength would change. He came up to an RST 579. And that, Stew says, is sometimes the difference between the top and bottom of the band when the MUF is just right. "And," he adds, "we used to all try to stay as close to the bottom of the band as possible. In those days, it was thought the lower frequencies were the best for DX."

As to the proposed 1875 meter band which the FCC will include in its recommendations to WARC, Stew does not see it being anything like 160 meters. He thinks the band, if it is ever approved, will be more akin to two meters in its range and application.

After concluding my discussion with Stew, we all departed to the site of his station at the Winthrop water tower. Standing on top of the cliff next to his two element inverted vee beam antenna 265 feet above the Atlantic Ocean, Stew stretched out his arm and said, "That way's Europe." He moved his arm and said, "That's North Africa." He moved it a little more: "And that's South Africa." It was a site to make any DXer's heart green with envy. Here was a man who did what many had thought was impossible. He managed to be the first to work 100 countries on 160 meters, after 33 years of operation. For Stew, though, I'm sure it was not hard, because he enjoyed every minute of it. It is only right that a person who feels so much good for something should excel at it. He is a real gentleman from among those on the "gentlemen's band," 160 meters.■

Ten Watts On 2

-- it's possible with this rock crusher!

An easy to carry portable pack for your two meter FM rig is a great asset for any ham: to keep in touch at work, on hikes, during walk-a-thons or other public service events, and just to have more fun with amateur radio. Fortunately, making a decent and reliable portable carrying case, with self-contained batteries (rechargeable, of course) and antenna, only takes a bit of scrounging and care.

You'll notice that my efforts culminate in a rig that runs *ten* Watts output, not the usual 2 or 3 Watts of other portables. However, it isn't exactly hand-held, nor does it weigh a couple of pounds (the porta-pak tips the scales at 7½ lbs.). But the advantages far outstrip the drawbacks: much greater power output to hit the more distant repeaters reliably, no great outlay of cash for another transceiver (you use your present mobile rig), and the fact that most other hams I've seen carry their HTs on their belts anyway – so a shoulder strap rig is just as "hand-held" as theirs is!

The Rig

The first thing you need is an FM transceiver, of course. My Icom IC-22A is shown in the photos; any of the standard power 10 Watt rigs (Midland, Heath, Standard, Genave, etc.) could work as well. Even if your powerhouse runs 25 Watts out, it may have a low power mode which can be modified to run 5 or 10 Watts. Alternately, a home brew or module-type kit built rig, like the VHF Engineering units, could be made portable this way.

The Case

The case for the rig is a slightly altered cassette tape recorder affair (you used your recorder for slow scan anyway, now here's where the case can come in). It originally measured 28 by 19 by 7.5 cm, obtained at a local flea market for less than $2.00. These things are usually vinyl covered cardboard, stitched up as in the photos, and are surprisingly rugged. If you really want to be creative, have your local sweet young thing, wife, or even yourself throw together a custom job out of leather. Be sure to put a strap on it so you can sling it over your shoulder – and don't forget to leave room for the batteries!

The FM transceiver, in my instance, was a bit too large for the cassette carrying case, so I extended the cover flaps and used velcro as a securing device. Velcro is that material with zillions of little hooks on one surface and an equal number of loops on the other so that when you press the two together, they stick. A couple of small pieces (20¢ at the local fabric shop) hold very tenaciously and can be sewn, glued, or stapled to the case. Velcro is much easier to use and is just as strong and reusable as snap fasteners or buckles and straps. Besides, it makes that satisfying "rip" when you go to open the case.

Batteries

The rig sits on top of the battery pack, as you can see in the photos. This nicad pack has ten "D" size cells all strapped together and puts out 3.5 Amperes for a solid hour. With 150 mA receive current (all dial lamps on) and 2.2 A transmit draw for 10 Watts output, the pack runs all day and night in regular service without a recharge. If you don't want the rig to sit on top of the batteries, you can lay them end-to-end alongside the transceiver inside the case. Hopefully, you'll find a case thick enough for this – but mine worked great with the batteries at the bottom.

"C" size nicads will last nearly as long on a charge, but you'll be working them harder and they may poop out just when you need them most. Alternate energy sources are the newer gel-cell batteries, which have no nicad "memory" effect, and are somewhat less expensive. Lead acid wet cells are usable, and are sometimes available at Olson Electronics, flea markets, and surplus houses. Some battery manufacturers are listed at the end of this article. I imagine that if you could find a small motorcycle battery, it would work fine. A two Ampere-hour rate at one hour is about minimum for useful, long single-charge life from the battery power source.

Connecting the battery to the transceiver is not that much trouble, obviously, but taking a little more time to add a switch and connector makes the porta-pak more versatile. I used a small 3

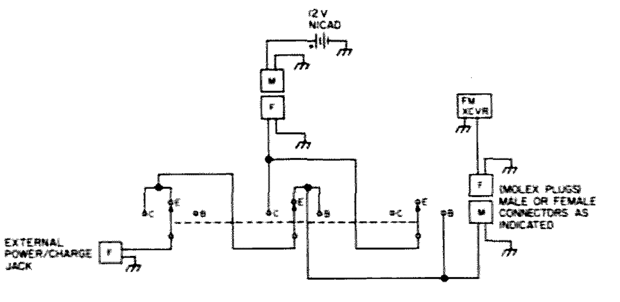

Fig. 1. Schematic of power switching for the portable rig. C – charger goes to jack for charging nicads; E – 12 V power to jack for external supply; B – battery connected to FM transceiver.

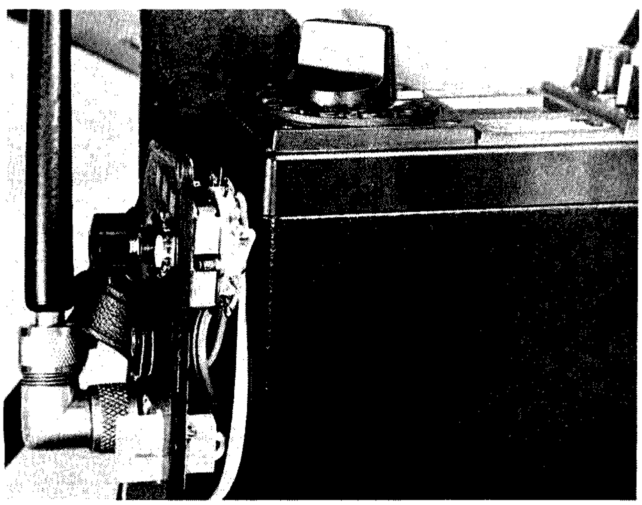
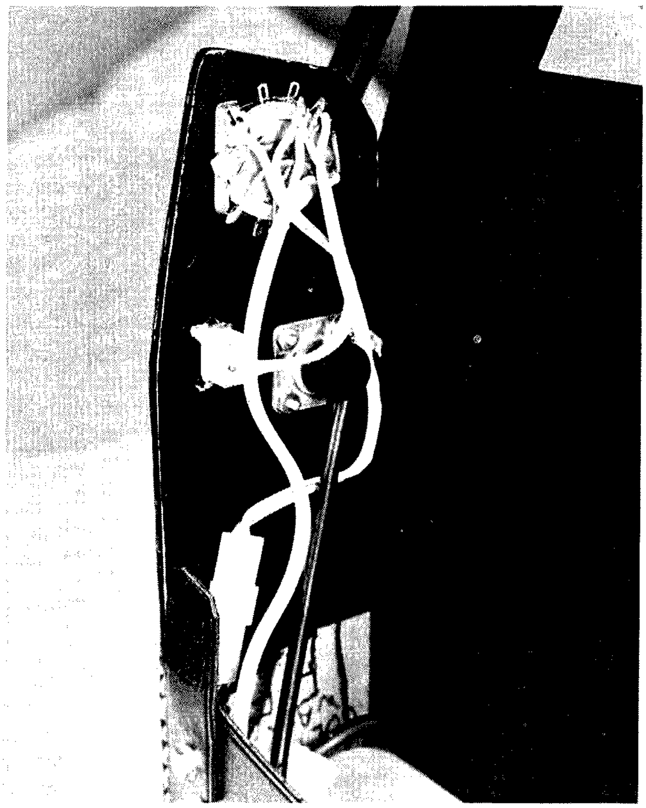
Right-front view showing microphone clip.

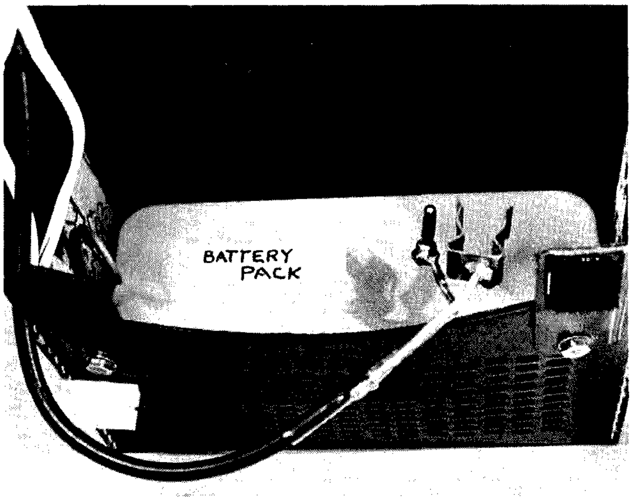
pole, 3 position rotary switch to either connect the rig to the battery, hook the rig to the external power jack, or connect the battery to a charger via the external jack. Fig. 1 shows the switching setup, and the mounting arrangement is visible in the photos. The external power/ charge jack can be epoxied to a carefully cut hole in the side of the case, while the rotary switch is mounted conventionally. I suppose that if there were more room in the carrying case, a charger could be built in. However, I found that the 12 volts available at the case's power jack when switched to the "charge" position is useful for running lamps, HF QRP gear, or other equipment from the nicads, without having to remove them from the case.



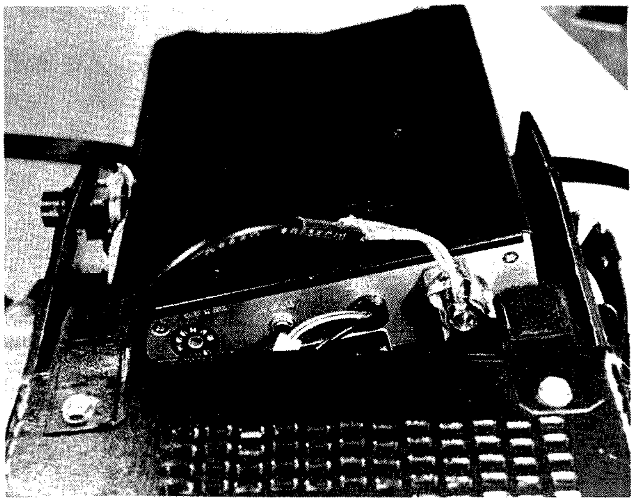
Close-up with top cover flap lifted.



Power switch and antenna wiring. Notice counterpoise wire running from SO-239 down far inside corner of case.



Coax connector with battery sitting in the bottom of the case.



Close-up of transceiver rear panel with coax connector.

Antenna

The antenna connection is about the most difficult thing to accomplish, since the rig sits upended on the batteries and the antenna jack sticks out of the transceiver's rear panel. Adding a coax elbow and associated connectors made the IC-22A jut too far out of the carrying case, so I made connections to a sawed-off banana jack and an old fuse-clip holder, resulting in a very shallow right angle coax connector. See Fig. 2 and the photos for more information. I found that solid #14 or #16 insulated wire worked best for 1½ inches between the home brew connector and the RG-58/U coax, preventing the flimsy coax braid and center conductor from breaking off at the connector while the rig shifts around slightly in its case. Use heat shrink tubing around the solder joints. At two meters, the connector is a bit lossy (10-15%), but it's the best solution to the problem of keeping the porta-pak as compact as possible.

I mounted an SO-239 antenna jack at the side of the case, and used a coax elbow here so that a rubber ducky, 19 inch whip, or external antenna can be screwed on. When I first used the portable rig, I was disappointed in the results because of the poor radiation efficiency. However, when I ran a 19 inch counterpoise wire from the SO-239 grounded mounting ears down around the bottom of the case, results improved as much as 20 dB! So the whip or helical antenna now acts as the radiating end of a vertical dipole, much more effective than the antenna alone stuck on the end of a short length of coax. Handie-talkie owners might try this trick too, since it really improves signal strengths. The wire doesn't seem to bother anything when the porta-pak is hooked up to an external antenna, since it is connected to the shield of the SO-239.

Results

I've been using my portable ten on two for nearly six months now, and have consistently out-talked and out-performed belt-mounted HTs. I didn't have to lay out $30 for an external mike, either! Once I worked several San Francisco Bay Area repeaters from Yosemite National Park – and was full quieting with the 10 Watt power level (I also had about 5,000 feet of height). I never have to remove the rig out of its case when used in the car or home, thanks to its provisions for external power and antenna. And, there is no problem with car theft – I take the porta-pak with me!

I've been to plenty of club meetings, amateur flea markets, and ham get-togethers with this little system, and if the interest generated in it is indicative of a universal appeal, many more will be built. I hope this article helps with some general guidelines and ideas, so you can more easily build your own 2 meter FM super porta-pak. ■

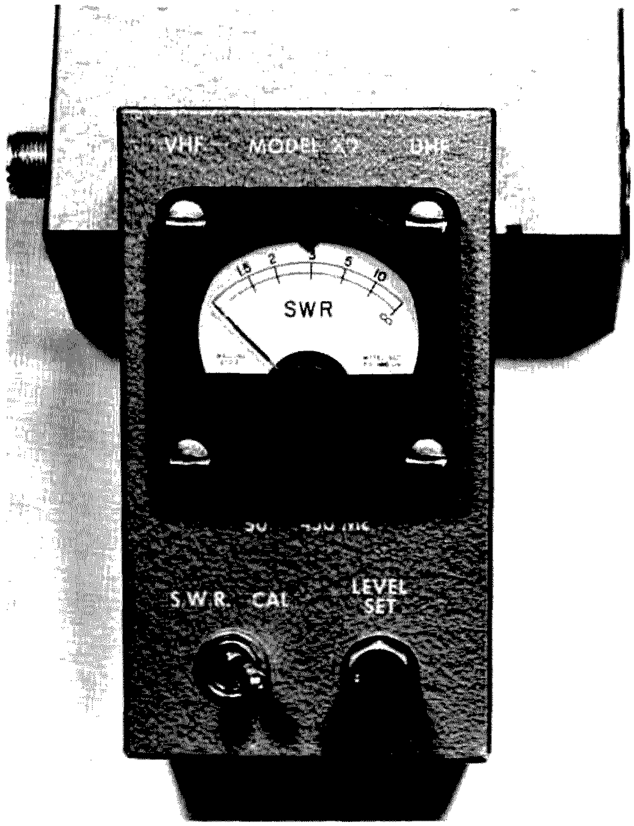
UHF SWR Indicator

- - 1296, anyone?

W. E. Parker W8DMR
2738 Floribunda Dr.
Columbus OH 43209



The line may be left connected in the transmission line, and the meter box conveniently placed on top of the transmitter.

There are many inexpensive standing wave ratio indicators that are listed as good up to two meters and do function well. At frequencies above approximately 150 megahertz the results leave something to be desired.

There are several valid reasons why the swr indicators are inadequate. In order to have good sensitivity at the lower frequencies (80 meters), the coupling loops used for forward and reflected wave sampling are usually six inches long, and are close-coupled to the center conductor of the transmission line. If the sampling loops are shortened and loosely coupled, then the sensitivity for the lower frequencies is greatly reduced.

Another reason for poor operation is that the coupling loops required for low frequency operation represent almost a quarter wave at the ¾ meter band (≈500 MHz). Distributed capacity between the long coupling loops and the inner coaxial conductor is excessive.

The diode rectifier characteristics become more important at the higher frequencies. The position of the pickup loops with regard to spacing, direction and concentricity must be very carefully aligned if their electrical characteristics are to be as similar as possible. Once aligned or positioned, the loops must remain rigidly affixed if a level of confidence in the indicator is to remain.

If the coupling loop is to be a small percentage of a wavelength (1/20 or about 5 percent), a length of one inch is about the maximum to be considered. If the indicator is to be used with low power transmitters (½ to 2 Watts), the loop should approach the one inch length. For high power transmitters, the loop may be as short as 1/8 of an inch. This is that portion of the loop that is parallel to the coaxial center conductor.

The coupling loops form a circuit with a resistor such that the mutual coupling is positive (+) in one case, and negative (-) in the other. The same effect could be obtained if a single loop was used for sampling, then rotated 180 degrees, and then sampled. Inspection of the equations that follow will show this is taken into account.

That portion of the loop parallel to the center conductor and the resistor form a third component, the distributive capacity element C. See Fig. 1.

The output rf voltage e_o is made up of e_r and e_m. A voltage divider is formed by distributive element C and R.

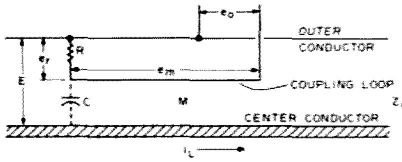


Fig. 1.

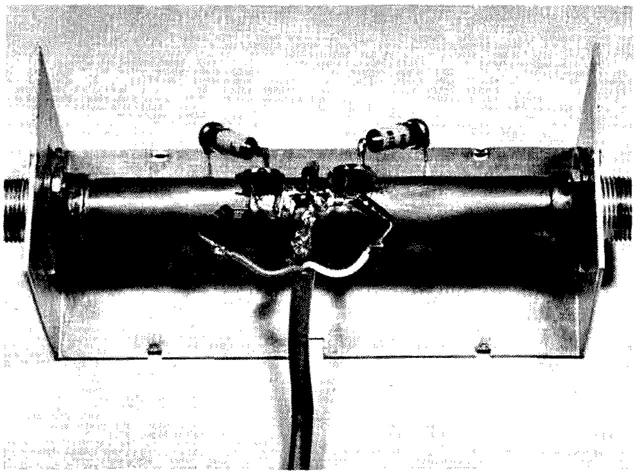
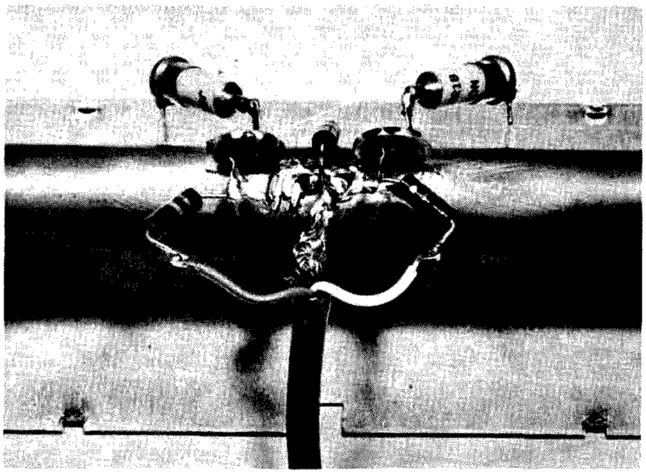


The ½ inch copper water pipe transmission line mounted in a minibox with components attached.



The edges of the button bypass capacitors have been soldered directly to the line. The 39 Ohm resistor is in the middle. A heat sink should be used when soldering directly on the diodes.

Then,

$$e_r = \left[\frac{R}{R + X_c}\right] E$$

and if R is much less than X_c,

$$e_r = \frac{RE}{X_c}$$

and since jwC equals $1/W_c$,

$$e_r = REjwC$$

$$e_m = I\ [jw\ (\pm M)]$$

by induction.

The sum of e_r and e_m is (factoring out jw)

$$e_o = jw\ (CRE \pm MI)$$

The directivity of the indicator, its ability to discriminate between the forward and reflected wave components, depends upon the relationship $CR = M/Z_o$, where Z_o is line impedance.

Substituting for CR,

$$e_o = jw\ (E\frac{M}{Z_o} \pm MI) = jwM\ (\frac{E}{Z_o} \pm I)$$

Another relationship must be stablished before again substituting in the rf output voltge equation for e_o. It is important to note capital letter E is used to designate the line voltage.

The voltage E at *any* point n a transmission line is the sum of the forward and relected voltages, or

$$E = e_f + e_r$$

It should be remembered that e_r during the next few equations represents the reflected voltage; it should not be confused with e_r, the voltage across resistor R.

Then,

$$I = \frac{e_f}{Z_o} - \frac{e_r}{Z_o}$$

The minus sign is because the reflected wave travels in the opposite direction.

$$I = I_f + I_r$$

where

$$I_r = -\ \frac{e_r}{Z_o}$$

There are two cases to consider: (a) when the resistor is toward the load; and (b) when the resistor is toward the source. So, substituting for E and I in the e_o equation for each case,

$$e_o = jwM\ \left(\frac{e_f + e_r}{Z_o} + \frac{e_f - e_r}{Z_o}\right) = \frac{jwM}{Z_o}\ (2e_f)$$

$$e_o = jwM\ \left(\frac{e_f + e_r}{Z_o} - \frac{e_f - e_r}{Z_o}\right) = \frac{jwM}{Z_o}\ (2\,e_r)$$

The equations show that the rf voltage from the loop before rectification is directional and proportional to the voltage in the transmission line (due to the forward and reflected wave respectively). Fig. 2 shows that even though E_s is zero, E_r and E_f are still present.

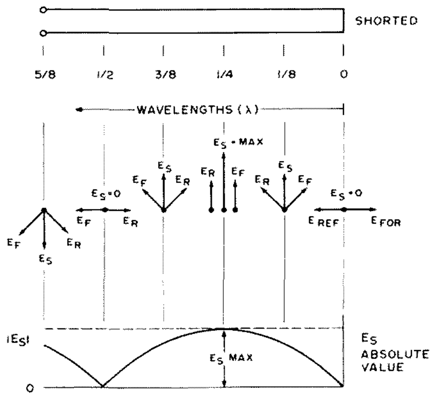


Fig. 2. Diagram of voltage standing waves on transmission line.

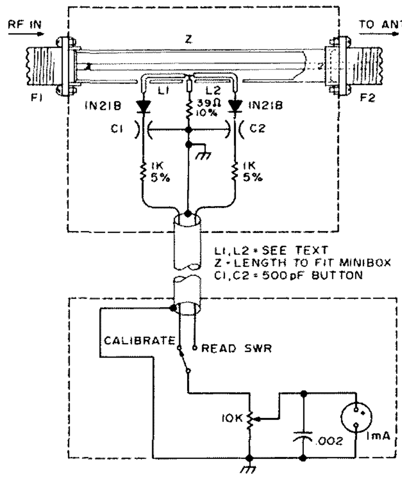

Fig. 3. UHF swr indicator.

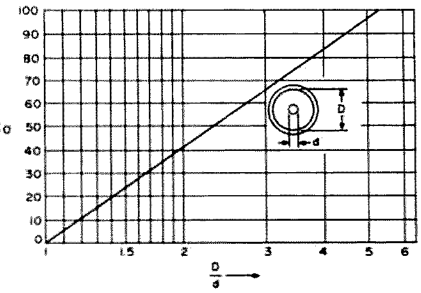

Fig. 4. Ratio of diameters to line impedance.

The frequency limits of the indicator are exceeded when resistor R is not very much lower than distributive element C, and when mutual inductance M is not nearly purely reactive.

Construction Details

A length of copper water pipe is used for the wave sampling section of the transmission line. The use of tubing helps to maintain a constant line impedance, keep the inner field distortion to a minimum, and radiation leakage down. For the center conductor, a #7 or a #3 AWG copper wire will provide a line impedance of 75 or 50 Ohms, respectively. Thin wall model builder's brass tubing of equivalent o.d. was used in constructing the indicator in the article. See Figs. 3 and 4.

To accommodate the sampling loop, drill three 1/8 inch diameter holes ¾ of an inch apart in the copper tubing. Form the insulated sampling loop, and insert the leads through the three holes. Single conductor, tinned, #22 AWG, with thin wall insulated sleeving added, maintains its shape better than stranded wire for the sampling loop. With 3/8 of an inch lead protruding out of each hole, temporarily bend each load so as to make the loop captive. This will help prevent the loop from slipping out of position during the fastening of the end fittings.

Solder the end of the conductor selected for the center lead to a mica-filled SO-239 coaxial fitting. Other types of fittings such as the N or the BNC may be used, but different mechanical arrangements will be required.

The other SO-239 fitting requires modification if no other holes are to be drilled in the outer copper tubing. The modification consists of removing the center pin of the connector. Depending upon the brand and vintage of the connector, some pins are removable by a simple "C" ring clip. Others have a rolled-in ridge for fastening, etc. After the pin has been removed intact, use a drill to establish clearance so that the pin can be freely inserted from the rear side of the connector.

Temporarily slide the copper tubing and loop subassembly over the center conductor with the fitting previously connected to one end. Determine through inspection the proper length the center conductor should be to permit the recently removed center pin to slide into the fitting with the slightly enlarged hole without protruding. The fitting must also butt against the end of the outer copper line. After the proper length has been determined, solder the pin to the center conductor.

Make two rings about 3/8 of an inch long by cutting the ends off a standard copper elbow or coupler section. With all burrs removed, the rings, line, and end fittings are ready for soldering. A 250 Watt gun or iron will speed the assembly.

If the assembly is to fit inside a ready-made minibox, the box selected and the length of the line should be compatible. The box will help keep the sampling loop from being disturbed once positioned. A ¾ inch hole in each end of the box is required, with one hole slightly elongated, so that when the box ends are sprung back slightly, the line assembly may be inserted. The assembly of the rest of the components is straightforward.

To adjust the loops, the line should be inserted into a transmission line, first in one direction and then the other, until the two sets of readings are almost identical (except reversed). Once obtained, place a drop of quick-drying model cement at each of the sampling loop exit leads, without disturbing their placement. Fig. 5 is a typical meter scale.

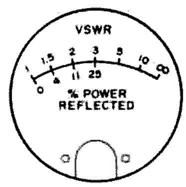

Fig. 5. Typical vswr meter scale.

If the 1N21Bs and resistors have been matched even with the humble ohmmeter, and the parts layout is reasonably symmetrical, little effort should be required to position the pickup loops.

The line and meter may be mounted together in a larger single box if desired. It may also be desirable to use a set of connectors in the interconnecting cable to insert an extension cable when needed to provide remote readings during backyard antenna matching sessions.

The directivity of this indicator, and its ability to discriminate between forward and reflected wave components from 50 MHz to 500 MHz (and maybe even higher), is excellent. The use of type N fittings is recommended for frequencies above 500 megahertz. ■

At Last! A 10m Band Plan

-- requires a CB radio

Here is a plan to use CB rigs on 10 for a worthwhile purpose. If a large number of amateurs go for the idea and equip themselves with a converted CB rig, the result could be a real feather in the ham's cap.

My plan calls for the conversion of the so-called "synthesized" 23 channel rigs to operate with 23 channels on 10. These channels would have uses designated for them as depicted in the accompanying chart. Rag chewing, DX, and routine net operation would be possible with this system, but the real value of it would be seen in a communications emergency.

Where the Citizens Band could be expected to be almost useless in a real emergency due to the immense numbers of undisciplined operators that inhabit its channels, the training and discipline of hams could be expected to yield a very effective local communications system. Because of the fairly low expense involved (compared, say, to 23 channels of coverage on the six or two meter bands), there should be quite a few hams who would provide themselves with the capability to participate in the system.

The rigs themselves are almost ideal for this use; they are small, light, all solid state, and made to operate on 12 to 14 V dc. Most have noise limiter circuits and are very adequate receivers. Conversion for the plan presented here can be accomplished in one evening for around thirty dollars (the cost of six new crystals). To make the conversion, one needs a schematic (usually supplied with the rig), a soldering iron for small work, and the ability to identify and work with basic electronic components. Most hams are so equipped.

The conversion involves changing 6 crystals in the rig. These crystals are in the 37 MHz range; each is to be replaced by a crystal whose frequency is exactly 2 MHz higher. The exact frequencies can be found by consulting the schematic or by looking at the original crystals in the rig. The replacements can be ordered from a manufacturer like International Crystal. Once the changes are made, the receiver and transmitting circuits must be peaked for best sensitivity and power out; my Radio Shack Mini 23 required no other changes. My other CB rig (Royal Sound Model 336) has a similar schematic and should give the same result, though I have not tried it. If you have difficulty, contact another ham who has had some successful experience modifying commercial gear. The detailed conversion of a variety of these rigs is beyond the scope of this article.

Channel	Frequency	Proposed Use
1	28.965	Calling & Distress
2	28.975	Emergency Traffic
3	28.985	Emergency Traffic
4	29.005	Net
5	29.015	Net
6	29.025	Net
7	29.035	Local Rag Chew
8	29.055	Local Rag Chew
9	29.065	Local Rag Chew
10	29.075	Local Rag Chew
11	29.085	Local or DX Rag Chew
12	29.105	Local or DX Rag Chew
13	29.115	Local or DX Rag Chew
14	29.125	Local or DX Rag Chew
15	29.135	Local or DX Rag Chew
16	29.155	Local or DX Rag Chew
17	29.165	Local or DX Rag Chew
18	29.175	Local or DX Rag Chew
19	29.185	Local or DX Rag Chew
20	29.205	DX Only, Short Contact
21	29.215	DX Only, Short Contact
22	29.225	DX Only, Short Contact
23	29.255	DX Only, Short Contact

Table 1. Channels 7 through 19 could be pre-empted for emergency net traffic, should the need arise.

The purpose of this article is to propose a way in which converted CB rigs can be used on one of the ham bands that is apparently under-used and in danger of being lost to amateurs. The idea has potential, but is obviously not completely worked out. If you have objections to this proposal or suggestions on how a better system can be set up, by all means put them on paper and send them to either the editor or myself. Certainly the establishment of such a public service oriented communications system would attract favorable press coverage and the amateur's use of the rf spectrum would be given added justification. ■

Event Timer With Memory

- - double check gravitational laws

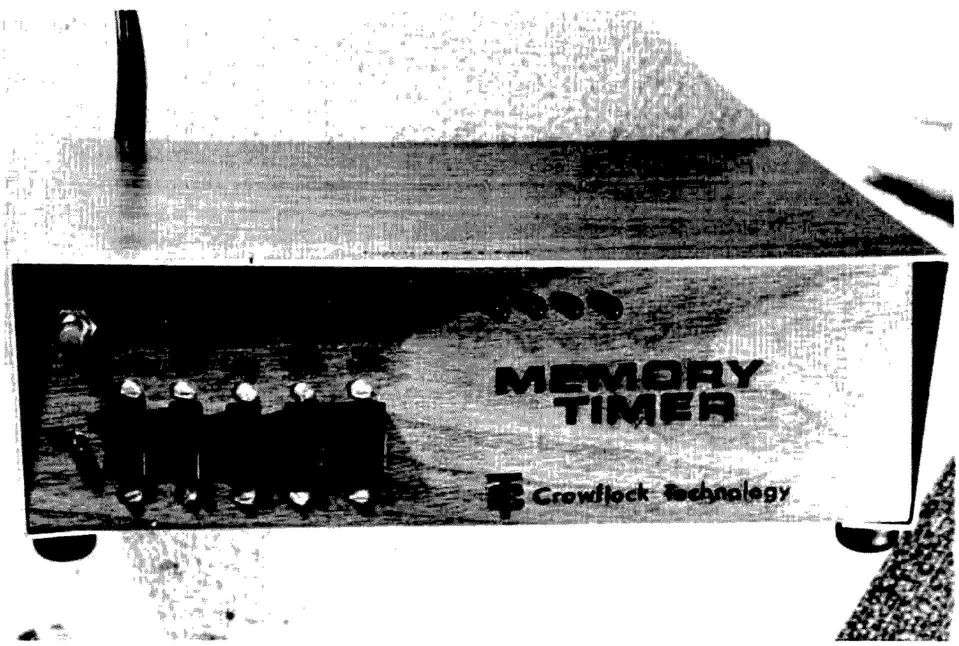
Marshall Jose WA3VPZ
5455 Crowflock Court
Columbia MD 21045

After observing the dubious method used with a crummy timer by my high school's physics teacher to demonstrate the theoretical relationships between distance, speed, acceleration, mass, and time, I decided there must be a better way.

In the true spirit of engineering, I went home and (with time off from homework) worked feverishly on a solution to the above-mentioned farce. "This can be done with digital logic," I grunted, since I am a hopelessly confirmed logic freak. So . . . I whipped out my battered TTL data book and started scrawling those funny looking symbols. The next day I discussed it with the physics teacher – and was commissioned with $45 to build it for the school.

Enough about why – what's it supposed to do? Briefly speaking, the device will time several events with 2 digit resolution using either 1 or 1/10 second accuracy. The time elapsed for an event since initial triggering (t = 0) is both instantly displayed and written into the memory.

At present, an operator must trigger the circuit manually when an event occurs; an automatic triggering option is planned to be added soon. After all the events have occurred (up to 16 times may be stored), the times of the events may be read out at the operator's convenience. (Sound like a stopwatch? It is – in a remote sense.) Also, for those who like blinking lights, a free run mode is available which simply counts off seconds or tenths of seconds on the display.



The metalworking for the front panel was done with a drill and with flat and triangle files.

How Does It Work?

By referring to Fig. 1 and Fig. 2, one sees that simply by pressing RESET, the address counter is preset, the counter chain is cleared, and the clock is disabled. Now, if a storage of "event times" is desired, RUN/READ must be at RUN, FREE RUN/MEM must be at MEM – and don't forget to select the range with the S-S/10 switch. After the device is reset, watch what

happens when the MAN TRIG switch is hit: The S-R FF is set, enabling the clock, and the address counter is incremented to 0000 binary. Meanwhile, that delayed one shot, triggered, just sits back for around a microsecond, waiting for the address counter to ripple through. When the address is stable . . . *bam*! goes a 1 microsecond negative going pulse on the write line, the data shoots in the memory and appears on the readouts a little while later!

Subsequent triggering initiates the above nonsense again, with the exception that the clock is not enabled, simply because it already *was* in the initial triggering, and since then has been toggling away at the decade counter chain.

To read, the reset switch is pressed, and the READ/RUN switch is set to RUN, opening the write line. The times are then read out sequentially from the memory on the display.

In the FREE RUN mode, the write line is disabled again, but this time the memory $\overline{WR}$ pins see the gated clock. In this fashion, the memory is used as an exotic "latch," updating the output of the last two decade counters to the displays one thousand times a second. The address on the memory in this mode is irrelevant.

Construction

The acquisition of components for this project was quite an exercise in penny pinching. Exactly $45 was spent after the parts shopping spree. Note that the parts include the case, transformer, breadboard, ICs, etc. — in other words, everything needed. The spacers used to mount the boards were made from copper tubing — cut, constricted, and tapped for 4-40 screws. The interconnection wire was pulled from an unused multi-conductor cable. Talk about being cheap!

The electronics were constructed on *two* breadboards, a nice master-slave arrangement that minimizes space requirements and (usually) interconnections. The prototype boards were wired literally point to point; that is, wiring was done by soldering the wire directly to the two points concerned — using insulated wire, of course. Upon completion, the undersides of the boards would confuse a rat looking for its nest, but the technique worked anyhow.

Two points that must be stressed are that power and ground buses *must* be heavy gauge wire, and that a .01-.1 microfarad capacitor must be connected with short leads between +5 V and ground every few centimeters along the power bus. The reason is that TTL ICs generally create garbage on their supply lines, and this garbage can confuse ICs further on down the power bus unless effectively bypassed. (A good rule to follow is to assemble the boards and *then* solder the capacitors on, every two ICs or so.) Just another ounce of prevention, folks.

Because the readouts have no limiting resistors and because of other shortcuts, the current demand hovers around 900 mA. The LM309K 5 V regulator runs

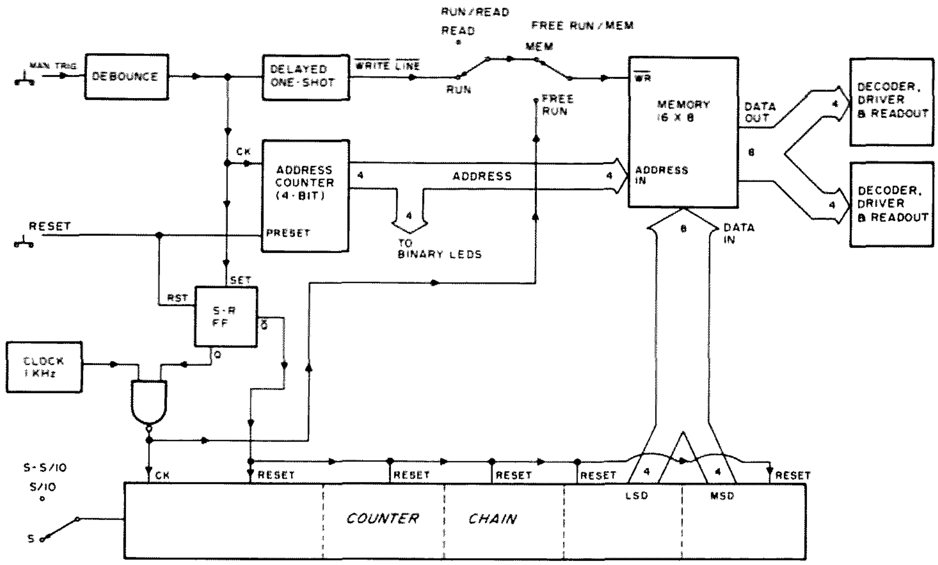


Fig. 1.

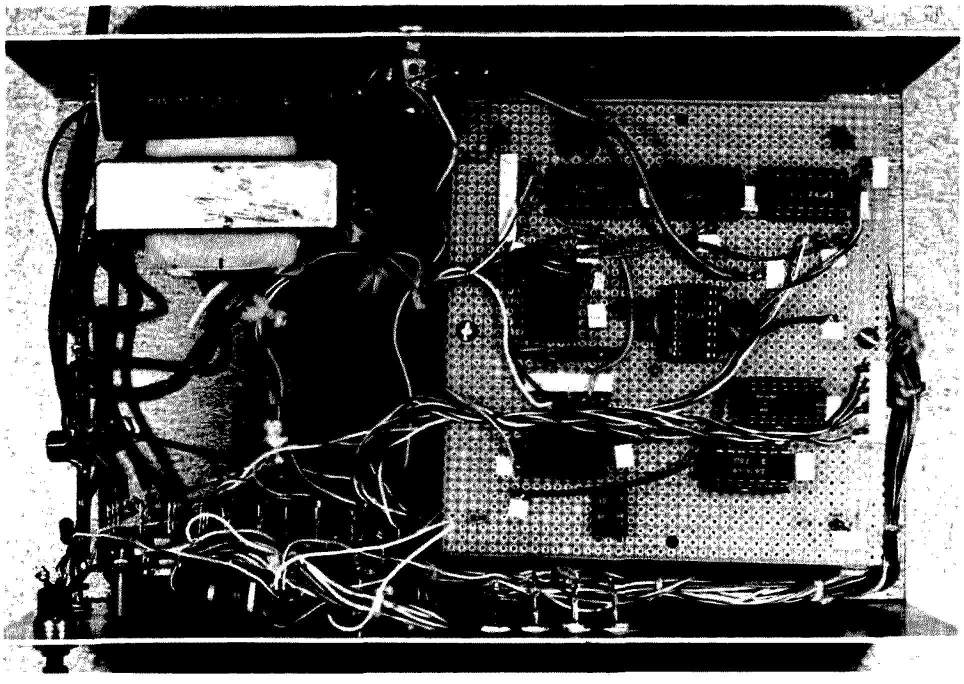

Top view. Quite a mess, but judicious use of color-coded wires simplified debugging enormously.

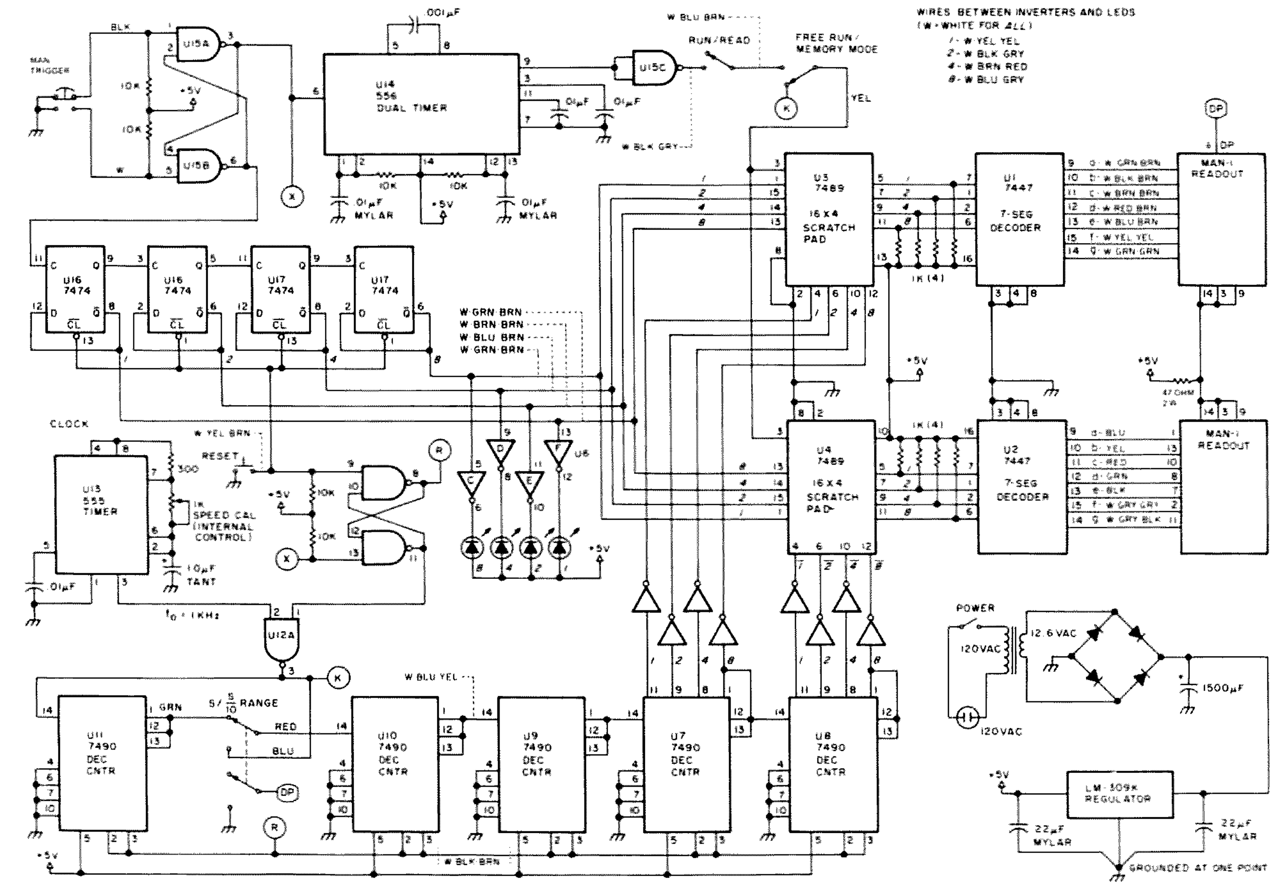

Fig. 2.

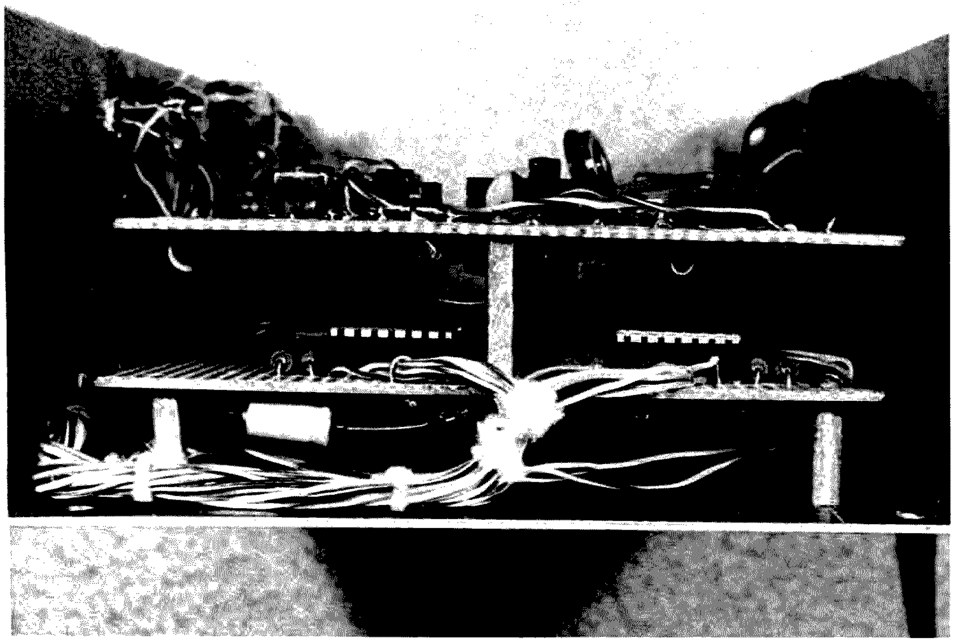
moderately hot, not scorching, but still stays in spec. In fact, the regulator is rather hard to destroy, in that it will shut itself down if too hot.

The debugging equipment consisted of a Dumont 304-H oscilloscope, a cheapie VOM, and a homemade logic probe – truly not an expensive troubleshooting lab.

A final remark about construction: The finished appearance will only be as good as how carefully one builds it; the number of tools in the tool box does not necessarily determine the final appearance.



Side view showing stacking of boards and cable ties made of cotton string.

What's It to Me?

It could not be said what one could possibly use the timer for. However, it obviously has applications other than as a peculiar conversation piece. Not only did it win honorable mention and an SR-11 calculator in the Baltimore Science Fair, but also building it and learning from my mistakes while debugging it was half the fun.

If you build it, I encourage you to add embellishments and change it if you like. Since the circuit itself reflects many features of TTL technology, you'll learn from it. Make it a creative project. ■

Sheet Metal Brake

-- build microwave components

Howard A. Bowman W6QIR
5872 West 77th Place
Los Angeles CA 90045

The ham who builds his own equipment often winds up with one final problem: What kind of a box do I put it in? Small cabinets are not always easy to find, especially when one considers problems of size and appropriate configuration, and the difficulties of "shoe-horning."

The answer is to make one's own cabinets, each custom designed to fit the project it will house. The device to be described in this article won't do everything that the brake in a sheet metal shop will do, but it will suffice for most tasks.

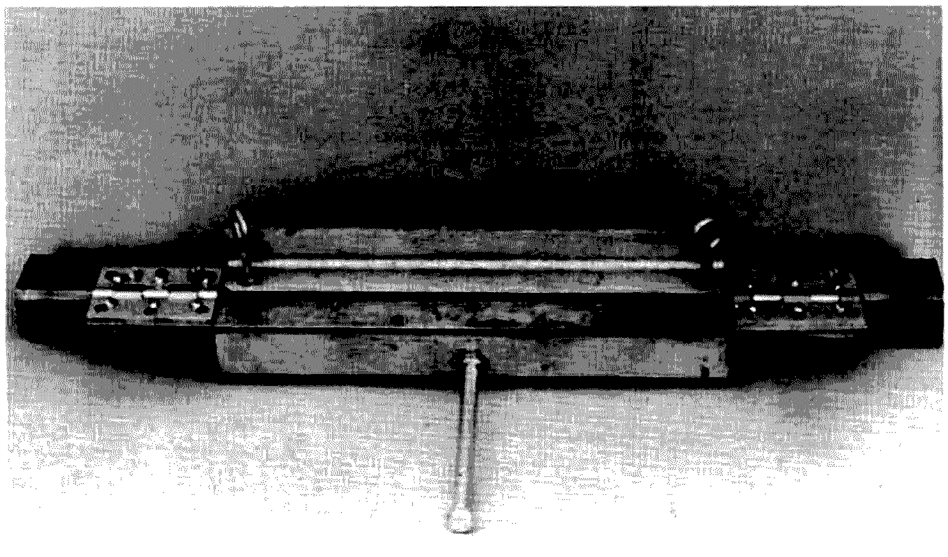
Ours cost less than $10.00 to build, will handle a 10½" bend, and works quite well on the stock normally used for electronics enclosures. It bends aluminum, whether "soft" or "hard," galvanized iron stock, copper, and so forth. It was built with ordinary tools — nothing more exotic than an electric hand drill and 8-32 and ¼-20 taps. We advise the use of a drill press, if you have one, but it is not imperative; further, you can do without the taps if you don't have them.

We built our brake out of 5 feet of 1¼" angle iron, obtained from a local hardware store, a pair of 3" butt hinges, two dozen 8-32 x 3/8" machine screws (half flat head and half round head), a 3/8" x 6" machine bolt, with two nuts and a lock washer to fit, and two ¼-20 x 2½" eye bolts, with nuts. If you do not choose to tap the 8-32 holes, you'll also need lock washers and nuts for the 8-32 machine screws.

Now, before you run down to the hardware store and buy all this stuff, read through the rest of the article. Further along, we'll suggest a couple of possible modifications which, if you can arrange them, may simplify things considerably. Also, they'll mean your purchases will be a bit different.

Let's take a moment now to identify the major parts of our sheet metal brake. We're frank to say that we could find no reference which would tell us the real technical names of these parts, so we made some up and believe they will suffice.

First, there is the *bed*, on which one places the piece of sheet metal to be bent. The work piece is firmly clamped to the bed by means of the *shoe*, which holds the work accurately in place, and provides a radius against which the bend is made. The actual bending is accomplished by means of the *bar*, which is hinged to the bed. To the bar must be attached a device of some kind to provide the leverage necessary to make the bend. That's where our 6" bolt comes in. And, by the way, when you do get to the hardware store, pick up a couple of extra hacksaw blades. You'll need them!



Let's go on the assumption that you are building the brake out of 1¼" angle iron, as we did, and to the same dimensions. And, by the way, it doesn't have to be 1¼" angle; it could be some other size, but probably shouldn't be less than 1". Use what you can conveniently get. In any case, you'll need a piece five feet long. Select it carefully, looking especially at the ends, which often get deformed when a longer piece is cut up. You'll want a piece that is entirely straight and true. When you get it home, cut it into four pieces. Two pieces should be exactly 18" long, one exactly 12" long, and the fourth what's left over — a bit less than 12", because of the saw cuts.

Put the two 18" pieces on a flat surface, back to back, so that they form an inverted "T". Temporarily clamp them together with a couple of small "C" clamps, then turn over the whole assembly and put it in a vise, clamping it securely at the center. Viewed from one end, the two pieces will now form a "T", and the upper surface of the "T" should be absolutely

flat across both pieces of angle.

Now, take a good look at one of the hinges you have bought. Probably each leaf of the hinge will have three countersunk holes in it. However, you're not going to use the hinges as the manufacturer intended. If you did, the hinge pin would not be axial with the juncture between the bed and the bar. To attain this axial condition, simply flop the hinge over, and thereafter ignore the holes made in it by the manufacturer.

One hinge is going to be mounted at each end of the two 18" pieces of angle you are working with. Further, the axis of each hinge pin must be in exact line with the juncture between the two pieces of angle. Line up each hinge carefully, and mark the pieces of angle for cuts which will clear the hinge pin and surrounding metal on each hinge. These cuts, made with a hacksaw, don't have to be super accurate, but they must remove enough metal from the vertex of each piece of angle to allow the center portion of the hinge to drop in, leaving each leaf of the hinge flat against its respective piece of angle (see Fig. 1). In our case, we had to remove about ¼" from the vertex of each piece of angle to a depth of about 3-1/8" from each end.

Once this hacksawing is finished, so is most of the hard labor. Realign the two pieces of angle as before, and put them back in the vise. Put each hinge in its position and, as before, carefully align its pin with the juncture line between bed and bar. Remember also that each hinge goes on upside down,

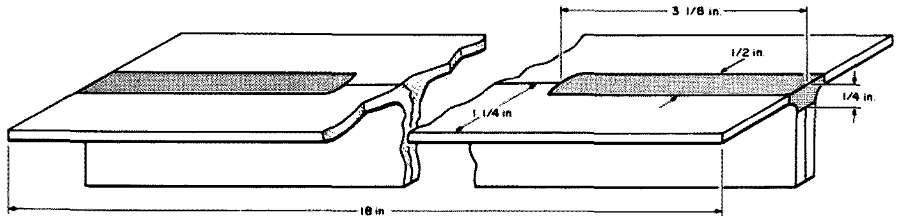


Fig. 1. Enough metal is cut out (shaded areas) to allow room for the hinge pins and surrounding metal.

with its countersunk holes toward the pieces of angle. Moreover, each hinge should now lie flat, with the hinge pin and surrounding metal in the slot you have just hacksawed out.

Securely clamp each hinge in place and center punch on each leaf of each hinge three locations for your 8-32 round head mounting screws. These locations should be relatively close to the hinge pins, yet far enough away to clear the screw heads, and the nuts, if you intend to use them. While the hinges are still clamped, drill out the three holes with a No. 29 drill, which will accept an 8-32 tap. When all holes are drilled, remove the hinges and redrill the holes in the hinges only with a No. 18 drill, which will clear the 8-32 machine screws. If you're going to use lock washers and nuts, you can drill with the No. 18 to begin with. If you are using the drill-and-tap method, with the hinges off, you can now tap the holes in the bed and in the bar, and then remount the hinges. Fig. 3 shows how the hinges mount.

Next job is to mount the shoe. It is positioned atop the bed, as shown in Figs. 2 and 3, and is a 12" piece of angle. Carefully align one edge of the shoe with the juncture of the bed and bar, and clamp it in place. Then, about ½" in from each end, drill through both the shoe and the bed with a No. 7 drill, which will accept a ¼-20 tap. Remove the shoe and redrill the two holes in it to clear the ¼" x 2¼" eyebolts which will be used here as clamps. Use your ¼-20 tap on the two holes in the bed. Run a nut about ½" on each eyebolt before installing it, and you will find that the combination will clamp the shoe firmly to the bed.

Again, if you are not going to tap the holes in the bed, you will find it necessary to devise an alternate method of clamping. Later on you will see that we attached the brake to a piece of 2" x 2" lumber to afford a means of holding the brake in a vise or clamping it to the workbench. From this, one method of providing a clamp for the shoe that suggests itself would be to run long quarter-inch bolts through the wood mount, with nuts between the mount and the brake bed, but with the bolts extending through both bed and shoe. Then wing nuts might be used for clamping.

The final task is to provide some leverage for making the actual bend in a piece of sheet metal. We accomplished this by mounting the last piece of angle – the one slightly less than 12" long – to the bar. It was clamped to the bar and seven No. 29 holes were drilled in a staggered fashion across the length of the angle. The clamps were removed and the holes in this last piece were tapped with an 8-32 tap. Holes in the bar were then redrilled to pass the 8032 machine screws, and countersunk so that the flat head screws would be flush with the surface of the bar.

If any screw heads are slightly cocked, they should be filed flush. If problems still remain, all is not lost. When a piece of metal is to be bent, a thin sheet of paper or plastic slipped between the work piece and the surface of the bar will protect it.

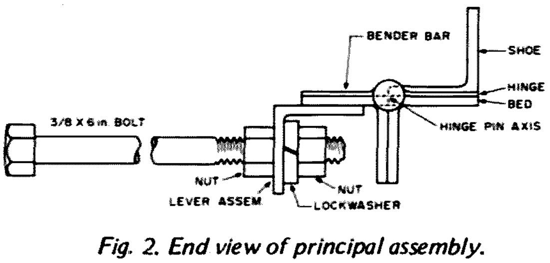

Fig. 2. End view of principal assembly.

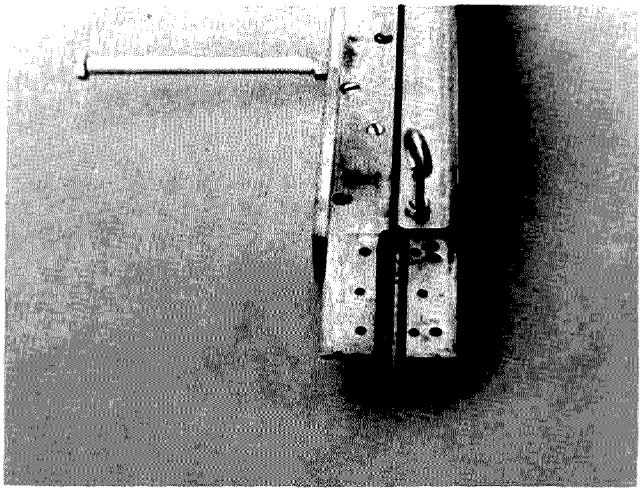

Photo shows how ends of pieces of angle iron are hacksawed out to provide mounting for hinges.

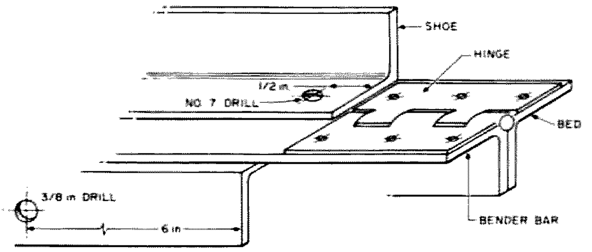

Fig. 3. Hinge positioning and location of bending lever.

Here again, if the builder does not wish to tap the holes for the 8-32 mounting screws, he may drill the holes to clear them and use lock washers and nuts on the under side. If this is done, precaution should be taken to drill the holes in positions so that there is room for the nuts on the underside of the angle.

The final step is to add the 3/8" x 6" machine bolt to the outer face of the piece of angle we have just attached to the bar. Simply find the center of the outer face of that piece of angle, and drill a 3/8" hole through it. Run a nut on the machine bolt about ½", put the end of the bolt through the 3/8" hole, and secure it on the inside with a lock washer and nut.

It is at this point that a couple of attractive alternatives suggest themselves. Note that when this last piece of angle has been attached to the bar, these two pieces form an inverted "U", as shown in Fig. 2. Since the means of attachment is unimportant, so long as it is sturdy, the two might be welded together, if you have access to welding equipment. Note, however, that if any portion of the welding bead extends above the face of the bar, it will have to be ground or filed off, to prevent marring the work.

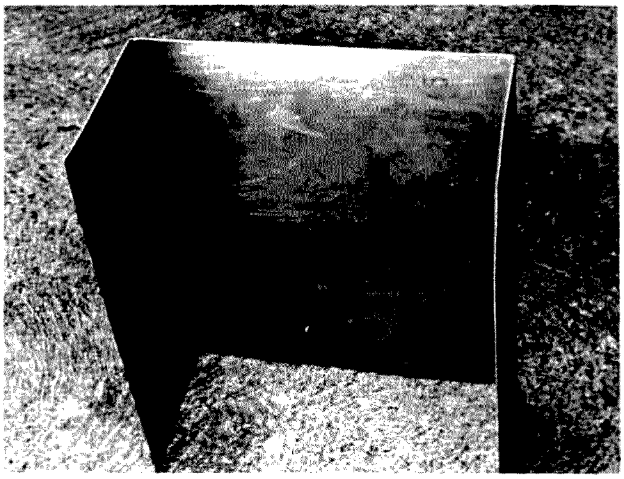

Photo shows half of a cabinet produced with the brake described.

Even more attractive is the idea of substituting a piece of channel for the bar, and perhaps even for the bed. This would obviate the use of screws, welding, or any other means of attachment.

As indicated earlier, some means must be devised to hold the brake securely while it is in use. We simply used wood screws to attach the bed to a piece of 2" x 2" lumber about two feet long. When not in use, the brake may be stored in an obscure corner. To use it, we simply clamp the 2" x 2" to the bench with a pair of large "C" clamps, or hold it in a vise. ■

The Easy Ammeter

- - current news

Have you ever wanted to measure the current flow of a particular transistorized device that is sitting on your workbench?

If you are like most of us, you are basically lazy and sometimes bypass this important step, due to the inconvenience of breaking the power lead and then having to resolder it again.

Here's a really easy way to measure current flow. Since most transistorized gear is powered from a battery pack of some sort, all you have to do is stick a piece of double-sided printed circuit board between any two batteries, as shown in the diagram.

Touch the two meter leads to each side of the PC board and there you have it — instant current reading without cutting and soldering any wires. ■

Try a Conduit Vertical

- - low angles are great for DX

Ever since my Novice days, not all that many years ago, I've been spending most of my time on the air in search of that increasingly elusive critter known as "DX". However, with the serious decline in the sunspot cycle and sometimes total lack of DX on the air during this past year, I found I was spending more time in good old-fashioned rag chews. As a result of working some states on bands I'd never worked them on before, I became interested in trying to achieve 5 Band Worked All States.

The first problem I had was in getting back on the 80 meter band. After upgrading from Novice, I had sold off my 18 AVQ allband vertical in favor of a beam with which I set out to chase DX. Having nothing really suitable enough from which to string a good dipole antenna, I decided on a ground mounted vertical. Now, the handbooks are replete with vertical antenna designs, but few ever suggest means for building an unguyed, free-standing configuration by using easily obtainable materials. I recalled that when I had first gotten on the air as a Novice, I built myself a home brew rotatable dipole for 15 meters. You may recall this old *ARRL Handbook* design, which utilizes two ten foot lengths of 1/2 inch thin wall electrical conduit mounted on a short length of 2" x 2" redwood with standoff insulators. I felt this same type of construction should work in home brewing a vertical.

I found that thin wall electrical conduit of 1", 3/4", and 1/2" would telescope into one another, but not with a sliding fit. By cutting a couple of two inch lengths off the ends of the 3/4" section and slitting them lengthwise, I was able to expand these small sections to fit around the end of the remaining length of 3/4" conduit as shims, spaced about 8" from one another (see Fig. 1). This shimmed end, with the help of a little electrically conductive lubricant, was easily forced into one end of the 1" conduit.

To insure electrical continuity and to prevent slipping of the two sections, I drilled radial holes through the two joined sections at the shim locations and inserted heavy pan head sheet metal screws.

The same procedure was followed in telescoping the 1/2" conduit into the other end of the 3/4" conduit. To prevent corrosion at the joints, it is suggested that they be sealed at their ends with a bead of automotive grommet sealant or vinyl electrical tape.

When the three lengths of conduit were fastened together, I prepared a vertical support using a 4 foot length of 2" x 4" redwood. Four 2" standoff insulators were mounted on the redwood support, and equally spaced from one another, beginning at approximately one foot from one end. A fifth standoff insulator, which may be of smaller size, is attached at the free end. The one inch conduit section is then fastened to the ends of the four insulators using loops of 3/4" perforated metal stripping which is available in most hardware stores (see Fig. 2). To prevent the conduit from sliding down through the loops when the finished antenna is elevated, pan head screws are inserted through holes in the loops and fastened to the bottom conduit section.

Since the finished length of the three telescoped sections of conduit is approximately 27 feet 4 inches, it will be necessary to add an adjustable base loading coil to enable the finished antenna to resonate properly at various frequencies. One end of this coil should be fastened to the bottom end of the one inch conduit section, and the other end is fastened to the unused standoff insulator (see Fig. 3). An SO-239 coax fitting should be mounted on the lower end of the redwood support, near the end of the loading coil fastened to the standoff insulator, by means

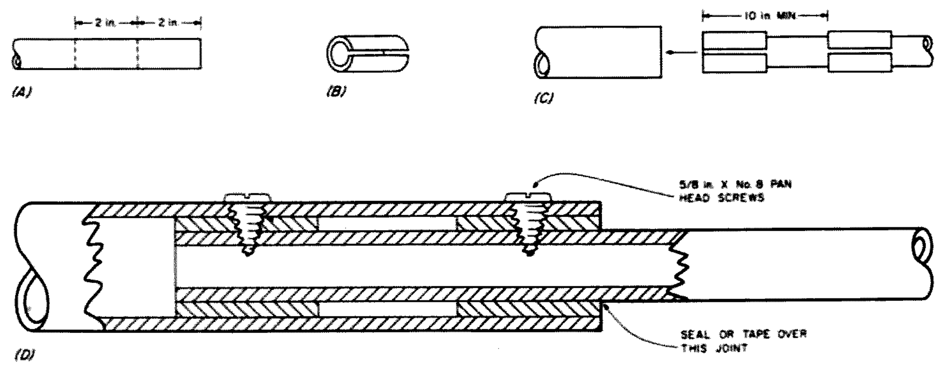

Fig. 1.

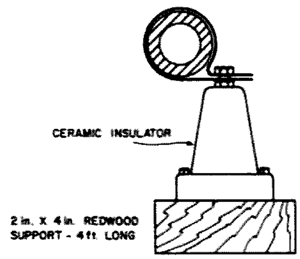

Fig. 2.

of a right angle metal bracket. A short length of wire, to serve as a coil tap, is run from the center conductor of the SO-239 coax fitting to the desired resonance spot on the loading coil, and soldered at each end. The tap location on the loading coil is a fit-and-try operation after the antenna is erected and placed on the air, the object being to find the tap location which gives the lowest swr at the desired operating frequency.

If you intend to use the antenna for more than one operating frequency, you will need to have a small clamp connection on the tap wire which will allow you to move its location on the loading coil. If your station includes a transmatch or similar matching device, you may eliminate the loading coil and simply run your tap wire directly from the coax fitting to the lower end of the one inch conduit. Loading of the antenna is accomplished by simply tuning the transmatch for lowest swr.

Having completed assembly of the antenna and its support, it is a simple matter to fasten the redwood support with U-bolts to a pipe of at least 1-1/2" diameter driven into the ground a minimum of 4 feet. Get some help in elevating the antenna and mounting it on the pipe, however, because it is not a lightweight antenna, and you will very likely break the ceramic standoff insulators if it falls to the ground.

As with any vertical antenna, a network of radials should be securely connected to the ground side of the SO-239 coax fitting at the base of the antenna. A few eight foot ground rods, also connected to this ground side of the coax fitting, should be driven into the ground equally spaced from one another on a 12" radius from the support pipe.

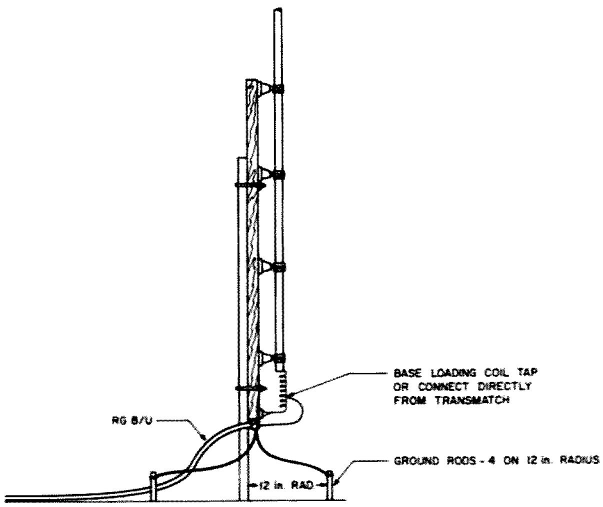

Fig. 3.

This antenna has been in operation at our home QTH for nearly a year and has stood up well to windstorms with no damage. We have managed to obtain many of the QSLs needed for 5 BWAS on 40 and 80 meters using this antenna, and it has also operated well on 40 and 80 meter DX in the most recent CQ WWDX contest. It has also performed admirably in acquiring those states needed for the Bicentennial Worked All States Award.

If you want a good antenna for 80 and 40 (and other bands for that matter), the electrical conduit vertical is a cheap and effective way to go, especially if you don't have the room, or inclination, to string up one or more dipoles. ■

The IC-PC Connection

-- convenient and cheap

Having become enveloped in the digital mania, and breadboarding many circuits, I came across a problem that I'm sure many have stumbled across. As the projects became more complex, I found the wires coming off the perfboard it was constructed on more numerous. This becomes a big headache when modifying the circuit and having to unsolder, then resolder, all those darn wires. A cheap, but easy, connector was the only way. Not wanting to spend all my time hunting around for the right type of connectors, I decided to gamble and sent off for some ordinary "Soldertail Standard" IC sockets hoping they would be easy to modify. Luckily they worked out quite well, and I'm surprised no one has thought of it before. Since from 8 to 24 pin (and greater) IC sockets are easy to latch on to, the quantity of wires coming off the board presents no problem. Here's how it's done.

First, that socket pops apart by snapping off the cap or top section, leaving you the base or bottom section. Those things you're picking off the floor are the pins. The pin holes in the cap need to be drilled out wide enough to accommodate the width of the wire, and the pins have to have the formed spring contacts bent apart so the wire can slip down between them. The pins are a little difficult to work with, so be patient, and whatever you do don't do this over a shag rug because the only way to find a lost pin is the hard way, barefoot and unexpected.

To put it together, just thread the wire(s) through the cap, strip off 1/16" of insulation and solder to the pin. Once all the other pins are completed, slide the pins back into the base and slide the cap down until it snaps in place. Fini! When using ribbon cable, the end product looks good enough to use these connectors on the finished project when laid out on etched circuit board. Since "Soldertail Standard" sockets when used as the male connector won't plug into a "Low Profile" socket, you will have to use the "Soldertail Standard" for both male and female. ■

An 82S23 PROM Programmer!

-- now build those projects using one!

The 82S23 is merely the Schottky version of the 8223 programmable read only memory which has become popular in home-built amateur radio equipment. A year ago the 8223 was plentiful on the surplus market. Now, however, the supply is drying up because it is no longer manufactured (at least not by Signetics Corporation). Being an experimenter, I bought the Schottky type PROMs when they were offered at the same price as the 8223. I was in trouble immediately. My programmer was the usual simple type the circuit of which has been published in several hobby magazines. Even by using a fusing potential of 15 volts and no current limiting, I could not blow the links.

A Solution

A chance acquisition of the publication, *Signetics Bipolar Memories* (current issue, no date), led to a solution to my problem. Among other things, the manual shows a circuit for programming the 82S23 and the 82S123 (3-state output). Evidently a short rise time and a controlled amount of fusing current are required to completely and permanently fuse the links in a Schottky PROM. Five 1-shots are used to automatically pulse three parameters of the PROM. A hurry-up version of the circuit was put together and it works just fine. No construction details are included in the manual, so a potential builder might benefit from my labors.

The Schottky programmer is complicated and costly when compared with the simpler programmer usually used for home programming of the 8223 (e.g., *RTTY Journal*, February, 1976, page 9). Also, the programmer will not be used often, so the average ham will look to avoid buying parts. Be sure to check all switches to be used in the address and bit positions. Old toggle switches sometimes hang up and toggle later. This could ruin a PROM. I lost one that way even though I had checked and doubled-checked the switch.

Remember that there are two configurations for double-throw toggle switches (something that even the catalogs don't always mention). Some switches have the "ON" position coincident with the toggle handle, and in others the handle is opposite the "ON" position. Wiring will be made more difficult, but be sure to install the switches so the positions of the toggle handles mean the same thing. A quad NAND gate and two 2N697 transistors may be used instead of the dual peripheral driver. A resistor of about 470 Ohms should be placed between the outputs of the gates and the transistor bases. Be careful in using a lower value of dropping resistor to get more brilliance if you substitute LEDs; the DUT (device under test) may have to sink too much current. An SE 9300 family transistor may be substituted for the MJE 1103 (it must be a Darlington type). Be sure to provide heat sinking for all three voltage regulators. The zener diode clamp at VR3 will overheat and fail if pin 3 of the regulator is left ungrounded for an extended period. An additional 1-shot and LED may be used to see if the 1-shots in the circuit are functioning. See page 84 of *Radio Electronics Magazine* for June, 1976.

Referring to page 26 of the Signetics manual, the timing diagram below the circuit diagram indicates the action initiated by the five 1-shots. However, more information is needed to fully explain the operation. See Table 1. CR1-CR3 are the diodes in the base circuit of Q2 (2N2222). Q1 controls the 15 volt input power to VR2. Q3 and Q4 are the substituted 2N697 transistors. Q3 controls output of

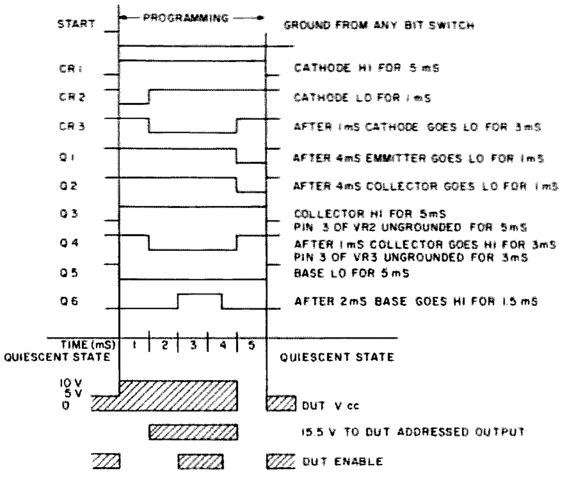

Table 1. Programmer timing diagram.

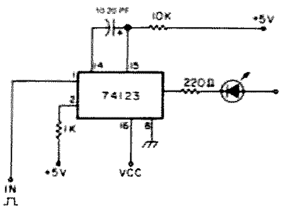
Fig. 1. Pulse catcher, Radio Electronics Magazine, *June, 1976.*



VR2, 5 volts for DUT verification and 10 volts during most of the programming cycle. VR2 output is forced to zero, however, near the end of the cycle, by action of Q1. Q4 switches output of VR3 from zero to 15.5 volts for fusing the links. Q5 and Q6 are in the NOR gate which enables the DUT. U4 is the substituted quad NAND gate.

With the simpler programmer, an address is selected and about 12.5 volts is applied for (hopefully) ½ second. In the Schottky version of the programmer, fusing operation is as follows:

1. DUT disabled;
2. Vcc raised to 10 volts for 4 ms;
3. After 1 ms (after start of programming), addressed output is raised to 15.5 volts for 3 ms;
4. After 2 ms DUT is enabled for 1.5 ms;
5. Both Vcc and fusing voltages go to zero for 1 ms.

At the end of the 5 ms programming period, conditions revert to their quiescent state (5 volts at Vcc and DUT enabled).

Inasmuch as these memories are irreversibly programmed, the unit should be checked each time it is used (DUT not installed).

U4 (7400) Not In Socket

1. All LEDs lighted.
2. Check 10 volts at DUT socket pin 16.
3. Check logic LO at DUT socket pin 15.
4. Check 15.5 volts at DUT socket pins 1-9 when BIT switches are in the N.O. position and 2 volts when in the N.C. position.

U4 In Socket

1. All LEDs lighted.
2. Check 5 volts at DUT socket pin 16.
3. Check 0 volts at DUT socket pins 1-9 when BIT switches are in the N.O. position and 5 volts in the N.C. position.
4. Logic LO at DUT socket pin 15.
5. Check 5 volts at DUT pins 10-13 when ADDRESS switches are in the "1" position and 0 volts when they are in the "0" position.

It is well to check that the DUT has not already been programmed or has missing bits for some other reason. After checkout of the unit as above, use the following procedure to verify the status of the DUT.

1. Set ADDRESS switches to the "0" position.

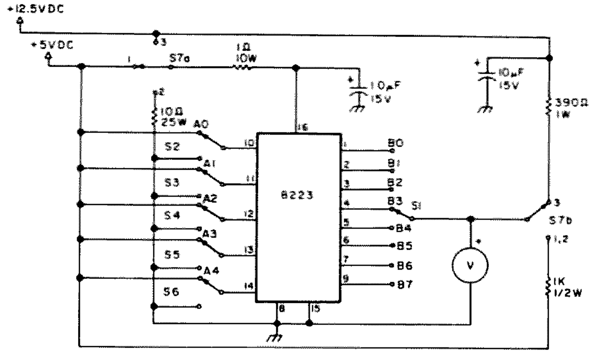


Fig. 2. "Simpler" programmer circuit.

2. Set BIT switches to the N.C. position.
3. Insert DUT.
4. Any LEDs that are lighted indicate blown links at address 00000.
5. Check other addresses as appropriate by setting the ADDRESS switches. (Do Not Touch The Bit Switches.)

Operation

Programming the DUT is pure simplicity, but attention to detail is enforced just as in any programming.

1. Set ADDRESS switches.
2. Actuate required BIT switch to blow the link.
3. The LED will light.
4. Actuate any remaining switch for logic "1" at that address.
5. Set next address and continue.

Conclusion

This programmer for Schottky PROMs works fine for the non-Schottky 8223. Industrial users of PROMs are not always so lucky with their exotic, automatic programmers. One $8,000 machine will program the 82S23 but not the 8223. There are substitutes for the 8223 and 82S23 but caution is advised; there are subtle differences. For instance, in some units, the outputs are programmed from "1" to "0" instead of from "0" to "1" as in the 8223 and 82S23.

A review of other programmer circuits in the Signetics manual makes it apparent that a "universal" programmer could be built to program at least all of the Signetics PROMs of this type. A universal programmer would make an excellent club project. In addition to automatic identifiers for repeaters and RTTY, the impact of microprocessors is beginning to be felt by almost everyone. As more "software" becomes available, operators will want some of their short routines stored in "firmware." ■

Practical P.S. Design

- - do it right this time

One of the most common types of articles published is that on the building of a power supply. Usually the power supply will be a 12-14 volt unit which is capable of providing 3 Amps or so, which will power most solid state VHF transceivers. What is apparent from reading these articles is that most hams do not really understand power supply design, and, because of this misunderstanding, will waste parts and end up with a design which is not doing what the builder wants. This article will try to reveal some of the more common pitfalls, and present a simple design which will provide good, safe, general service.

The first part of any power supply to look at is the power transformer, diode rectifier, and filter combination. We want to get a transformer with a rating of greater then 12 volts, since we want a regulated output of 12-14 volts. It would be best to get a transformer of about 15 volts rms rating, but this is not a very common transformer. A transformer of a higher voltage rating (20 volts or so) is OK, but this would mean the regulator would have to dissipate a lot of heat, which wastes power.

About the best we can do is get a transformer which will deliver a solid 12.6 volts at 3 Amps. Some of the less expensive transformers will drop several volts at full current — try to avoid these. You may wonder how to get a regulated 12.6 volts from a 12.6 volt transformer. The trick is in the rating of the transformer in rms voltage. Since ac voltage is constantly changing in value, at any given instant its absolute voltage may be anything from zero to the peak value. Because of this, ac voltage is given based on how much work it will do. 12.6 volts ac rms will do the same work (heating a resistor) as 12.6 volts dc; however, the peak ac voltage is 1.414 times the rms voltage. A simple rule of thumb is, "split rms in two, and add this figure to the rms." This would say, 12 volts divided by 2 equals 6 — add this to 12 for 18 volts peak.

This method gives a ballpark figure which is close enough to work with. Using this figure of 18 volts, I know I want rectifier diodes which have a reverse breakdown rating of greater then 18 volts, and can handle current in excess of 3 Amps. This part is easy, since most power rectifier diodes handle at least 25 volts. In selecting the diodes, it is best to allow a margin of safety to allow for current surges and voltage spikes. The turn-on current surge could damage the diodes when the power supply is first turned on, but the resistance of the transformer's winding is usually enough to protect the diodes (which are able to handle currents on the order of 50 times the diode rating) for a very short period of time. In this case, a 5 Amp, 60 volt bridge would be good.

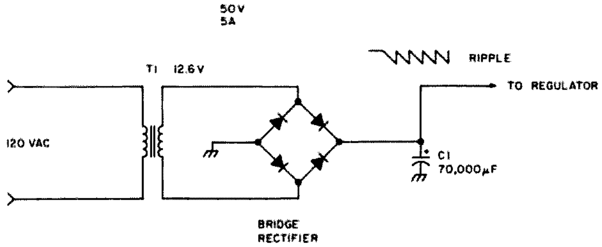

Fig. 1.

Now comes the filter. There are several types of filters, but we will only go into the most common, which is the capacitive input type. This filter is simply a capacitor across the output of the rectifier. This capacitor will, under no load conditions, charge to the peak value of the voltage from the transformer, or, in this example, to about 18 volts. The capacitor must have a voltage rating of at least 18 volts (preferably 20 volts). One of the major pitfalls is encountered in the selection of this capacitor. It does not need to be so large as to give pure dc at full load. Its value should only be large enough to prevent the voltage drop between charging pulses from the rectifier from dropping below the point where the regulator falls out of regulation. Most regulators will require no more then 3 volts across the series pass transistor to maintain regulation. That being the case, we may have 18 V-12 V plus 3 V for 15 volts minimum before dropping out of regulation. Fifteen volts minimum from 18 volts maximum gives a maximum of 3 volts allowable ripple. To have a larger capacitor and less ripple serves no useful purpose and wastes space with the larger capacitor. To figure this capacitor value, figure the regulator impedance as seen from the filter capacitor under full load: 3 Amps (full load), 18 volts (peak charge), divide (E/I equals R) 18 V by 3 A, giving us 6 Ohms.

A simple review reminds us that T equals RC, or resistance (in Ohms) times capacitance (in farads) equals time (in seconds) for a 63% charge or discharge of a capacitor. If we draw the discharge curve of a capacitor and label the top as the peak 18 volts, and the 63% discharge point (6.6 V), we can now see what percentage of the discharge time it takes for the capacitor voltage to drop below 15 volts (regulated output voltage plus 3 volts). In this case I will refer to the *Amateur Handbook*, where there is a printed graph which shows time constant vs. percent of discharge. The 3 V allowable discharge is about 16% of the charge which becomes, on the graph, 84% charge at about .2 time constant. As you can see, a greater peak voltage would allow more ripple to play with, and hence a smaller filter capacitor. In this case it will require 5 (1/.2) time constants to not drop below 84% of charge between charging pulses from the rectifier. The power supply will be running from 60 Hz ac and the full wave rectifier will put out charge pulses at a 120 Hz rate, or one pulse

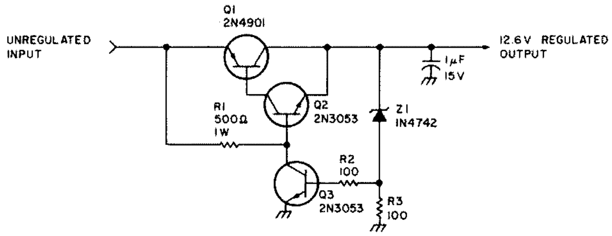

Fig. 2.

every 8-1/3 ms. Five times this figure gives a required time constant of .416 seconds. Now we know that R equals 6 Ohms and T equals .0416 seconds, and that T/R or .0416/6 equals .0069333 farads or 6,933 uF. This says that with the transformer and current requirements given, this power supply needs 7,000 uF for filtering.

After what has just been discussed, to remain pure I must mention that the regulator does not remain a constant 6 Ohms. This is because the regulator adjusts to maintain regulation and as such is more of a constant current sink. This being the case, the discharge curve will be a straight line (linear) until the regulator drops out of regulation. When dealing with the upper part of the discharge curve, as we are, the difference is unimportant, and falls into the area of slop to be covered by the "margin" factor.

Now for the regulator, another pitfall. Nowadays the easiest thing to do is use an IC regulator with a external pass transistor. For the sake of this article, the IC route won't be followed, since we would not learn much about how it works. Refer to Fig. 2 for the regulator we will be using. The series pass transistor will be selected mostly by the current capability. We want a PNP that can pass 3 Amps and dissipate 15 Watts or so. The dissipation required is determined by the voltage drop across the series pass transistor at full load. Since at that point the filter cap will also have maximum ripple giving lower average power, we can add a safety margin by maintaining the full voltage differential for our calculations. 18 V-12.6 V equals 5.4 V. 5.4 V x 3 A equals 16.2 Watts worst case dissipation. A small heat sink and almost any power transistor can handle that. Let me inject that to parallel series pass transistors is a total waste, in this case, as almost any power transistor can handle this power level.

To point out a common mistake, you cannot just parallel two transistors. Refer to Fig. 3(a). It won't work, although it will appear to. The base emitter junction is electrically a diode with a conduction voltage of about .6 volts for a silicon transistor, and about .2 volts for a germanium transistor. It may be assumed that no two junctions are exactly alike, and because of this, one will conduct before the other, not allowing the base voltage to rise further, to the conduction point of the second transistor. Thus it will not turn on unless the first transistor is damaged.

Two transistors can be paralleled if a small resistor is placed in the emitter circuit of each transistor. This allows a small voltage change in the base emitter circuit, with the current through the transistor. If one transistor conducts more than the other, the voltage builds across the junction of the conducting transistor, causing the other transistor to turn on harder, striking a balance. Without this emitter balancing resistor, the second transistor is wasted. Refer to Fig. 3(b).

Now to pick a series pass transistor ... PNP ... 20 Watt ... inexpensive, and some gain. As you can see, almost any PNP power transistor will do, but let's pick a 2N4901. This transistor is rated for 40 V, 85 W, and costs about $1.75 from Motorola. The gain for this device is a minimum of 25, which means that at 3 Amps we must be able to supply a worst case base current of 120 mA. The best way to do this is to use another transistor which will amplify a much smaller current. For the driver transistor, we will pick a 2N3053, which has a breakdown voltage of 40 volts and a minimum gain of 25. Refering to Fig. 2, we will wire Q1 and Q2 together as shown, in a compound Darlington configuration.

Now to figure the value of resistor R1, which must supply enough base drive to provide the worst case drive to Q2. Since Q2 must drive Q1 with a maximum of 120 mA (output current divided by gain of Q1), we will drive that 120 mA by the gain of Q2 to get a rounded off 5 mA drive requirement for Q2. At 3 Amps output, the filter capacitor voltage will be dipping to as low as 15 volts, so with a worst case low input voltage of 15 volts and division by .005 Amps, we find that the resistor value should be about 500 Ohms. To figure the power dissipation of the resistor, we must take the maximum voltage across it, which occurs at no load, with maximum charge on the filter capacitor. We know from earlier that the no load voltage will be about 18 volts. The base of Q2 will always stay within about 1/2 volt of the output voltage, so we now know that the worst case voltage across R1 will be about 6 volts. Again, using Ohm's Law, we take the 500 Ohms and divide into the 6 volts to our current at 120 mA. I times E equals P, or .12 Amp times 6 volts equals .72 Watts. A one Watt resistor would be in order here.

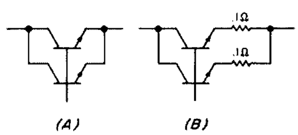

Fig. 3.

Now for the feedback loop which makes this into a regulator. Z1 is a 1N4742, 1 Watt, 12 volt zener diode. It is connected as shown with R3, whose only purpose is to sink any leakage the diode might have and to assure that the diode operates in its proper current range. The value is not critical and the 100 Ohms shown will allow about 6 mA to flow through the diode before regulation takes place. The purpose of R2 is only to protect Q3 against a sudden current surge that might damage the base junction before the regulator can respond. With Q3 installed as shown (almost any NPN transistor will work), any current in excess of the 6 mA designed to flow through Z1 will turn on Q3, causing it to steal base current from Q2 until the output voltage reaches the cutoff point of Z1. The circuit won't allow the output to go above 12.6 volts (the extra .6 volts comes from the base junction of Q3), and if it tries to go below 12.6 volts, Q1 and Q2 drive harder and won't allow that. So what we have is a rock solid 12.6 volts.

Now for the final pitfall. C2 is not a filter capacitor. To try and filter at this point will waste a big capacitor. C2 should only be a small capacitor to *bypass* any high frequency noise which might appear at this point. A 1 uF will do just fine.

In conclusion, while this article was intended to show how to design a simple power supply and avoid some of the common pitfalls, if built it will provide a solid, pure 12.6 volts at a continuous 3 Amps. In fact, since all was figured on worst cases, it will supply in excess of 3 Amps and not feel much strain. Current limiting and overvoltage protection could be added with little effort. ■

Yaesu FRG-7 Impressions

-- take note, SWL fans!

Manufacturers' specifications look very tempting. They can seem to provide the optimum solution to your radio receiving problems. And, remarkably enough, usually the specifications are accurate.

Dry figures, however, don't tell the story as well as hands-on intimacy. Unfortunately, it's seldom that one gets to take a prospective purchase home for a familiarization period before plunking down a wad of that green stuff. And once that green stuff has changed hands, often it's difficult to whistle it back!

That brings us to the subject of this article, one man's experience with a receiver that's new to the American market. Perhaps these experiences will assist you in making a decision as to whether the FRG-7 is your cup of tea.

First impressions are strong, often lasting. The first impression presented by the FRG-7, as it is being unwrapped from its heavy plastic cocoon, is that of exquisite neatness. It's packaged complete with every type of connector you could possibly need and even a hank of antenna for a random wire (called "long-wire" by those who don't know their nomenclature) antenna for reception of signals your dipole might not pick up too well. Look at the front, and you'll be impressed by the orderly array of controls. Nothing is "Mickey Mouse." Yaesu has been making high quality transceivers too long to half-mast its standards!

The instruction book, unlike that of many imports, is written by a person familiar with the English language. It's not quite as complete in detail as one might like, and is really a far cry from those put out by the E. F. Johnson Company before it deserted amateur radio for the dazzling dollars of CB. It's not too skimpy, though, and contains a pull-out diagram that can be read easily without the aid of a magnifying glass! From the list of recommended test equipment for servicing, one gets the impression that Yaesu would like for owners to keep their hands out of the receiver's innards. That's probably founded on past experiences with other solid state products!

It takes only a few minutes to absorb the simple operating procedures. You set the controls for the frequency band desired . . . and snap on a thumb-sized toggle switch. And, as an aside, unlike most Japanese-manufactured radio receivers, that toggle switch is in the primary of the power transformer, not in the "B+" lead!

I hope you do your initial listening either on AM phone or on CW. It works quite acceptably on both of those. But if your first try is on SSB, you may conclude that you made a regrettable mistake in judgment when you bought a Yaesu FRG-7! Let's face it. The combination of 1000 kHz per band with a dial that has a backlash of 100 Hz makes getting a voice to sound intelligible, let alone natural, an exacting task! It can be done, as improbable as that may appear initially. On top of those two characteristics, the receiver has an uncanny affinity for AM carriers. Comparing it with a Drake TR-4C on the 7150-7300 kHz segment discloses far greater interference from carriers (even during daytime reception) on the FRG-7. This test was made by switching the dipole from one receiver to the other with a coax switch.

The ceramic filter used in the final i-f of the FRG-7 really is not suited for SSB reception in crowded amateur bands.

Switching to a shortwave broadcast band quickly alters the unfortunate opinions that one may have formed while attempting to hear SSB signals. It performs quite creditably. The audio quality, of course, will not satisfy a "hi-fi" fan, but the limited frequency response stems from the comparatively-sharp i-f selectivity.

It's hard to fault the receiver's performance on CW. It tunes easily. It's rock-stable. It has a choice of three audio response curves. In short, it's a honey!

You'll notice I've omitted any listing of specifications, presuming you've looked over that information, scanning catalogues or dealers' handouts. I've just given you my impressions. For many years I've used only Drake or Collins receivers. The FRG-7 plainly is not in the same league as these. And, of course, at $299.00, you really can't expect it to be. If one comes down out of the clouds and sheds any delusions of getting three thousand dollars worth of receiver for three hundred dollars, he just may find the FRG-7 a very satisfying bit of equipment. Don't look for perfection; you won't find it! But if you look for a full-coverage receiver that'll do an excellent job of receiving CW, a very good job of receiving AM voice, and an acceptable (after you've gotten used to it) job of receiving amateur SSB signals — one that doesn't cost an arm and a leg — you'll have to search far and wide before you find one that'll top the Yaesu FRG-7. ■

SSTV Meets the SWTP 6800

-- modulate video with a micro

Soon after completion of my SWTPC 6800 system, I thought, "Now what can I do with it?" Since my hobby is ham radio coupled with an interest in SSTV, the answer was obvious. I decided to start in a small way with a program to load my WØLMD SSTV keyboard (Ref. 1). This project was quite successful, and I next attempted a more ambitious one — to generate SSTV in the CPU main memory. It became obvious that to generate SSTV I must first slow the microprocessor way down to accomplish the proper timings. I started by writing a short feasibility program which generated timing pulses and video in the proper relationships. I fed these pulses into an SSTV modulator which uses only three ICs and is external to the SWTPC 6800 system. This program's performance exceeded my expectations; however, it had one large drawback. The picture dot patterns had to be entered a byte at a time into the main memory which was a big job. This article tells about my third program, which automatically loads memory and generates SSTV pictures.

The system.

00	00	F0	80	00	00	FF

Fig. 1. Hexadecimal representation of seven picture dots in memory.

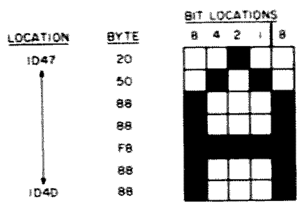

Fig. 2. Coding of the dots to form the letter A.

Memory Location	Present Value	Name
031A	75 (Hex)	Number of lines/ picture Half frame = 45
02E3	80 (Hex)	Horizontal line freq. 80 = 15 Hz (USA) 70 = 16-2/3 (Europe)
02E4	5D (Hex)	Sync pulse width Horizontal = 5 ms Vertical = 30 ms

Table 1.

Sample SSTV generation with some unwanted ac ripple sneaking into the monitor to mess things up!

The Specifications

I think a short technical discussion is in order as to how I accomplish this. I first decided on a few basic specifications which were taken from my WØLMD keyboard design. These were:

1. An SSTV picture will contain 30 ASCII characters in a 5 x 7 dot matrix pattern.
2. An SSTV picture dot will consist of three scan lines (vertical) and 1 dot (horizontal).
3. An SSTV picture will consist of 117 scan lines.
4. An SSTV scan line will consist of 7 eight bit bytes (6 data, 1 sync).
5. An SSTV picture in the SWTPC 6800 memory will consist of 819 bytes (117 lines x 7 bytes/line).

As you can see from these specifications, the memory requirements are quite negligible and my first feasibility program fits easily into the 4K of memory provided with the basic SWTPC 6800 system.

Well, now that we have a set of specifications, how is the programming accomplished? The only programming language which makes sense in this application is assembly language. The 6800 assembly language instructions coupled with the use of MIKBUG makes programming the SWTPC 6800 system an easy task. My first job was to flowchart the entire program, which is a highly recommended practice for anyone attempting such a project.

The Seven "Picture Bytes" — and the Software

Now let's examine in general how the seven picture bytes are used to generate the various sync pulses or picture dots. An example is shown in Fig. 1.

The example represents a typical SSTV scan line in memory. The first operation the program does in the transmit mode is load from memory the first byte into an accumulator. The accumulator in the 6800 is a powerful register which can be used to add, compare, or shift data. This byte is compared to see if it is FF. If it is, then it is a sync pulse. If not, it must be a data byte. The accumulator is then shifted to the left a bit at a time. If the shifted bit is a one, then bit 0 of the parallel interface adaptor (PIA) is turned on.

If the bit is zero, then the interface bit is turned off. If the byte is a sync byte (FF), then interface bit 2 is turned on for 5 or 30 milliseconds. Sound easy? Well, it is. All that is required is to connect these pulses to an SSTV modulator and out come SSTV pictures. Obviously, programming delays must be executed between all steps. Three program constants control all of these delays: one for the horizontal line frequency, one for the sync pulse durations, and one for the number of scan lines. Just think of the possibilities! By manipulating these constants, any number of scan lines can be transmitted (up to 117) at any frequency, which is only limited by the CPU cycle time and memory speed.

The generation of the SSTV is quite easy; the biggest trick is to place the correct dots in the picture at the correct location. This is accomplished by use of a translate table and a dot table. The translate table is used to tell the program

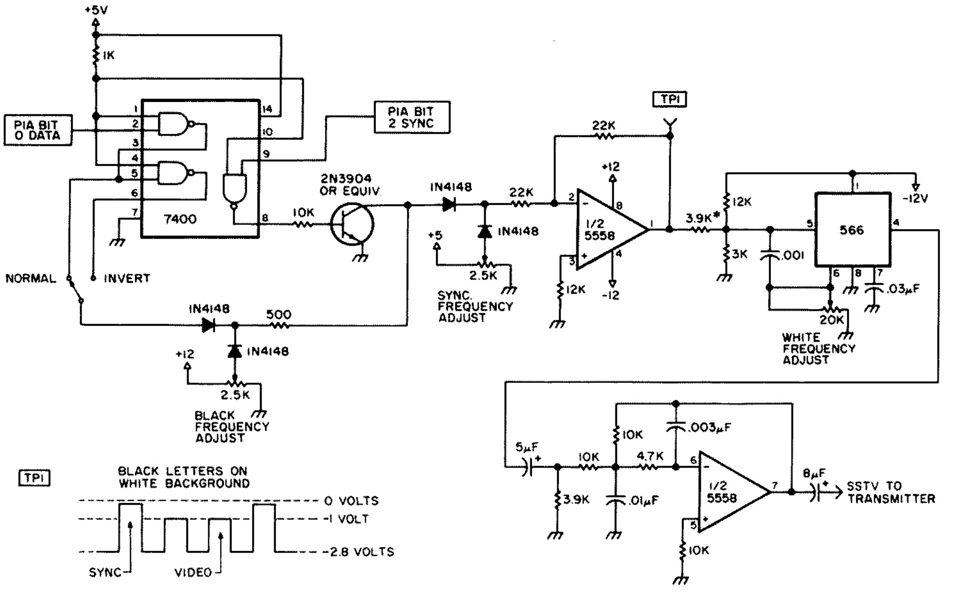

*Fig. 3. SSTV modulator schematic. *Adjust value of resistor if required for correct SSTV frequency swing.*

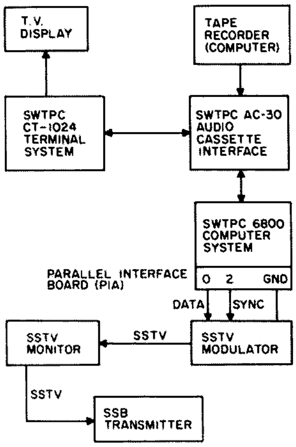

Fig. 4. Block diagram of computer hardware interconnections.

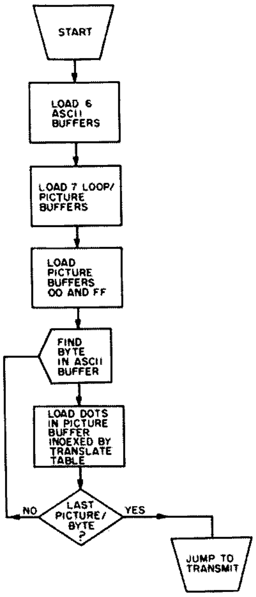

Fig. 5. Load SSTV picture program flowchart.

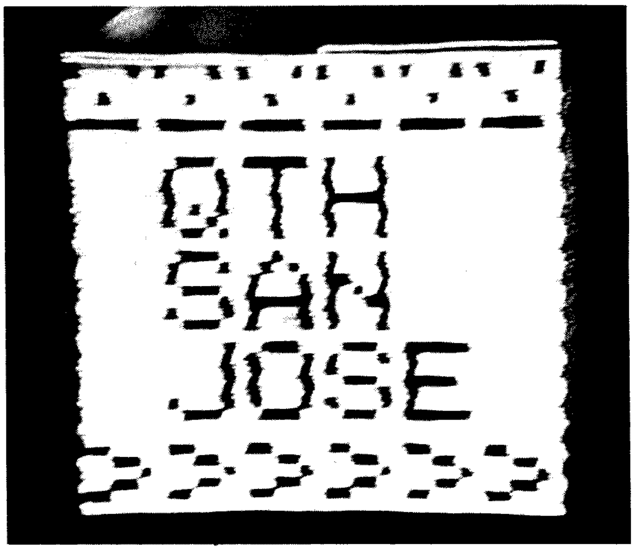

Another sample (along with the ripple).

where in the dot table the correct dots are located. The dot table is a 5 x 7 ASCII dot matrix array of bytes. The character dots were taken from the specification sheet of the 2513 Character Generator ROM chip (Ref. 2). Not all characters (ASCII) were coded in this program, due to their uncommon usage. The translate table in this program allows for expansion of 13 dot patterns without rewrite of my generator routines. The reader can code any of the patterns to suit his needs. In order to accomplish this task, I should explain in detail how the various tables are coded. Fig. 2 is an example of how to code the dots for the letter A.

As you can see, you are only limited by your imagination. With a little ingenuity, a set of graphic-like dot patterns can be created. The translate table in memory is contiguous with the dot table. The low order address of the translate table is equivalent to 6 of the 8 ASCII code bits. For example, let's take the letter A. The ASCII code for A is 41 hex. If you strip off the 8 and 4 bits, the code remaining is 01 hex. If you look in the translate table location 1D01 (hex), you will find a 47. This value means that the address of the dot bytes for A are located at 1D47 in memory. You will find in the translate table (1D00 to 1D3F) a number of 04 characters. This value is a blank character and is placed on numbers with ASCII codes between 21 and 2D. The characters are rarely used and 13 of these codes can be used for special graphics. The character codes (ASCII) 5B-5F will load characters with an inverted VEE. Now that you have a rough idea of how the program operates, let's use it.

The program makes a few assumptions about how your 6800 system is configured:

- The PIA card is in location 7 (address 801C).
- MIKBUG or equivalent is used, with the following routines: E07E – output a string of characters; E1D1 – output a single character; E1AC – input a single character.
- At least 8K of memory.
- PIA bits 0 are data pulses and bits 2 are sync pulses.

The PIA can be changed easily on any bit convenient on your system. Some of the program constants which can be modified to fit your specific requirements are shown in Table 1.

The program can be executed by loading MIKBUG location A048 and A049 with 0000 and typing G. The first routine executed is LOAD. This routine loads the picture buffers as you type in. The first message printed on the TV terminal is:

PICTURE FORMATS 0-5
1 2 3 4 5

The program is now asking for you to load 5 lines of 6 characters each. You first type in the picture number you want to load followed by 30 characters. The first character of each line will be placed under its corresponding line number.

You can now load all 6 pictures or type an ASCII letter to end the process. The next message printed on the TV terminal screen is:

SELECT LOOPS-PICTURES
LOOP MAX=9
?

The program is now asking

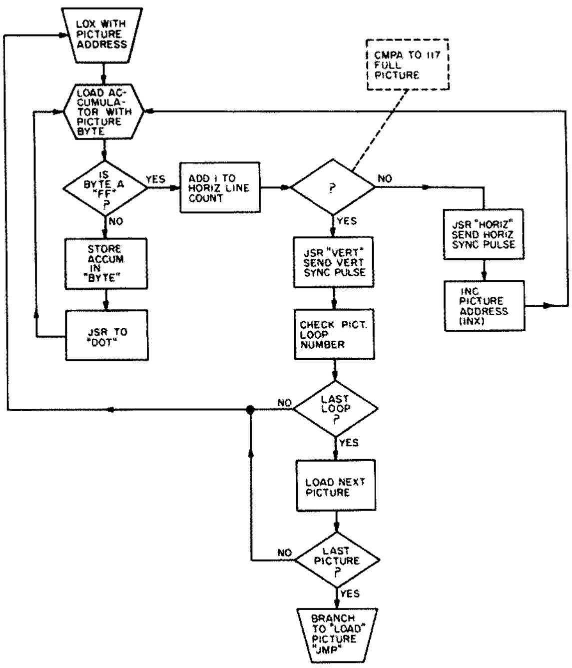

Fig. 6. Transmit SSTV picture program flowchart.

Program B. Hexadecimal object listings for SSTV generation program.

can enter up to 7 loops/pictures and the process can be terminated by entering an ASCII letter for the loop number. An SSTV picture can be looped up to 9 times. This type of programming will provide over 8 minutes of SSTV. Seven loop/pictures are entered with loop counts of 9. Upon entry of the 7 loop/pictures, the SSTV transmission is executed. After transmission, the program branches back to the load routine.

Summary

This completes the description and operation of the program. If you require more information, please write. All letters with enclosed return postage will be answered. Fig. 3 is an SSTV modulator which I use. The circuit was constructed on a vectorboard and installed in a minibox. The design is quite straightforward and can be duplicated with little cost and difficulty. The timing pulses are interfaced to the computer by a 7400 NAND gate. White letters on a black background or black letters on a white background are selected by an SPST switch. The video and sync pulses are mixed by 4 diodes, 1 IC, and 1 transistor. This video then drives a 566 function generator. The output triangular waveform is shaped into a sine wave by the output active filter.

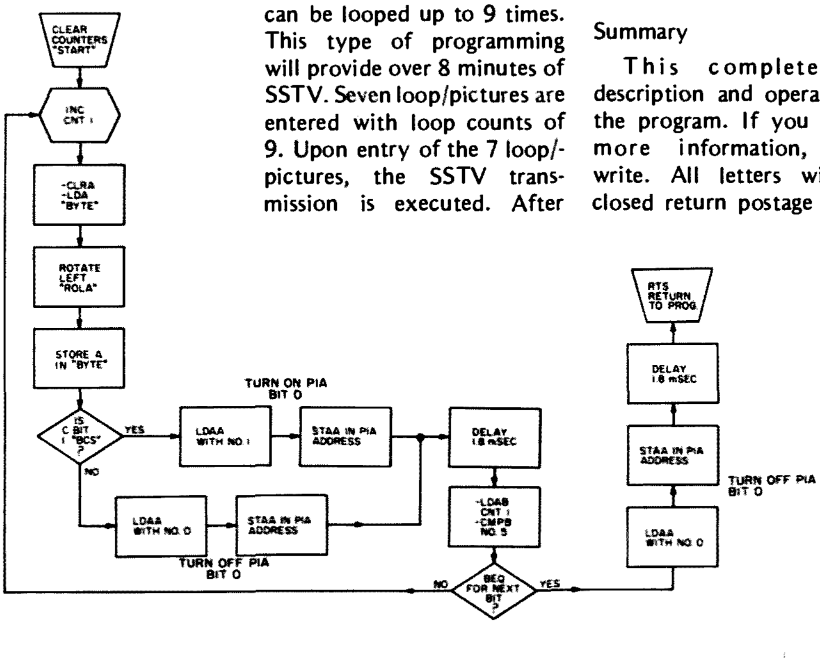

Fig. 7. Transmit SSTV picture dot program flowchart.

Conclusion

Fig. 4 is a block diagram of the hardware configuration of my system. Figs. 5, 6, and 7 are flowcharts of the three

```

Program A. Source listings for SSTV generation program.

you to type in the number of times each SSTV picture is transmitted. For example, a 3 loop would transmit approximately 24 seconds (3 x 8) of SSTV. The program will then respond with a slash after you enter the loop number. It will then wait for the picture you have just loaded (0-5). You

routines which make up the software. The flowcharts should be useful to anyone who wants to build this system around another microprocessor.

I hope you will enjoy using this SSTV generator. Over-the-air reports have indicated that the video is considerably more readable under QRM conditions than my WØLMD keyboard. The use of microprocessors are an obvious choice for the generation of SSTV. Considering that my special purpose SSTV keyboard is complex (44 ICs) and my SSTV 6800 generator runs on an unmodified SWTPC 6800 this proves that the microprocessor is the way to go for SSTV. ■

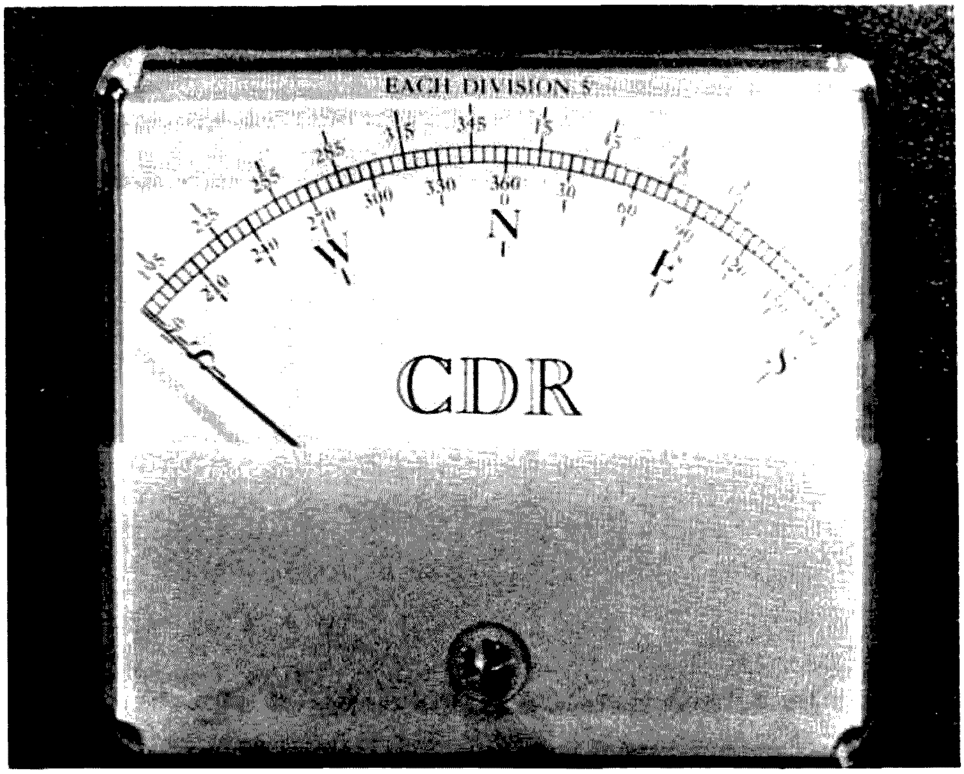
Aim Your Antenna With a Micro

-- beam heading BASIC program

Dennis Bodson W4PWF
233 North Columbus Street
Arlington VA 22203

Bob Fenichel WA2TMT/4
1201 South Courthouse Road
Arlington VA 22204



What direction?

This article describes a computer program that can provide accurate azimuth and distance information for properly aiming your beam antenna. Although the program was originally written in FORTRAN language for use with an IBM 370/155 computer, accessed through an IBM time-sharing terminal, the program is also presented in BASIC language. Also, the program can be modified to run on a microcomputer instead of through a time-sharing terminal.

Background

In the past year, several articles have appeared in *73 Magazine* describing methods of calculating beam bearing and distance. Two of these articles were "Aim your Beam Right" by WB4GVE (June, 1976) and "Global Calculations for the DXer" by W2IAT (August, 1976).

WB4GVE's article provided a method whereby azimuth information can be obtained using an HP-55 calculator. The basic azimuth equation is:

Degrees Azimuth =

$$270^\circ - \mathrm{Tan}^{-1}\left[\mathrm{Cos}\,\theta_1\left(\frac{\mathrm{Tan}\,\theta_1\,\mathrm{Cos}(\phi_2-\phi_1) - \mathrm{Tan}\,\theta_2}{\mathrm{Sin}(\phi_2-\phi_1)}\right)\right]$$

where

θ_1 = latitude of your QTH
ϕ_1 = longitude of your QTH
θ_2 = latitude of the distant QTH
ϕ_2 = longitude of the distant QTH

W2IAT's article described a procedure for determining the distance in statute miles between two stations using a non-programmable calculator. The basic equation for calculating the distance between any two points along the earth's surface in statute miles is:

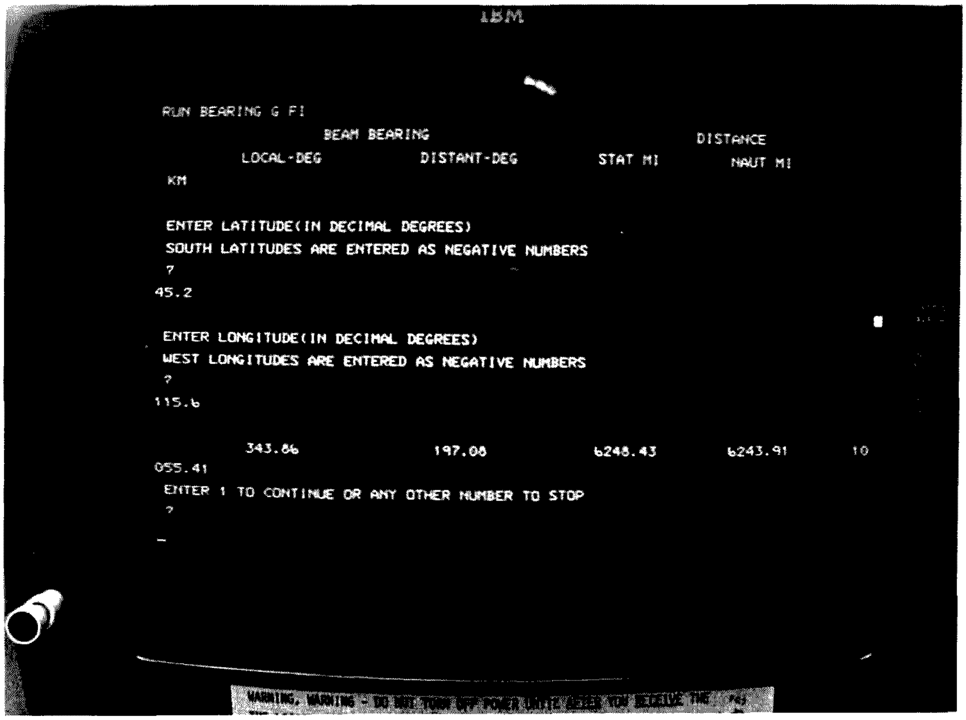
$$d = 69.05Z$$

$$Z = \left[\mathrm{Cos}^{-1}\left[(K_1)(\mathrm{Sin}\,LAT_D) + (K_2)(\mathrm{Cos}\,LAT_D)\,\mathrm{Cos}\,(LON_D - LON_H)\right]\right]$$

where

d = distance in statute miles
K_1, K_2 = constants determined by latitude of your QTH
LON_D = longitude of the distant QTH
LON_H = longitude of your QTH
LAT_D = latitude of the distant QTH

It should be noted that the constant used (69.05) is not the same as used by W2IAT (69.15). The appropriate constant for statute miles may be found in "Radio Data Reference Book," Second Edition, Radio Society of Great Britain (RSGB), p. 103, and "Reference Data For Radio Engineers," Fifth Edition, Howard W. Sams & Co., pp. 26-10.

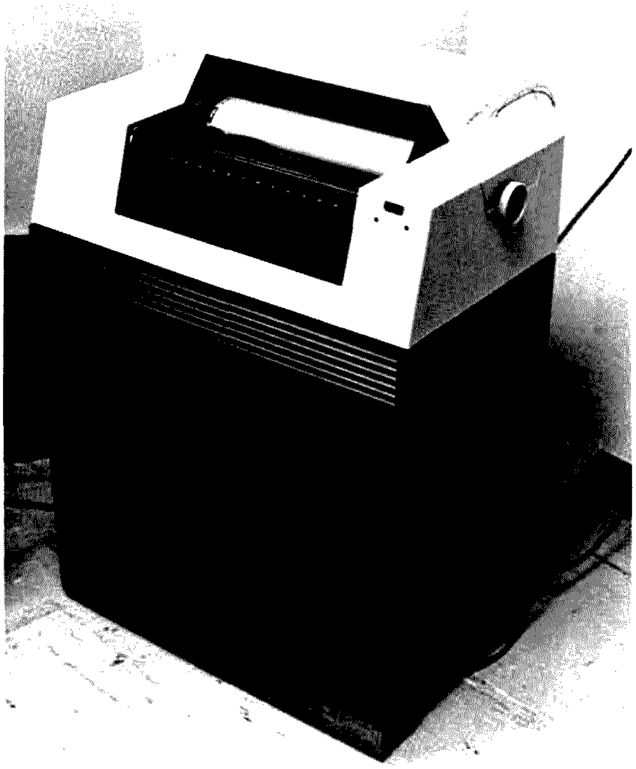


IBM 3277 time-sharing terminal.

Development

Calculating beam bearing using a computer instead of a calculator provides several distinct advantages. For one thing, a computer system can provide a detailed printout of the results for later use. Another advantage is that,

An actual terminal screen display.



IBM 3284 printer.

Fig. 1. Computer program statement listing (FORTRAN).

not having a programmable calculator with "power-off" program storage, using a computer enables a program to be saved from one run to the next.

In developing the program, use was made of the basic equations for calculating azimuth and distance cited earlier. These have been built upon to provide beam bearings for use at both the local and distant stations and to furnish the surface distance between the two locations in statute miles, kilometers, and nautical miles. The program provides prompting for keying in coordinates and can display beam bearing (azimuth) and distance information on both the terminal screen and on an external page printer.

FORTRAN Program Details

Fig. 1 shows a listing of the 64 FORTRAN statements making up the computer program. Statements 10-30 write the headings 'beam bearing' and 'distance' on both the terminal screen (6) and an output data set (2) for possible later printout. Statements 40-60 write the subheadings 'local-deg,' 'distant-deg,' 'stat mi,' 'naut mi,' and 'km' the same way as the previous write statements, but on the next line. The "T" format is used to tab the subheadings across the lines in the same manner as a typewriter tab mechanism. Statements 80-100 write a blank line (space 1 line). Statements 110-150 prompt the user to enter the latitude and label it PLAM2. Statement 150 reads from the keyboard (5) in a flexible format (*). Statements 160-170 write a blank line on the screen (space 1 line). Statements 180-220 prompt the user to enter the longitude from the keyboard and label it PL2. Statements 230-240 write a blank line on the screen. Statement 250 assigns the variable PIE the value of pi (3.14.....). Statements 260-270 convert both local and distant latitudes from decimal degrees to radians. Statement 280 assigns variable N the value 1 (to be used later in the program). Statements 290-300 convert both local and distant longitudes from decimal degrees to radians. Statement 310 will be used to branch back to that point in the program from a later statement in the program. Statements 320-330 compute the beam bearing from one location to another. Statements 340-350 ensure that the beam bearing chosen is the shorter of the two possible (.LE. stands for "Less than or Equal to"). Statement 360 branches around statements 370-470 if N=2. Statements 370-470 reverse local and distant longitudes and latitudes, assign the variable Y to the previously computed beam bearing, set N=2, and branch back to statement 310 to compute beam bearing from the distant to the local QTH. Statement 480 is branched to from statement 360 if N=2 (both bearings

have been computed). Statements 490-520 compute the distance between the two locations. ABS (absolute value) strips off any negative sign and '.GT.' stands for "Greater Than." Statements 530-550 convert the distance to statute miles, nautical miles, and kilometers. Statements 560-580 write the answers under the appropriate subheadings on both the terminal and the output data set (for later printout). Format F6.0 means the number is printed in 6 spaces with no decimal places. Statements 590-610 prompt the user in determining whether to compute again using a new set of inputs or end the run. Statements 630 and 640 terminate the computer run.

BASIC Program Details

Fig. 2 shows a listing of the 63 BASIC statements used in rewriting the program in that language. Statements 10-60 prompt the user to enter distant latitude. Statements 70-110 do the same for distant longitude. Statements 120-210 perform the same function as FORTRAN statements 250-330. Statements 220-260 perform the same function as FORTRAN statements 340-350. Statements 270-390 are equivalent to FORTRAN statements 360-490. Statements 400-420 replace the IF statement on line 500 of the FORTRAN program. BASIC language does not contain an arc cosine (COS^{-1}) function. Therefore, the mathematical series giving a close approximation to this function has been substituted in statements 430-470. The series used is:

$$\cos^{-1} x = \frac{\pi}{2} - \left(x + \frac{x^3}{2\cdot3} + \frac{1\cdot3x^5}{2\cdot4\cdot5} + \frac{3\cdot5\cdot x^7}{2\cdot4\cdot6\cdot7} \cdots\cdots \right)$$

Statements 480-510 are equivalent to FORTRAN statements 520-550. Statements 520-580 print out the bearing and distance information. Statements 590-620 prompt the user in choosing between recomputation for another set of longitude and latitude and program termination.

Fig. 2. Computer program (BASIC).

Operation

After "signing-on" the time-sharing terminal, the program is called up for use and run. Immediately the headings and subheadings are displayed on the terminal screen. Then, the phrases "Enter latitude (in decimal degrees)" and "South latitudes are entered as negative numbers" appear on the screen. The desired distant latitude is then typed on the keyboard by the user. The same procedure is followed next to enter longitude. Computed values for beam bearing and distance then appear on the screen under the appropriate subheadings. At this point, the program will prompt the user with "Enter 1 to continue or any other number to stop." If a "1" is entered, the program will again prompt the user for new latitude and longitude values and will compute a new line of computed

Regulated Nicad Charger

- - don't cook 'em!

More and more nicad cells are becoming available and many hams are utilizing them in portable rigs and test equipment. To avoid damaging these batteries though, a few precautions are necessary:

1. Always utilize the full capacity of the cell. Nicads have a sort of "memory" action and a unit that is habitually required to provide only ½ of its rated capacity will go dead at that half way level when the whole bit is needed.

2. Don't reverse charge a nicad. Keep the charge condition on all cells in a series string at the same percentage rate. Substitution of a partially charged cell into a series string of fully charged units may ruin the weaker cell through reverse charging.

3. When charging standard nicads (other than "Quick-Charge" units), limit the charge current to about 1/10 the rated Ampere-hour capacity. Excessive charge current causes overheating, which may result in seal rupture and venting of excess pressure. Once the seal is broken, the cell will rapidly dry out and become useless.

Item 3 above leads right into the reason for this article. Fig. 1 is representative of a "universal" type nicad charger circuit.

The transformer, rectifier, and filter capacitor are conventional design. The transformer itself is an 18 volt doorbell unit which gives a rectified dc output of 25 volts.

The current regulator is somewhat less conventional, as most hams are familiar with the emitter follower circuit in Fig. 2. Placing the load in the collector circuit as in Fig. 1 allows a measure of gain and results in better current limiting action.

In Fig. 1, resistor R1 is used to provide forward bias to the base of Q1, bringing that transistor into conduction. With no collector load (batteries) in the circuit, the emitter current is very low. Thus the resulting voltage drop across the base-emitter junction and R2 is not adequate to forward bias the two diodes, D1 and D2. This leaves the transistor in a full-on state with the whole supply voltage present at the output terminals.

Now, if we put a heavy load (0 Ohms) across the output terminals, the current will increase(!), but how much? Watch what happens. As the current increases, the voltage drop across R2 also increases. When the base-emitter drop plus the R2 drop reaches approximately 1.2 volts, the two diodes go into conduction and limit any further increase in base potential. Thus the current is limited to that point where the emitter circuit voltage drops equal the series turn-on potential of D1 and D2.

For silicon diodes, the turn-on potential is about 0.6 volts. This also holds true for the base-emitter junction of silicon transistors. This means that the required value for R2 is about 0.6 volts divided by the current limit desired.

Varying the load (using 1 to 18 nicad cells) reveals that the current limiting action will hold within 1 to 2 mA from 0 to 24 volts. In other words, you can charge any random number of cells from 1 to 18 without adjusting the charger.

Transistor Q1 should be chosen for a reasonably good hfe and a power capability of twice the total supply voltage times the current limit value. Since my primary interest is in 450 mAh penlight cells, my charge current is set at 45 mA. This means that my transistor must dissipate 25 volts times 0.045 Amperes, or 1.125 Watts. Double that for safety and a 2 Watt transistor is about right. ■

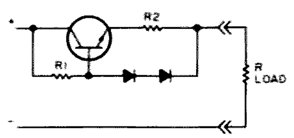

Fig. 2.

Complete Repeater Control System

-- all that's missing is the computer

E. E. Buffington W4VGZ
2736 Woodbury Drive
Burlington NC 27215

You can build a repeater that will perform better than many commercial units. You can do it with six small plug-in circuit boards, a transmitter, and a receiver. Three of these boards were described in *73* recently in connection with autopatch. The circuits described in this article are made to interface with the autopatch boards.

CW Identifier

The K2OAW identifier is repackaged into a 22 pin plug-in 4 x 6 inch board. This circuit was presented in the February, 1973 issue of *73 Magazine* in an article by Pete Stark. I did add an audio oscillator for feeding the audio board described in *73*, April, 1977. The circuit master, schematic, parts layout, and parts list are provided for you to duplicate Pete Stark's excellent design in a more convenient layout.

Timer Board

The timer board has the four second tail timer, the three minute timeout or "windbag" timer, and the five minute ID timer.

Request for transmitter on can originate from a signal being received (COS), local microphone (PTT), autopatch (AP), and the CW identifier board (ID HOLD). The shutdown control (TRANSMITTER ENABLED) is also an input. The four second and three minute timers are resettable by the action of the 2N3906 transistor which, upon being triggered, partially discharges the timing capacitor. This reset does not result in four more seconds or three more minutes, as only about half the delay can be reset out.

The ID timer and logic will start the identifier initially with COS, PTT, or AP going low, and will identify five minutes later. It is possible for two IDs to take place one after another if the five minute timer runs down and just afterwards COS goes low. I am working on a new logic scheme that will result in less extraneous IDs. I will try to lay it out so that it will plug in the same socket so that no wiring changes to the socket are necessary.

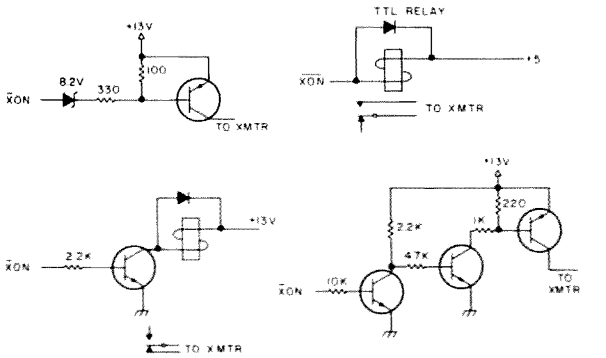

Fig. 8. Suggested transmit switching circuits.

or on the machine. The (A) and (B) buttons of the 16 button pad are pressed alternately to do this. The 74123 (a retriggerable multivibrator, Z7) is used as a half-second debouncer. In the article (April, 1977) on autopatch, I included the schematic for a (*) and (#) one-second debounce circuit. This circuitry is included on this board. The neon optoisolator only draws 2 mA from the phone line during ringing. A means for manually advancing the counter using a push-button is shown on the overall schematic. The 10k Ohm resistor and the 1 uF capacitor connected to pin 6 of Z1 insure that after a power failure the circuit will come on with the transmitter enabled.

Repeater Shutdown Board

This circuit is a must for remote controlled repeaters. This one will count the rings on the phone line and shut the repeater off by the "transmitter on enable" line going low. As a convenience and backup feature, touchtone in the fourth column can also be used to turn off

The Extender

A circuit master is included for an extender card. This card is soldered to a 22 pin connector. If you mount your circuit boards so that both sides are accessible for adjustment or test, then you will not need this aid (your boards will take up a lot of space though).

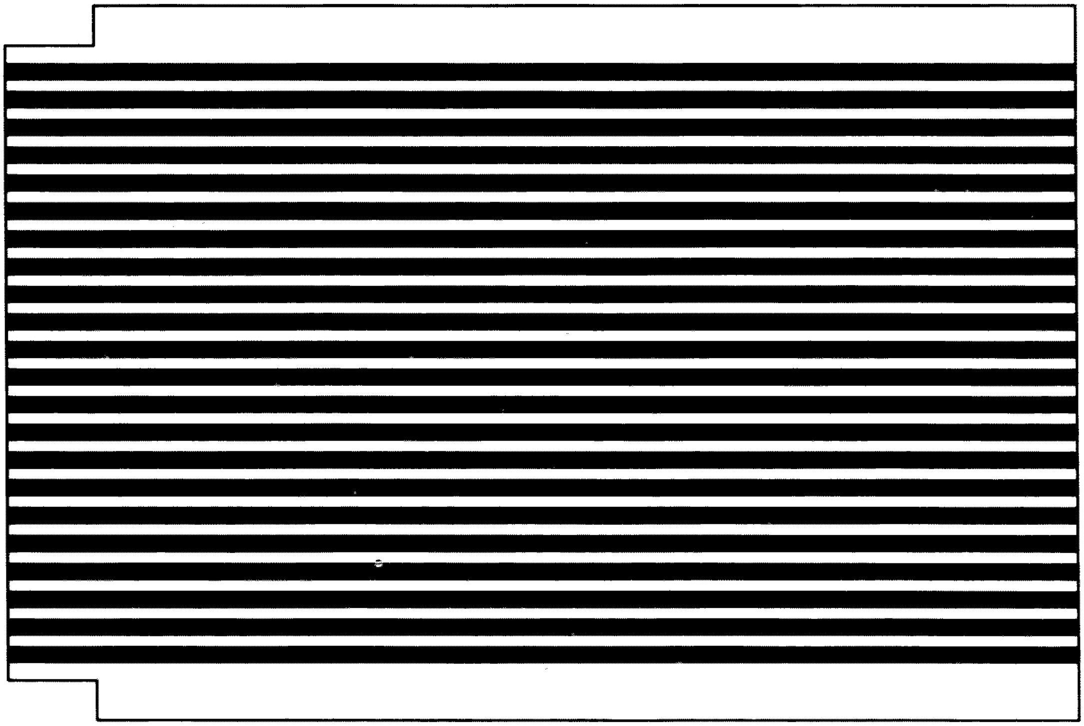

Fig. 9. Extender board.

Interfacing

The six boards will require very little to interface with a receiver and transmitter. An active high of three volts or so is needed from the receiver as a carrier operated switch (COS) signal. The receiver audio input to the audio board can come directly from the discriminator over a shielded wire. The 470k Ohm resistor on the audio board is large enough so that loading of the discriminator should not be a problem. A few circuits are given as suggestions for turning on the transmitter. You can, I am sure, think of a better one to fit your individual transmitter. A similar circuit can be used for the (AP) signal turning on the tape recorder.

If you use all six of these boards, you should remove the MC7805CP from the dialer board and mount the regulator on a good heat sink, as the five volt load will be near an Amp and the MC7805CP does not have enough heat sink mounted to the dialer circuit board.

Fig. 10. Parts list. Circuit boards and parts can be obtained from: Stafford Electronics, 427 South Benbow Rd., Greensboro NC 27401, (919) 274-9917.

Parting Shots

So good luck with your repeater project and please let me know about it. A QSL card with "it works" would be OK. If you have trouble getting any of the parts, send an SASE and I will try to help you find a source. Try the ads in *73* first because that is where I get most of the parts I use. In a project this large, errors are bound to creep in. Let me or the editor know about it and corrections can be made. ■

Transmission Line Primer

-- in case you don't know everything

J. A. Murphy
3431 Oakdale, Apt. #2102
San Antonio TX 78229

A number of articles have appeared in the amateur literature in the past few years attempting to "explain," or perhaps "explain away," the concept of reflected power on transmission lines. The conclusions reached by some of the authors range from "It doesn't seem to make any difference, so why worry about it?" to "I can't understand it, so it must not exist!" But of course reflected power does exist; part of the signal arriving at a point of mismatch on a transmission line is reflected back down the line just as surely as part of a radio signal striking the moon, or part of a radar signal striking an airplane, is reflected back the way it came. So the problem is in understanding how a transmission line operates. What seems to be needed is a new (to the amateur fraternity at least) way of looking at the problem.

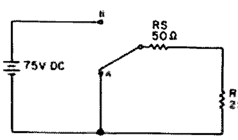

Fig. 1.

In the field of high speed digital logic, the characteristics of transmission lines and the effects of reflections on these lines is far more critical than in most radio communications systems. Luckily, the operation of a line driven with step functions or narrow pulses is also much easier to analyze than that of a line driven with constantly varying signals such as sine waves. Let's look into a very simple "digital" circuit consisting of a battery, a couple of resistors, and a chunk of cable. The analysis requires only the simplest of algebra and will provide tremendous insight into the whole subject.

First let's consider the trivial circuit in Fig. 1. When the switch is moved from contact A to contact B, a current of 1 Amp flows through the battery and both resistors, dropping 50 volts across RS and 25 volts across RL. Simple enough. Now let's move on to the circuit in Fig. 2, in which a long piece of cable, or transmission line, has been added. Now if we ignore the small resistance of the cable, we might expect this circuit to behave exactly like the first one. But it doesn't, not exactly! Remember that signals propagate along a transmission line at a finite speed; granted, it is a very high speed, usually greater than half the speed of light, but still a finite speed. This speed is specified by the line's velocity factor, which gives the speed of signal propagation on the line as a fraction of the speed of light. For most of the lines used by amateurs, this factor is about 0.66. That means signals propagate along the line at 0.66 times the speed of light, or about 0.66 feet per nanosecond. Then if our line in Fig. 2 is 660 feet long, it will take a signal 1000 ns, or 1 us, to get from one end to the other.

When the switch in Fig. 2 is thrown, current starts to flow through the battery, RS, and the end of the line. But it doesn't make it to the far end of the line, and RL, for 1000 ns. The obvious question at this point is "*How much* current flows during that 1000 ns?" Since there is no current at the far end of the line or in RL, then the value of RL can have no effect on the current. The only things controlling the current are the battery voltage, the value of RS, and the parameters of the line. The pertinent line parameter here is its characteristic impedance, or surge impedance. You've probably seen this defined as the impedance that would be seen looking into the end of an infinitely long line. It is equivalent, and perhaps easier to grasp, to say it is the impedance seen at the driven end of a cable before the signal has had time to reach the other end. And from that it follows that the line's characteristic, or surge, impedance (call it Z0), is the impedance seen by any signal moving along the line, that is, any wave propagating along a line always has its voltage equal to its current times Z0. Actually we've put the cart before the horse; the last statement is more nearly the textbook definition of Z0, and the previous two statements follow from it!

So if Z0 for the cable in Fig. 2 is 50 Ohms, the current through RS right after the switch is thrown is .75 Amps and the voltage across the near end of the line is 37.5 volts. If we look at the line 500 ns later, we find 37.5 volts across it at all points from the near end up to the middle and 0 volts at all points from the middle to the far end. Similarly we find .75 Amps flowing in the line at all points up to the middle and no current beyond. We are observing a signal, or wave front, or step, of 37.5 volts and .75 Amps propagating along the line at the rate of 0.66 feet per nanosecond.

Now let's consider what happens after 1000 ns, when the step reaches the far end of the line and RL. The ratio of voltage to current on the line is 37.5/.75=50, the line impedance. The ratio of voltage to current at RL must be the value of RL, or 25. So either the voltage, the current, or both must change. (Note that if RL were equal to Z0, no change would be necessary, steady state conditions would be reached in 1000 ns, and the only effect of the cable would be a time delay.) If either the voltage or the current at the far end of the line changes, this change won't be seen at the near end for another 1000 ns, during

which time the change propagates back along the line. This change traveling back along the line is called a reflection! But, as we have seen, any signal propagating along a line must have its voltage and current related by Z0. Thus the ratio of the change in voltage to the change in current caused by RL must be related by Z0. If we now designate the voltage and current moving from the near end toward the far end with a + superscript and those moving in the opposite direction with a - superscript, we can write three equations describing our findings:

$$E^+/I^+=Z0 \quad (1)$$

$$E^-/-I^-=Z0 \quad (2)$$

$$(E^++E^-)/(I^++I^-)=RL \quad (3)$$

Equation 1 says that the forward voltage and current are related by Z0. Equation 2 says that the reflected voltage and current are similarly related, but with an added - sign since the direction of propagation is reversed. Equation 3 simply says that the total voltage and current at the far end of the line, the sum of the forward and reflected waves, must be related by RL. The solution of these three equations for E^- and I^- yields:

$$E^-=(RL-Z0)/(RL+Z0)\cdot E^+ \quad (4)$$

$$I^-=(Z0-RL)/(Z0+RL)\cdot I^+ \quad (5)$$

Substituting the values from our example gives -12.5 volts for E^- and .25 Amps for I^-. Summing the forward and reflected components gives 25 volts and 1.0 Amp at RL.

Now let's follow the reflection back along the cable toward RS. If we look at the line 1750 ns after the switch was thrown, 750 ns after the reflection started, we will still find 37.5 volts and .75 Amps at all points in the first quarter of the line, but we'll see 25 volts and 1.0 Amp at all points in the last three quarters of the line. Remember that this 25 volts and 1.0 Amp are actually the sum of a forward wave (37.5 volts and .75 Amps) and a reflected wave (-12.5 volts and .25 Amps). We are watching a reflected wave propagate back to the near end of the line. After 2000 ns, the reflection reaches RS, where it sees a perfect match. Therefore, no changes in voltage or current are caused and no additional reflections are created. The reflected -12.5 volts combines with the 37.5 volts already present at the near end of the line to give 25 volts, the reflected .25 Amps combines with the .75 Amps already flowing giving 1.0 Amp, and steady state conditions are reached. Now the voltages and currents at the resistors are just like they were in Fig. 1. The steady state conditions of the two circuits are identical. The presence of the transmission line caused a transient condition, 2 us long in this case, to occur before steady state conditions were reached.

If we consider the battery and RS to be a transmitter and RL to be a load, in both Fig. 1 and Fig. 2 the transmitter delivers 25 Watts to the load once steady state conditions are reached. But in Fig. 2 the transmitter delivered 28.125 Watts to the line for 2 us. You might say the transmitter "thought" the load was 50 Ohms, the line impedance, and delivered power accordingly, until the reflected 3.125 Watt reflection got back and "told" it different.

So reflected power does exist. It's real, honest to goodness power, voltage in phase with current, capable of producing heat, doing work, or fitting whatever definition of power you care to use. And the job it does is "telling" the transmitter what's out there at the end of the line and forcing it to "adjust" its output accordingly. And if you're still worried about that "extra" power, consider what happens when you throw the switch back the other way. Again there is a 2 us transient condition. We continue to see 25 volts and 1.0 Amp (25 Watts) at RL for 1 us after the transmitter is turned off. And at the near end of the line we see -12.5 volts and .25 Amps (3.125 Watts) coming out of the line and being dissipated in the transmitter for 2 us! The "extra" power that we put into the line for 2 us when we turned the transmitter on came back out of the line for 2 us when we turned it off.

The circuit in Fig. 2 is just about the simplest possible case of line reflections. Now let's look at some of the reasons for its simplicity and see how things might get more complicated. Notice that we let the output impedance of our transmitter, RS, match the line impedance, Z0. This condition rarely exists in the real world! The widespread, and incorrect, use of the term "output impedance" to refer to recommended load impedance has led many people to believe that a transmitter designed to drive a 50 Ohm load has a 50 Ohm output impedance. While this is not impossible, it is highly unlikely. It takes a lot of extra work to make an amplifier of any kind, rf, audio, or anything else, have an output impedance anywhere near its recommended load impedance, and there is usually no reason whatsoever to try to do so. Except in very special applications, it would never even occur to the designer to think of such a thing! Therefore the reflected power will generally see a very large "mismatch" when it gets back to the transmitter and a considerable portion of it will be re-reflected. This means that, even in the simple dc circuits we've been looking at, the reflections, and the transient condition, will continue forever and the steady state conditions will never be reached but will be approached asymptotically by a series of discrete changes, or steps. This should not be too surprising, as it is very similar to charging a capacitor with a battery and resistor; the voltage on the capacitor never reaches the battery voltage, but approaches it asymptotically.

We also assumed we were dealing with a lossless line, a very difficult thing to come by! With any real line, part of the forward power is lost before it reaches the far end of the line, resulting in less power in the load and less reflected power. Similarly, part of the reflected power is lost before it gets back to the transmitter. This means that we've lost some of the information that "tells" the transmitter about the value of RL. Instead of "realizing" that the load is not Z0, but RL, the transmitter "thinks" that the load is something between Z0 and RL. This results in a little additional loss.

We also assumed the line was distortionless, or that it treated all frequencies in exactly the same way. This is another condition that is rarely even approximated in practice. The effect is to "round off" the nice square pulse we started with. Again this has no effect of the basics of reflections.

We have dealt only with impedances that were pure resistances, but while this greatly simplifies the math, it has no effect on the conclusions.

And finally we have only considered dc, or square pulse, conditions. But one of the basic principles of electronics tells us that if we know how a circuit responds to very narrow pulses, we can predict how it will respond to any other waveshape. We can create any arbitrary wave-

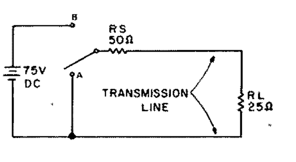

Fig. 2.

form by adding together a great number of narrow pulses and find the response by adding the responses to each of the pulses. When we consider sine waves, we must think of time delay in terms of phase shift and take into consideration the standing waves produced by the addition of the sine waves moving in opposite directions on the line. Things rapidly become much more complicated, but the basics remain unchanged: Any signal moving along a line does so with its voltage and current related by Z0; points of mismatch on the line cause reflections.

Please note that we've said nothing about the importance, or lack thereof, of reflections on overall system performance; that is not the purpose of this article. In a digital system, where the transmission line may be a couple of feet of hookup wire, or a few inches of copper on a PC card, reflections may be intolerable. In a relatively narrow band radio communications system, if the transmitter can operate into the load presented by the line, and the extra loss caused by reflections is tolerable, and the higher peak voltage caused by the standing waves doesn't break down the line, you can probably forget all about reflected power. The point is that reflections do exist, they are not a figment of some mathematician's imagination, and they don't violate any laws of nature!

So the next time you hear somebody claim that reflected power doesn't exist, or that the voltage and current in a reflected wave are always 90° out of phase, or that directional wattmeters can't be built, or any of the other absurd statements that are so often tossed about, sit down and draw a little circuit similar to Fig. 2 and think about it for a few minutes. All those stupid engineers are right after all! ■

Things Remembered

-- ever heard of an 807?

Daniel T. Davis W8LUX
1610 E. McKinley
South Bend IN 46617

I've never really been too certain about what it takes to be called an oldtimer — being licensed for 50 years, holding a two letter call, or perhaps having had your start with a spark gap transmitter. Whatever the specific element happens to be, memories have to play an important role, and this is an area where I'm making progress towards that "OT" designation.

After having been exposed to amateur radio for a quarter of a century and an actual participant in it for the past 20 years, I've begun to notice that a lot of things I once took for granted just aren't around any more.

Recently I put together a partial list of some of the things associated with amateur radio which were once important to me. Check it over and see if there's anything you recognize:

– Crystals for 80 and 40 meters that came in those rugged FT-243 holders.
– Those strange WV calls which were assigned to Novices briefly in the late 1950s.
– The thrill of using a VFO for the first time to explore the area below 3700 kHz.
– When you said "kilocycle" and everyone knew what you meant.
– A CW signal that was actually produced by a human being and not a device, mechanical or electronic.
– Blazing arguments about whether sideband would ever compete with AM.
– Transmitters that had a DSB mode.
– Building those Johnson or WRL screen modulators as a means of getting on phone inexpensively.
– Discovering that the screen modulator really worked.
– The night I actually heard someone over six meters on my Hallicrafters S-53A.
– Catalogs from mail-order electronics supply houses that were 200 pages thick.
– When six or seven manufacturers published catalogs.
– All those surplus equipment stores near Arch Street in Philadelphia where a 110 V ac DPDT relay cost a buck.
– Row after row of ARC-5 equipment in those surplus stores.
– An 807 which didn't become gassy after 50 hours of use.
– The Viking Adventurer, Globe Chief 90, Heath AT-1, and all the similar transmitters that made it possible for a Novice with a schoolboy's allowance to get on the air.
– Hearing the FCC examiner tell you that someone in Washington would send you your General ticket in about four weeks.
– Finding out that the examiner and the man in Washington were men of integrity.
– When you didn't have to own a linear and make an appointment to QSO on 20 phone.
– Something called 2½ meters.
– Or even 11 meters.
– Fidgeting with the BFO to unscramble those "Donald Duck" voices.
– A handful of guys fooling around with commercial FM gear on six meters.
– When it was rare to see a K-call in the "Silent Keys" column of *QST*.
– Almost coming to blows with someone over incentive licensing.
– When postage for a QSL card only cost two cents.
– An *enfant terrible* publishing a new ham magazine that was irreverent, humorous, and simply interesting to read.
– The *enfant terrible* has mellowed somewhat, but thankfully his magazine hasn't.

No, I'm neither ready nor qualified to be called an oldtimer. I really look forward to my next 25 years in ham radio, but in my "middle age" I can't help but look back and, like the well-known comedian, simply say, "Thanks for the memories." ■

Digital Bargain Hunting

- - tips on surplus computer goodies

Louis S. Macknik W8KBC
45A Scott Circle
Bedford MA 01730

The computer hobbyist hardware market has been moving very rapidly, with new products being introduced nearly every day. If you are like me, you want to have most of them, too! No budget can stretch that far, if at all. Balancing the endless list of necessary peripherals against a dwindling level in your checkbook is a lot easier to do if you can take advantage of the used electronics market. I would love to have one of those new $900 dumb terminals, but in many ways it makes more sense to shop for a $300 used one, repair it if necessary, modify it to be just as dumb, and put the remaining $600 (?) into more memory, a disk, or good software.

Rest assured, a surplus computer equipment world does exist. My impression is that it is merging with the surplus market that hams have ravaged for years, just as ham radio and the computer hobby seem to be merging. To introduce you to what may be available surplus, I'll give you a few suggestions to get started, and then describe one of my more profitable adventures.

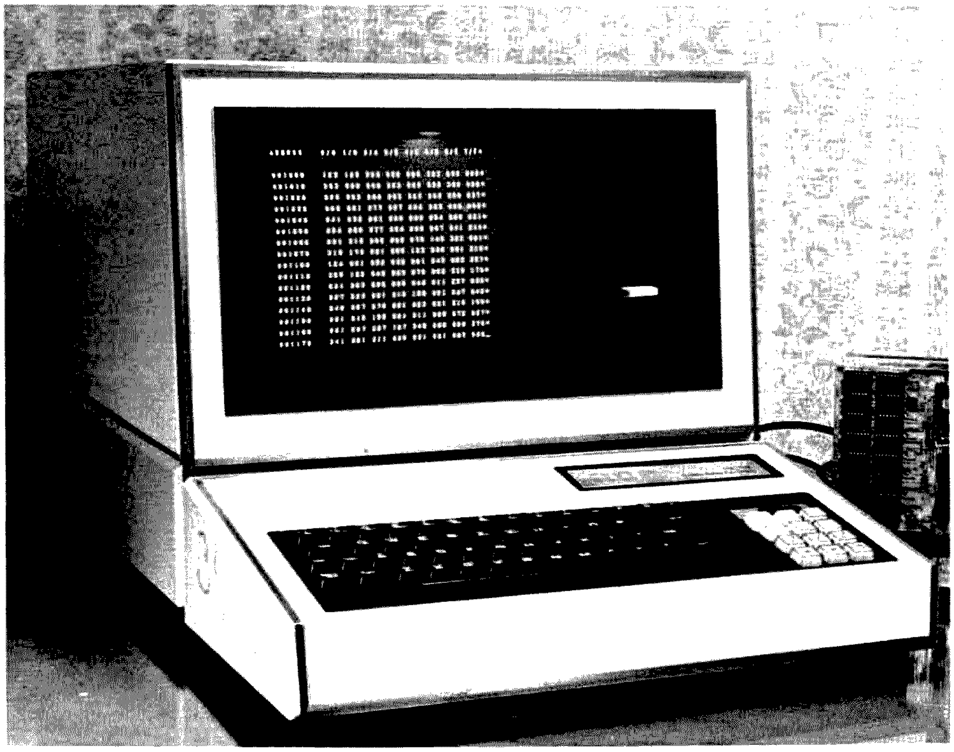

Photo 1. The RCA 70/752 Video Data Terminal has a hidden door to the right of the screen concealing controls for the display and alignment of the character generator. The keyboard can be moved up to one foot away from the display.

Preparation

First, you must convince yourself that digital equipment is not forbidden fruit into which you must not byte. I am reminded of the ham home brew enthusiast who for years builds test equipment, antennas, and transmitters of unending complexity, yet never touches his receiver or builds one because *a receiver is too tough to handle!* If you have an electronics hardware background, you have a head start and should not be intimidated. If you are a software expert trying to assemble your own system for the first time, there are a lot of people in computer clubs, ham clubs, and elsewhere who can help you. In any case, the best way to gain an appreciation for a new discipline, hardware or software, is to get your hands not only on it, but into it as well.

The second thing you must do is use common sense to gain an eye for the bargain. I've been burned a few times and went home with nothing more than a fancy boat anchor, but never for any great sum of money. After all, the higher the price, the more careful you automatically become. This field is moving so rapidly that a piece of gear which creates nausea in a state of the art hobbyist

could very well be only two or three years old and provide a lifetime of service at a fraction of the original cost. Look for equipment being offered with spare parts, or gear which uses the type of components you've seen advertised in the back pages of magazines. You should also look at each item with an alternative project in mind just in case you do goof (*caveat emptor*). For example, you buy a floating point box to do hardware arithmetic and then discover that it was the victim of a slight overvoltage. The box or card rack it came in is probably worth the cost and can be used later (I know, I can't get *my* car in the garage, either). An operations or maintenance manual sold with the equipment can be worth its weight in gold, but don't be fanatical about it. Many times you can reconstruct all you need to know by studying the equipment itself. After all, one goal of most hobbyists is to replace hard cash with personal time spent pursuing the hobby.

You should also know the market if you are to take advantage of it. Find out where the surplus houses are, what their specialty seems to be, and get on the mailing list for any flyers. Have a general knowledge of what a bargain price is so that you can make an intelligent decision when you come across that 400 pound transformer you desperately need to beef up your power supply. Read the ads in the back pages of magazines and have a feel for the current prices on used or surplus prime components.

Interested? Well, let me use one of my experiences to illustrate and at the same time describe one of the bargains available. For those of you who would like to have a used CRT terminal, but are not sure such things can be used by hobbyists, the following is a description of the RCA 70/752 Video Data Terminal, shown in Photo 1, and how I put it to use. For those of you who recognized it as a bargain and have one in your garage, drag it out, because the modifications I'll describe can be completed in minutes.

The Bargain

One day while watching my home brew 8008 system blink its LEDs magically, the mail brought me a flyer advertising the RCA 70/752 VDT (Video Data Terminal) with spare parts for $200. Smelling a bargain, I rushed to the store to examine it. It was a complete terminal with a 12-inch display of 20 lines of 54 characters (1080 total) and a detachable matching keyboard. It used a 1200 baud RS-232 interface and had internal memory. The keyboard was mechanical (IBM style) but was missing parts. The keyboard enclosure had extra function keys for cursor control and for *editing*, including single character erase, single line erase, full screen erase, and a mode for inserting data such as letters left out of words. There seemed to be many circuit boards inside with discrete components that had easily identifiable markings (2N3904, .01 uF, etc.). That

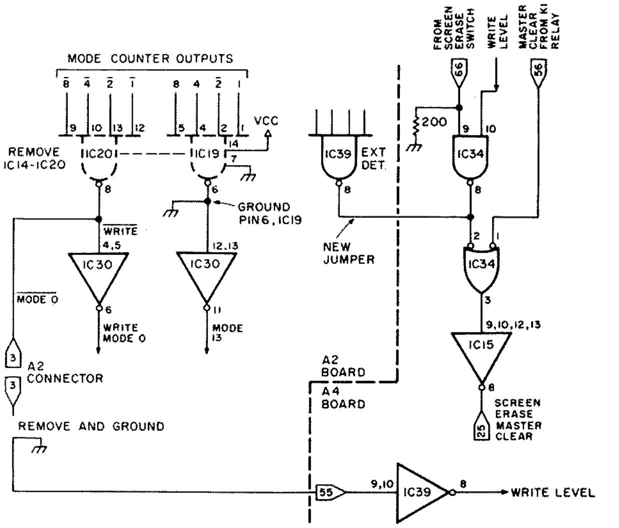

Fig. 1. Summary of modifications. Circuits for mode decoding and Screen Erase are shown before and after changes.

was important, because it told me that replacement parts for those boards would not be hard to find, and the type numbers indicated that the equipment was not very old. A card rack holding up to six cards was found inside the rear cover, but two cards were missing. That could present a problem, I thought, because the cards that were there had up to 48 ICs on them and none of the ICs had recognizable numbers. There were two muffin fans, a sturdy cabinet, and a healthy looking power supply. The spare parts turned out to be an extra matching cabinet (for a vector graphics display later??), a spare CRT and yoke (new), most of the power supply parts, and several spare boards (non-logic). A quality control tag inside the cabinet indicated assembly only three years previously! Encouraged, I dragged the thing to an ac

Photo 2. The mechanical keyboard was replaced by an electronic keyboard. The cursor and editing controls are on the right side of the control console.

outlet, plugged it in, and, with fear in the salesman's eyes, turned it on. After what seemed like hours, 1080 characters appeared on the screen ... all garbage ... but did light up and draw current, so I bought it.

During the following weeks, I must have disassembled and reassembled the thing four or five times, trying to uncover its secrets. I learned that it used a monoscope for character generation (*good grief!*). Imagine using a second special CRT to generate character video when a handful of ICs will do the same job! It also employed a magneto-strictive delay line memory (definitely not Altair bus compatible), which was no more than a long wire coiled up in a box. I had visions of trying to load it up on 80 meters as a compact antenna for my ham activities! The keyboard generated a 64 character ASCII subset with special characters for multiply (x), divide (÷), and ETX (end of text). It looked great but wouldn't work with two of the boards missing and the motor gone from the keyboard. I recognized my lack of mechanical aptitude and scrapped the old keyboard, building an electronic one to replace it. I used a keyboard that is widely advertised for around $20 and a KR-2376 keyboard ROM (see Photo 2). Since I didn't know which family of ICs I was dealing with in the terminal, I buffered the keyboard ROM with TTL, hooked it to the terminal, and applied the standard tests. No smoke, voltage levels okay, but no other response. After talking it up with many people, I located someone who had a 752 VDT working and borrowed his logic boards. It worked to some extent, but the characters were badly distorted. After replacing the video driver board with the new one from my spare parts, it worked perfectly!

I soon learned that the VDT operated only in the Screen Read mode. That is, the operator creates a message by pushing the Write key and typing the desired data. The ETX key must be the last character typed in. Editing can be done, as if off-line, using the editing keys I mentioned earlier. When finished, the XMT key must be pushed to transmit the data to the computer. Everything on the screen is transmitted, up to and including the ETX character. The VDT automatically inserts an STX (start of text) character at the beginning of the transmission. When transmission at 1200 baud is completed, the VDT switches to the receive mode, with the keyboard and function keys disabled. The computer may then reply, but must bracket its message between the STX and ETX characters also. When the VDT receives the ETX, it reverts to the Write mode, with the computer's reply on the screen and everything else erased.

At this point I was reasonably happy. After all, the only thing left to do was find my own logic boards to replace the ones I had borrowed and must return. I had considered the insane idea of duplicating the boards, but double-sided boards are tough enough without considering four layered boards (as these were). However, I reasoned, if I could decipher the logic family, I could simply wire-wrap the two boards I needed. After several iterations of sort and compare, I almost settled on DTL as the probable family. Vcc appeared always on pin 14 and ground on pin 7 (could be TTL). Vcc was set at +4.5 volts, a little low for TTL. Then, while trying to repair a bad connection I had created, I noticed that someone had mercifully installed an MC851P one-shot on the A21 filter board. DTL it is! To make a long story shorter, I succeeded in wire-wrapping the two boards using Motorola MC830/930 or equivalent ICs. The new boards just fit in the rack after trimming the wire-wrap pins on the sockets. My bargain terminal was working on its own for an investment of $250 and a lot of my time.

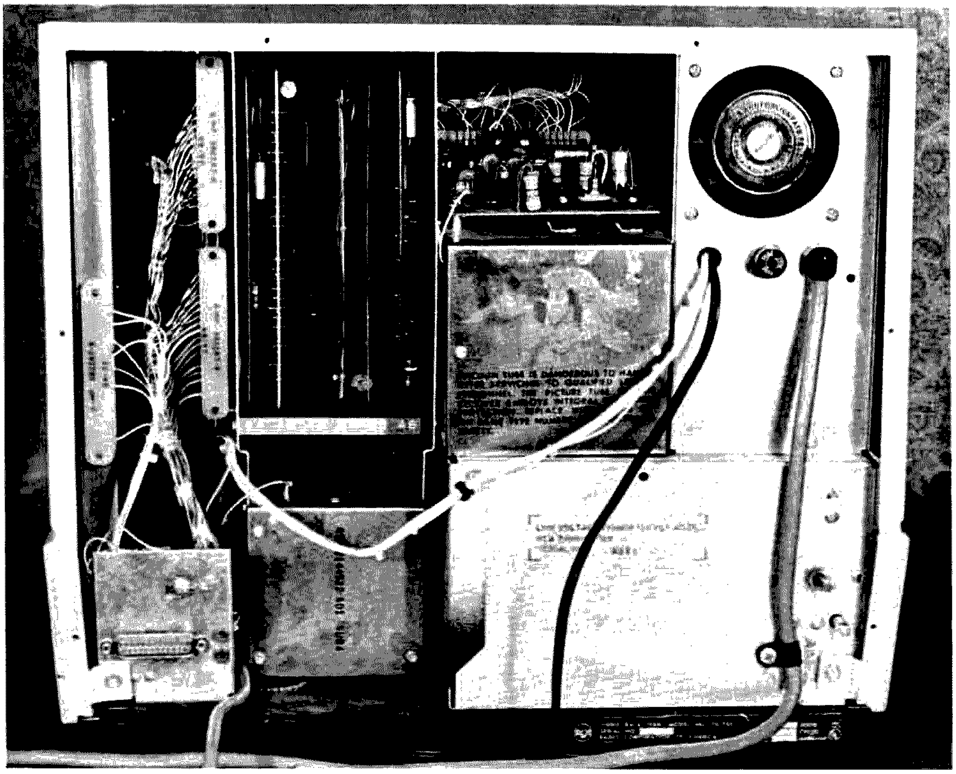

Photo 3. Rear view of the Video Data Terminal showing the logic card rack, RS-232 connector, and memory on the left. Power supply with integral fan is on the right.

Compatibility

Or was it? Yes, in part, but a working component does not make a working system. Having all data bracketed by STX and ETX became a sore point for me. Many of my programs required three characters from the VDT (STX, desired character, ETX). Also, the VDT always seemed to be in the wrong mode. There were two possible solutions to this problem: software adaptation or hardware modification. Software adaptation is cheaper for the hobbyist, so I tried that first. My input routine was written to grab at least two characters from the VDT before returning to the calling program, each time checking to see if an ETX had been received. If it was received, the program sent an STX to the terminal to put it into the receive mode. If ETX had not yet been received, more data was forthcoming from the ter-

minal. I found it best to never send ETX to the VDT, since that would switch it to the Write mode, and the possibility of losing the next computer output was very real. This scheme works very well and served me for some time. At least two weeks or more.

Not willing to leave well enough alone, I favored a hardware modification to the 752 to allow full duplex operation without having to deal with the STX and ETX characters. The criteria were that the VDT should always be ready to receive at 1200 baud, the cursor controls should always be enabled, the keyboard should provide parallel data directly to the computer, and there should be no requirement for the program to echo the keyboard to the display. In addition, I wanted the Screen Erase and Cursor Home functions to be under software control. It sounded like quite a task, but turned out to be a very simple modification.

Modifications

The logic cards are numbered A1 through A6 from left to right when facing the rear of the cabinet (see Photo 3). Remove A2, second from the left, and position it with the component side up and the edge connector to the right. Number the IC positions starting at the upper left. Positions with no ICs inserted are also numbered. You should end up with the ICs along the edge connector numbered as 4, 8, 12, etc., from top to bottom (see Photo 4). Now carefully remove IC14, IC15, IC16, IC17, IC18, IC19, and IC20. I found a solder sucker to be valuable here. If you too have wire-wrapped boards, simply unplug the ICs. These ICs decode which mode the terminal is in, and with them removed, it is in no mode at all. Next, solder a jumper wire between the holes where IC19 pin 6 and IC19 pin 7 were inserted. This grounds the $\overline{\text{Mode 13}}$ line and puts the terminal in the basic receive mode. You are done if you don't care about the other criteria I established. To enable the cursor controls and allow for direct keyboard entry to the display, remove the wire-wrap wire from pin 3 of the A2 connector (on the chassis) and connect it to ground. This modification enables the Write mode (with the Receive mode still active). Parallel data is taken directly from the keyboard, or from where the keyboard connects inside the VDT, on the A21 filter board. If you are using the mechanical keyboard, you will be able to bring out the Keyboard Strobe signal from the A3 board. Pin 44 is active low and pin 46 is active high.

If you want software control of the Screen Erase and Cursor Home functions, a less elegant modification can be made. Remove IC39 from the A2 board and bend pin 8 of the IC up so that it will no longer make contact with the board. Put the IC back into position 39 where it was. Run a jumper wire from pin 8 of IC39 (the one just bent) over to either pin 2 or pin 8 of IC34 on the A4 board. Use a connector of some sort so that the two boards may be easily separated later. This change creates a wire-ored connection between the Screen Erase function and the ETX detector. Now each time ETX is received by the terminal, the screen will be erased and the cursor will home to the upper left-hand corner. The VDT accomplishes this by zeroing the delay line memory. This takes one frame time, or 16.7 milliseconds. A software delay must be provided to prevent the computer from sending more data during the erase time. These modifications are summarized in Fig. 1.

Improvements

The modifications just described will prohibit Screen Read operation. To retain that feature, a more elaborate scheme could be used which gates the decoding ICs on the A2 board using a single switch to choose the type of operation you want. A UART could be added to the keyboard to provide serial transmission in both directions.

Conclusion

The RCA 752, although ancient by today's standards and techniques, comes available to the hobbyist for just that reason. Yet it can provide a low cost terminal with features that demand a very high premium if purchased new. If you come across one, you might also look for some of the other options available with it (and similar surplus terminals). Those options include the capability of plugging in a printer for hard copy direct from the screen, and a variable screen format which provides for almost any combination of lines and characters/line which total 1080 characters.

My thanks to Kurt Lessor and Andy Demland for their help in the rejuvenation of my terminal. Incidentally, I found a Z-80 Digital Group system under the Christmas tree this year. It uses a TV-based philosophy and I saw a very nice commercial monitor at the surplus store . . . ■

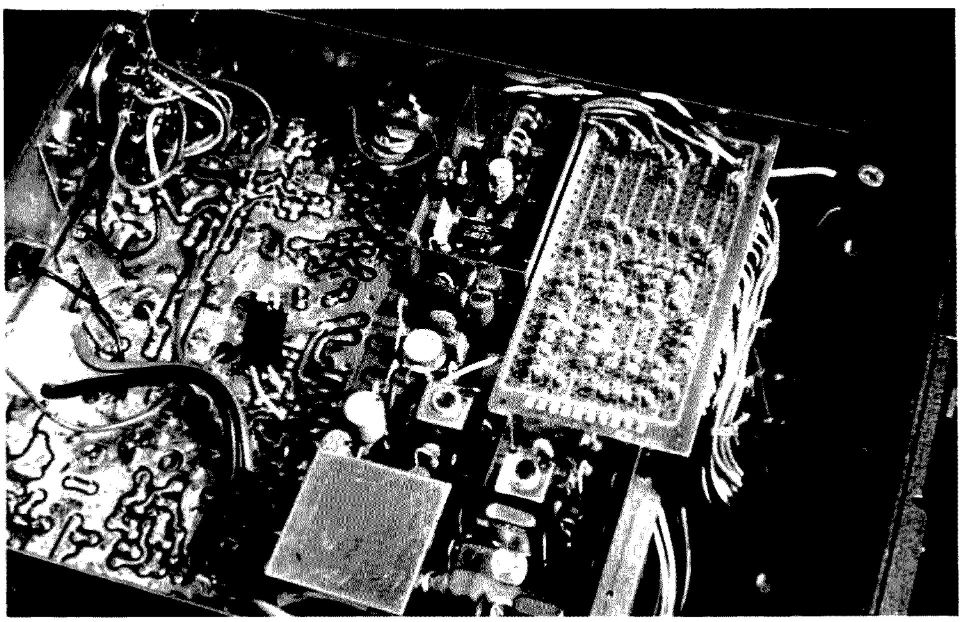
More Channels for the IC-22S

-- using dip switches



Interior view of IC-22S showing wires added to matrix board and soldered to accessory socket. Note wires are kept close to edge and taped together for a neat installation.

Icom's introduction of the 22S has ended the day of waiting for the mailman to bring those crystals for a particular frequency — that is, if you happen to own one of these little marvels.

The very same day I purchased my rig from the local dealer, I had completely programmed the matrix board for 22 channels by nightfall. For those of you that have not seen, heard, or owned the 22S, let me explain. Switching diodes are soldered to a very small matrix board which is plugged into the transceiver. A chart in the instruction manual indicates placement of the diodes for 128 frequency combinations, with 15 kHz spacing. A channel switch allows you to select one of 23 programmed

Fig. 1. Matrix board of IC-22S.

146.34 MHz	X						X	
147.18 MHz	X		X	X	X		X	

Fig. 2.

frequencies. I will not go into detail how this works; the important thing is, one need never purchase another crystal.

This brings us to the reason for this article. With 22 channels already programmed, I had only room left for one channel, which I had decided to add at some future date. I began looking at additional frequencies that I could program into the 22S, and discovered there were quite a few. Once I picked the final unprogrammed frequency and soldered in the diodes, I was finished. I would really be in worse shape than a crystal rig owner. He could change frequencies just by pulling a crystal out and plugging another in. To change a frequency in the 22S entailed the removal of a diode or two, and adding others into their proper positions. I found, while soldering the diodes to the board, that to make a mistake and have to remove one required three hands. The board itself would not take this type of abuse too many times.

At this point I decided there should be some way to switch those diodes in and out externally. After all, there are 128 selections available, and I might as well be able to take advantage of their use. One reason I had not programmed channel 23 was the deletion of a wire from the channel selector switch to the 23rd position on the matrix board. For some unknown reason, Icom overlooked this. There was a blank lug on the channel selector switch, so I ran a small stranded wire, similar to the others, from the blank lug to the 23rd position on the board. Channel 23 became the first white dot after channel 22. This was also to be the channel I would be able to program externally, by some type of switching arrangement.

By careful inspection of the matrix board and the schematic, I had a working idea of the design. The anode of each diode on a specific channel has 9 volts applied to it by selection of the channel switch. Their anodes are also common to each other. The cathodes of the diodes are soldered into selected holes marked D_0 to D_7. By simple mathematics, I concluded it would take 9 wires to run from the board to a switching arrangement. The accessory socket just happens to have 9 lugs to run the 9 wires. One of these lugs has a blue wire soldered to it, which is a metering point for the discriminator. Another lug is grounded with a .01 capacitor soldered between the blue

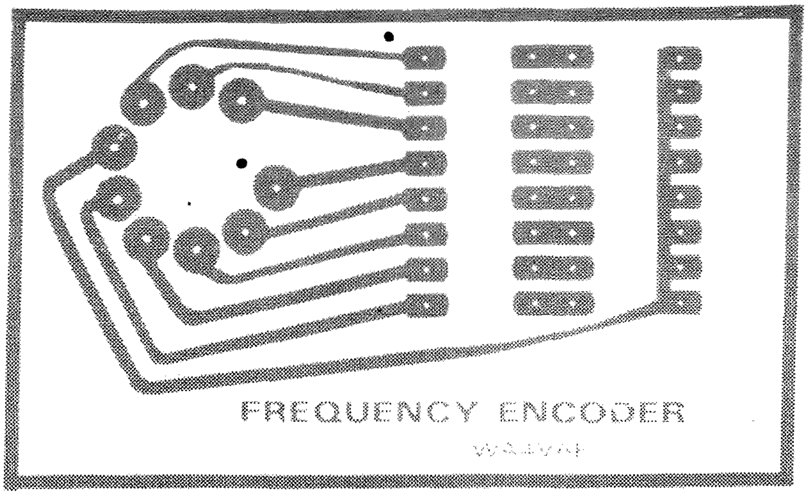

Fig. 3. Foil side of PC board shown actual size.

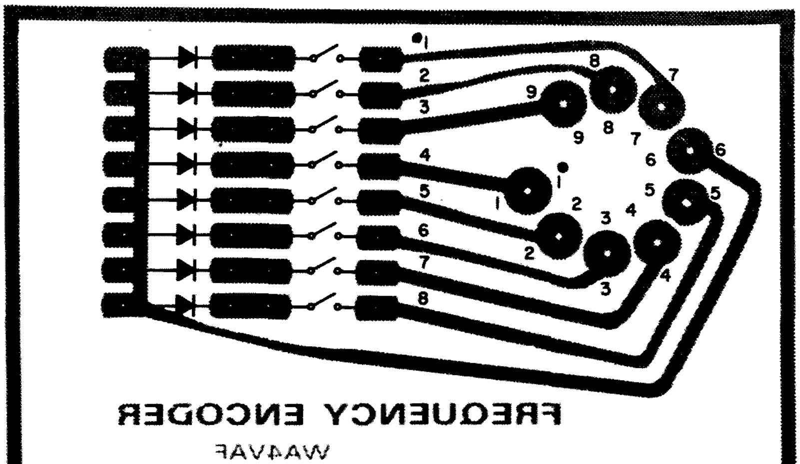

Fig. 4. Parts placement. Parts side of PC board with switches. Note pin 6 is the common anode lug, while the other lugs have the wires on accessory socket going to the matrix board soldered to them to allow the board to be positioned parallel to the 22S. The prototype protruded downward in a precarious position. Also note that the plug is soldered onto the foil side of the board.

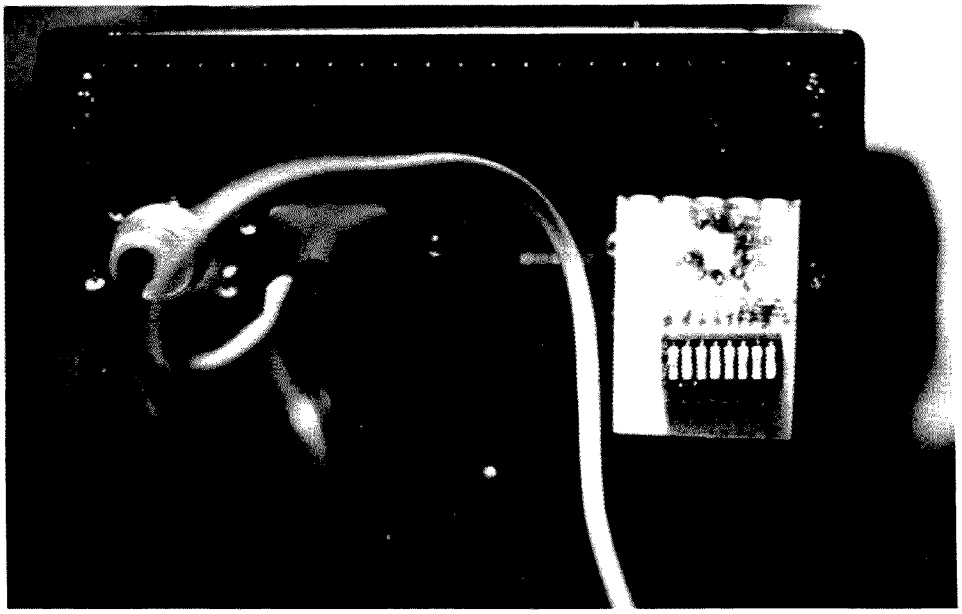

Prototype board plugged into accessory socket of IC-22S. The author still uses this original on trips. The new board is a snugger fit, but the accessory socket had to be wired differently since the board was rotated to the left by 90 degrees.

wire and the ground lug. These were removed from the socket. The blue wire was rolled up and taped aside, while the capacitor was saved and the ground connection removed from the other lug. This allowed me to return the rig to the original condition at any time.

At this stage I ran a wire from the common anode connection of channel 23 of the matrix board to pin 6 on the accessory socket. At each diode position where the cathodes were normally connected (numbered D_0, D_1, D_2 on to D_7; see Fig. 1), I soldered a small wire and ran these to the socket and soldered them to lugs 1 to 8.

Now all I needed was external switching that would permit me to switch each diode in or out of the circuit. I ruled out some sort of minibox with toggle switches as being too bulky and also distracting from the clean-cut looking design of the 22S.

Sometime back, while thumbing through *73* looking over the ads in the I/O section, I came across a 16 pin mini-dip rocker switch. I decided this would be my switching device. Can't get much smaller than that. Since I had to plug the accessory plug into the rear socket, I proceeded to design a PC board which would be soldered directly to the pins

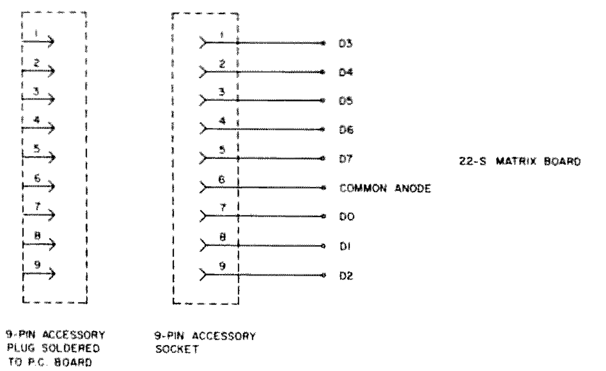

Fig. 5. Connections from 9 pin accessory socket to channel 23 on 22S matrix board.

on the rear of the plug. Just unscrew the cap on the plug and discard. I came up with a very small board which, when soldered to the plug along with the mini-dip rocker switch and 8 diodes, made a neat package that allowed me to plug the whole thing into the IC-22S.

The mini-dip rocker switch interconnects the plug and the 8 diodes. All the anodes run directly to pin 6. The cathodes can be switched in or out, or off and on, as the rocker switches read – thus, instant programming at the flip of a dip switch. Just look up the frequency on the chart in the instruction manual, and push the switches on or off with the tip of a ballpoint pen. The scheme works as if they were soldered to the matrix board itself, and I have found no undesired effects.

One word of caution: Don't try to do this while driving on the freeway. I usually throw the thing into the glove compartment for trips out of town or a vacation. The night before, I check my road map along with the *73 Repeater Atlas*. If a set of strange repeater frequencies come up I'd like to be able to work, out comes the little board. With the aid of the programming manual, in less than a minute I'm ready for that heretofore unaccessible repeater. The dip switch is numbered 1 to 8. I knew I'd have to remember the program is D_0 to D_7, or relabel the program D_1 to D_8. This is what I did; I had it reduced about ¼ the size of the original and then laminated.

What do you do if you lose your programming chart or forget it? Here is a simple formula that will give you the diode placement or switching input for the mini-dip switch:

$$N = \frac{(f - 146.010)}{.015} + 108$$

where N = Number, f = frequency desired in MHz.

Example: frequency desired (f) = 146.34.

$$N = \frac{(146.34 - 146.010)}{.015} + 108$$

$$N = \frac{.33}{.015} + 108$$

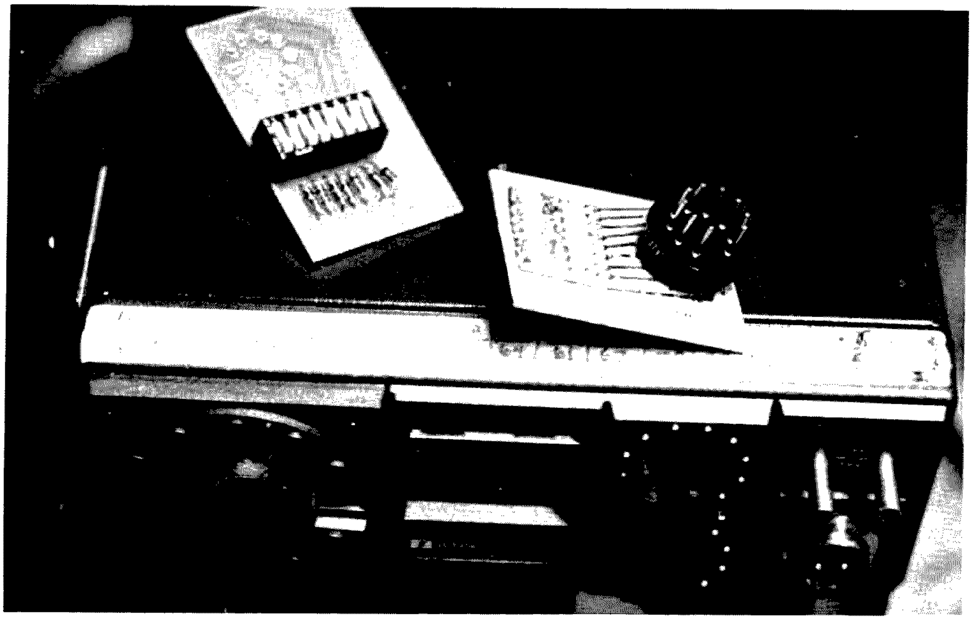
$$N = 22 + 108$$

$$N = 130$$

The programming table refers to this number under total "N". If you look at 130 in your manual, you will see it is indeed 146.34. But how does this number help in positioning of the diodes or, in our case, the switching of the external programmer? If you will notice the matrix board to which the diodes are soldered, you will see the numbers below each diode position. Starting with D_7, the number below it is 128, while D_6 is 64 and D_5 is 32. We can see at once each number is halved. You should be able to remember this; if not, make a chart as shown in Fig. 2, used for the example above.

Recall that earlier we received an answer of 130 for the frequency of 146.34. To obtain the position of each switch, simply find the largest number on the chart that will divide into our number of

130 (128 in this case). Put an X under D_7 or switch 8 depending on how you make up your chart. We now find that we have a remainder of 2. Find the next highest number on the chart that will divide into 2. Position D_1 or switch 2 will be found under the number of 2, with no remainder. Put an X at this position. When you have divided the remainder by the largest number each time, and finally have no remainder, you have completed the program. Be sure to mark an X in each position you used that number. Let's take a more complex example to see what happens when the number is too small to be divided by one of the 8 numbers on the chart.



External frequency programming boards on IC-22S. Board on right is prototype. Board at left is the new design which fits rear of the 22S a bit snugger. Note plug is soldered to foil side of boards.

Example: frequency desired (f) = 147.180 MHz.

$$N = \frac{(147.180 - 146.010)}{.015} + 108$$

$$N = \frac{1.170}{.015} + 108$$

$$N = 78 + 108$$

$$N = 186$$

Therefore: 186÷128=1 with a remainder of 58 (X at Position D_7). 58 cannot be divided by 64 so leave position D_6 blank. 58 can be divided by 32, so put an X at position D_5. We now have a remainder of 26. 26 can be divided by 16, so put an X at D_4. The remainder is now 10, which can be divided by 8. Put an X at position D_3. 4 will not divide into our remainder of 2, so leave D_2 blank. We do put an X at position D_1, since 2 will divide by 2. Since we have no remainder, D_0 is also left blank, and that completes the program for this particular frequency. All that's left to do now is switch the mini-dip rocker switches to the on position under the numbers where you have placed an X.

I carry a copy of this formula in my billfold and, after several moments of calculation, I have the correct switching inputs. This can be explained in computer terminology, but this method keeps it simple and allows the average ham with no background of this type to find the switch positions without cluttering his mind with computer logic. That's what the I/O section is for.

Back to the external switching board. Very few parts are required. The accessory plug comes with the 22S, as well as the diodes; just remember to save 8 of them. If you need more, a diode such as the 1N914 can be found from several mail-order houses in *73* at real bargains. The same goes for the mini-dip switch too, although I picked several of these up at a local hamfest at a buck apiece. Parts placement is shown in Fig. 4. This final layout of the board allowed a closer fit to the rig. You can outboard the thing into a box as I mentioned earlier, but for a compact neat switching circuit, you will probably want to make a board.

I've been using the prototype board I made for several months now. It certainly beats carrying a soldering iron around with you, and it's like having a crystal pack with 128 crystals at your disposal. When I want to change frequencies, all I do is "flip my dip." ■

Note: A drilled board complete with instructions can be obtained from the author or from Bryant Electronics, 1915 E. Independence Blvd., Charlotte NC 28205, for $4 ppd.

Try a Scandie-Talkie

-- build a scanning HT

One of the most all-time popular and universally utilized amateur radio transceivers is the two meter FM handie-talkie. Proudly displayed by their owners, they appear at hamfests, flea markets, walkathons, parades, and other public service events as the easiest, most reliable form of quick communication. More and more mobile ops use them so they can take their rigs along from their cars, preventing theft of a car-mounted FM transceiver. Dangling one from your belt has the added advantage of imbuing you with instant high-class ham radio social status. Anyway, they're great fun. But the problem for the uninitiated has always been trying to get one of your own for something less than the minor fortune required for most of these gems.

Photo 1. Scandie-talkie and obviously gleeful author in dorm room ham shack.

This article explains how easy it is to home brew/kitbash your own HT, with features of no other talkie available anywhere, and at a low cost. Its features are:

Four channel scanning receiver, one channel (easily expanded) transmitter. The scanning feature lets you monitor several repeaters at once, or a mix of repeater and simplex channels. Don't miss a call from a friend because you couldn't listen to more than one frequency; now you can "time-share" your channel snooping! Of course, you can always switch to the manual mode or lock out channels you don't want to scan at any time.

First-class performance, with highly selective sensitive receiver and 1 Watt transmitter. The receiver section is the most important part of any rig, and this one has big advantages over using a cheapie tunable police band monitor as the receive section of the HT. Two rf stages, double conversion, two ceramic i-f filters, and crystal-controlled. No mickey-mouse compromises.

Easy-to-get main parts; the receiver is ready-made, the transmitter is an easily built kit.

Lower cost than the least expensive commercial HT! Even if you bought everything new, it would only come to about $135 (and don't forget this one *scans*). If you're not too impatient and like to attend flea markets or auctions, you can build it for about $50-75.

Hand-held designed so that the receiver alone can be removed in seconds, its own battery pack snapped in, and used as a pocket scanning monitor.

External mike built in; no need to go to extra expense since everyone uses one anyway. Push-to-talk, of course.

The Receiver Section

The receiver I used for my scandie-talkie is a Radio Shack Realistic (registered trademark) PRO-5 UHF pocket scanner, which I converted to two meters. Radio Shack also manufactures a PRO-4A VHF-high band only pocket scanner, as well as a PRO-6 VHF-high/low band model. Other pocket receivers are made by Pace, Johnson, and several scanner manufacturers. Alternately, Tempo makes a new tiny pocket scanning receiver, and a 12 channel fixed receiver which could be used. All are excellent receivers, and when tuned up as outlined below, compare with the best commercial HT receiver. Their selectivity alone makes it worth the nominal extra cost over a tunable public service

Photo 2. Note classy poster backdrop, also collapsible whip antenna stuck into antenna jack of HT.

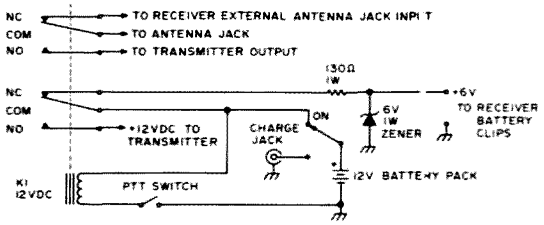

Fig. 1. Hand-held wiring schematic, showing relay hookups and receiver 6 V regulator wiring.

band receiver – a PSB rig just won't cut it unless there's only *one* very strong local repeater and you don't like simplex operation!

I bought my well-used scanner for $15. I've seen them go for $30-45 at flea markets and auctions, if you want to wait for one. You'll save a good deal of cash if you do wait – particularly if you can bargain person-to-person at a flea market table and not get stuck bidding away your savings in an auction. Of course, you can buy a brand new shiny one at Radio Shack almost anywhere. The modifications I describe here won't lower the resale value in any way, nor destroy the rig's appearance. All can be restored to the original.

If you get a PRO-4A, 5, or 6, the first step is to remove the batteries in their little snap-in case. Save this case because you can use it when you want separate monitor-only operation. Remove the two screws at the bottom of the case, squeeze the sides of the case half (with the speaker grill on it) near the crystal socket cover, and pull the bottom of the case back and away. There's a screw in the middle of the PC board, and when you remove it, you can separate the other half of the case from the board.

Look at Photo 5 and notice the small PC board mounted on top of the larger one. That smaller board has the front-end and mixer which determines the band for which the receiver was designed. The larger PC board has the i-fs, filters, oscillators, and scanning/audio/squelch circuits – they're essentially the same for all three models.

Of course, the VHF-high and VHF-high/low band models, the PRO-4A and the PRO-6, don't need conversion, only tuning to optimize their two meter performance. More on this later. To convert the UHF PRO-5 receiver to two meters, all you have to do is make some air-wound coils to replace the three UHF hairpin coils on the front-end/mixer board. You can see the ones I made in the photo, on the small board. They are 6 turns, #22 solid tinned wire, 5/16" long and ¼" in diameter each. To replace the originals with these, use a solder sucker and schlumpf up the solder on the pins which hold the small board to the larger one. Gently pry the two boards apart. Now use the solder sucker to remove the solder from the ends of the three UHF coils, and also from the tap wires where they connect to the coils. Leave the tap wires in the board. Now solder in the new coils, and put the taps at about the same relative position on these coils as on the UHF ones (e.g., if the UHF tap was about ¼ of the way up from one end of the total winding, the VHF tap position would also be ¼ way up the total winding). Save the UHF coils in case you ever want to put the receiver back on that band. Clean, remount, and solder the front-end/mixer board back on the main PC board, and you're finished with this simple conversion.

Once you've got the VHF coils in place, tuning up the receiver is just like tuning up the VHF-high and VHF-high/low models – tweaking three trimmers and two coil slugs. Tuning all three models is strongly recommended for maximum performance on two meters, since all these radios come from the factory stagger-tuned for a broad response from the 148-170 MHz. This leads to poor sensitivity on 146 MHz and sometimes severe image and cross-talk problems. If you maximize the front-end response for on a frequency near midband in the FM segment of two meters, all those bad responses disappear and the sensitivity is much enhanced.

I tuned my receiver by inserting a 2 meter crystal, listening to a weak signal, and peaking the three trimmers on the front-end board for maximum response. Use an insulated tool for this! Then I touched up the i-f input coil, shown on the photo next to the front-end board. With the weak signal input removed, adjust the oscillator coil (near the crystals) for maximum noise. Repeat the procedure a few times – be sure to keep the input signal well below full noise quieting – and optimize the front-end trimmers as a last step. Now you've got a first-quality selective scanner with a sensitivity of about 0.5 uV. By the way, Radio Shack has avail-

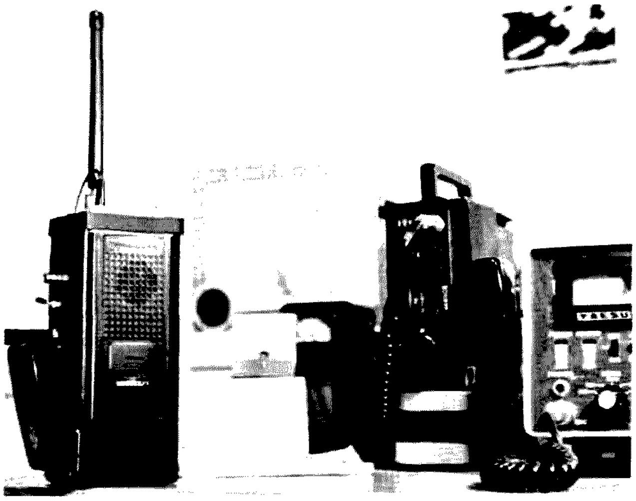

Photo 3. Close-up of talkie with author's other ham gonk. Rubber ducky installed; microphone on its bracket.

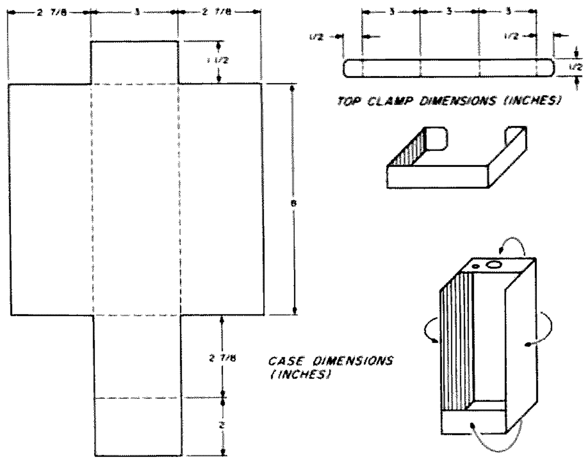

Fig. 2. Aluminum case, clamp dimensions, and fold lines.

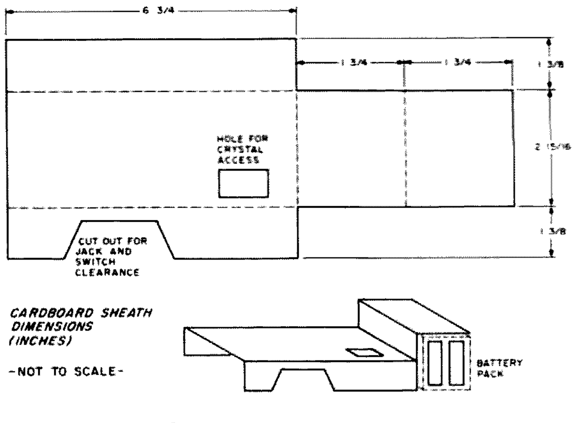

Fig. 3. Cardboard sheath dimensions and folding guide.

able on order service manuals for the PRO series; these are about $2 each. The one for the PRO-5 is #20-169.

Hint: A good weak-signal source is a cheapie tunable VHF-high band police receiver. Tune it to about 157 MHz and listen for its oscillator (at about 146 MHz) on the scanner. Orient the two for the signal level needed. Be sure to tune the police radio carefully – these pocket scanners are very selective and you might swish the oscillator right through their passband.

Since you'll need crystals for this gem, Radio Shack can supply them (fast!) for $6 a throw. If they're not in stock at the store for the frequencies you want, they will have them sent within a week. However, regular monitor crystals work fine (3rd overtone, approximately 45 MHz output) and are usually cheaper. Tufts Radio carries this type for $4.50. I have an Icom IC-22A and alas! its receiver crystals don't work. The 22A uses 15 MHz fundamental crystals and they will oscillate in the scanner, but in a third-overtone mode, about 30 to 60 kHz off their marked frequency! Oh, well, monitor crystals are cheap and easy to get . . .

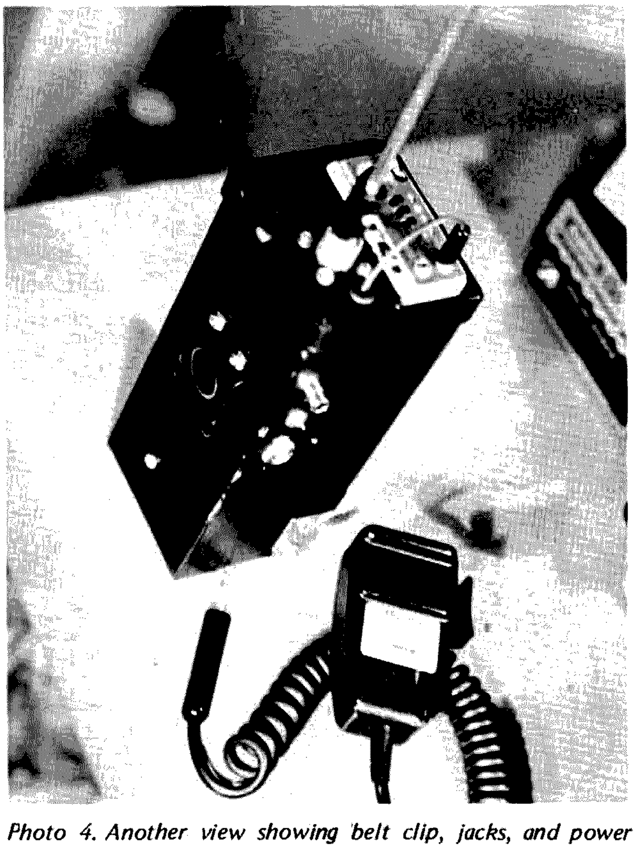

Photo 4. Another view showing belt clip, jacks, and power switch.

The Transmitter

The model TX-144 transmitter can be purchased in kit form from VHF Engineering, 320 Water Street, Binghamton, New York 13092. It is well designed, easy to build, costs only $29.95, and puts out a peppy, well-modulated 1 Watt signal. Mine is mounted with brass brackets that hold it about 1/16" off the HT case, soldered to each end of the PC board. The transmitter will take any low-impedance (500 Ohms) microphone, including a carbon mike, which is what I used. Follow the directions with the kit to see how to hook up any variety of microphone you may have handy.

By the way, the carbon mike you see in the photos is a Telex TEL-66C noise-cancelling affair, the classy kind you see private pilots using. Mine, in fact, did come from a well-worn aircraft. It's ideal for a handie-talkie because it tends to reject wind, street, or other noises normally present in portable operations. It's also quite lightweight.

Crystalling up the transmitter is a bit more simple than the receiver. Icom crystals work, as do any crystals in the 18 MHz range. These are available nearly anywhere. You may find, as I did, that the capacitor in parallel with the TX-144's crystal trimmer is a bit too large. I changed it to a 12 pF ceramic trimmer (it was 22 pF fixed silver mica), and now all the crystals tune in on frequency when the main trimmer is at half-mesh.

I have used this single-channel version for months now, but should you want more transmit channel capability (you already have 4 receive channels), it's a simple matter to add a few more crystal sockets. Mount a micro "PC board" size rotary switch on the case underneath the mike jack. There is plenty of room, as you can see in Photo 6.

Wiring and Switching

Fig. 1 gives the wiring schematic for the transmitter-receiver. The relay performs two functions – switches the antenna from the receiver to the transmitter, and similarly switches the +12 V dc line between the two. This relay is a tiny little 12 V affair I found at a flea market, Potter and Brumfield HP-4038. Most any kind of small 12 volt DPDT relay should work. It should

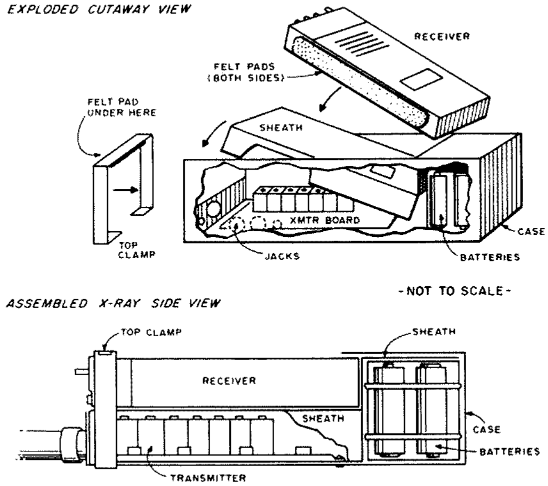

Fig. 4. Assembly sketches.

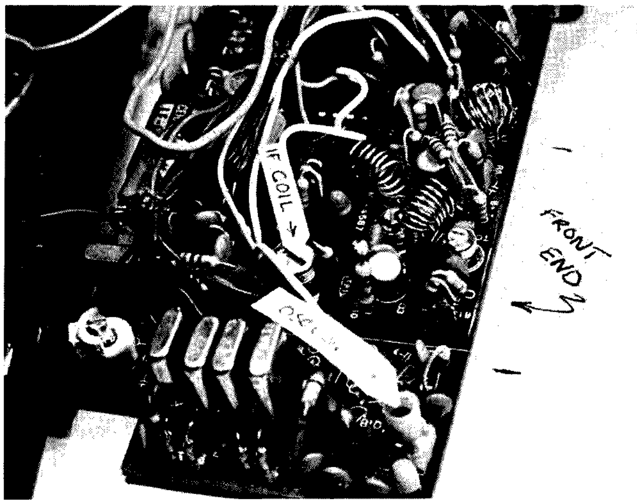

Photo 5. Inside PRO-5 receiver, showing new front-end coils and main PC board alignment points.

be mounted as close to the antenna jack and transmitter power output port as possible. Short leads minimize losses! The receiver signal is routed through a short length of RG-174/U subminiature coax to a mini phone plug which connects into the external antenna jack of the scanner. It goes through a grommet where it passes through the metal case. The photos reveal all.

The scanning receiver uses 6 V dc while the transmitter runs on 12 V. Rather than having awkward plugs sticking out all over the thing, or running the receiver off its own batteries and having to use a complicated relay, I made a 6 V regulator built around two insulated mini alligator clips. The clips go on the receiver's battery contacts and the zener diode and resistor fit neatly in the vacant battery compartment. Now everything in the HT runs off 12 V. Then, if you ever want to use the receiver separately, you just unclip the regulator and snap in the original battery pack. Versatility!

Don't forget to include the charging jack for the handheld's batteries. It's switched in when you turn the rig off, and also provides direct access to the 12 V supply at that jack so you can run other projects off the batteries without taking them out of the case.

The Case – Boxing It Up

The case is made from a sheet of aluminum 1/16" thick. Fig. 2 shows the dimensions and folding lines. It's not too difficult to bend with a bench vise and a good supply of hardwood blocks. Use a mallet and cloth to avoid hammermarks and vise teethmarks.

The top lip is drilled and filed out to accept the SO-239 antenna jack. Or, you can mount a BNC jack there instead. Don't forget a hole for the receiver's antenna coax, big enough so a grommet will fit there. The little clamp-bracket shown slips over the case and holds the receiver's top section in place, the bottom of the receiver being held by the case's battery holder lip.

Looking down the case, the charge/12 V jack is on the left side at the top rear, then the power/charge switch, and finally the microphone jack. The microphone holder bracket is mounted at the lower front of the left side. Be sure you saved the belt clip from the pocket scanner – mount this at the rear of the case so you can hang the rig from your belt or anywhere else you care to clip it.

Figs. 3 and 4 and Photo 9 show the way the whole thing is put together. The batteries are at the bottom; jacks, wiring and transmitter are mounted at the back of the case; and then the whole thing is covered with a cardboard sheath so the receiver can set on top. Works great. Make a hole in the cardboard to get access to the transmit trimmer and crystal, and slip another thin sheet of cardstock over it so the receiver's regulator wiring doesn't get into the transmitter through the hole. The receiver is pressed into the case with heavy felt placed at either side of its cabinet, then the top clamp is slipped over the whole works. The top clamp also has some felt at its inside front, so that the receiver is firmly cradled into place with the thick felt. The result is a rugged mar-free compact

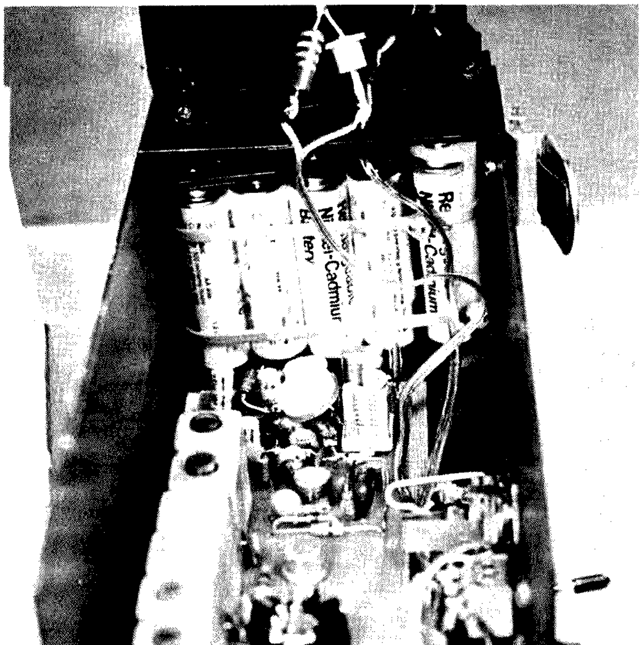

Photo 6. Cardboard sheath removed, looking down into battery compartment. Notice the 6 V regulator zener and resistor clipped inside receiver.

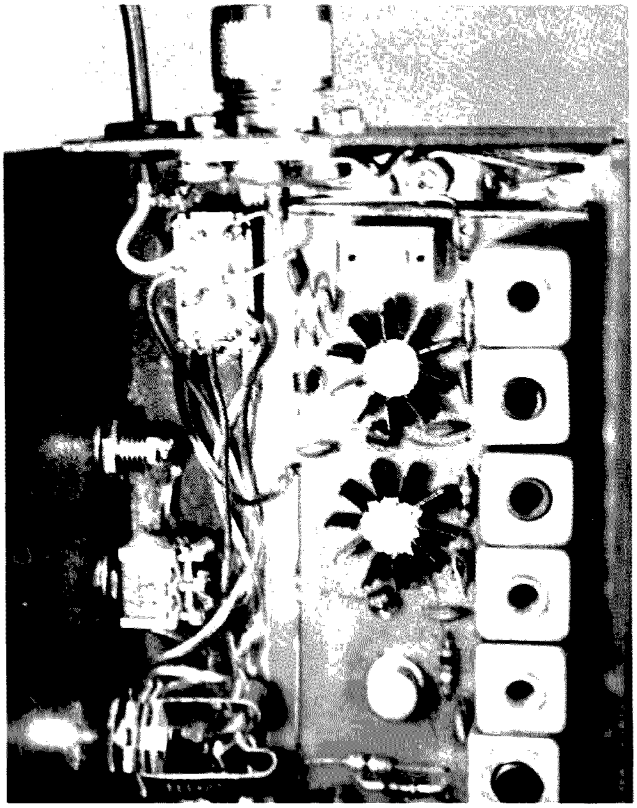

Photo 7. Close-up of the business end of the HT, showing the relay wiring.

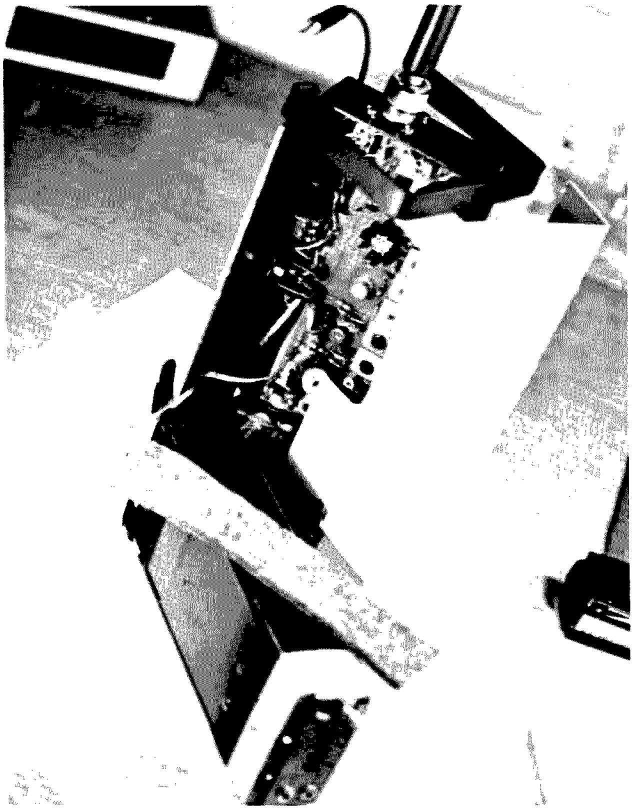

Photo 8. Case, sheath, clamp, receiver, and felt ready to go together.

unit.

Batteries

The battery choice is pretty much left to the builder, but I strongly recommend using nicads instead of carbon-zincs. The design leaves room for the 10 nicads I've lashed together with cable ties, as shown in the photos and figures. The cardboard sheath for the rest of the transmitter/power circuits also extends to cover the top of the batteries so their power connectors (made from the tops of old 9 V batteries) won't short out against the metal case.

Results and Conclusion

This HT is no toy, nor does it involve any compromises. Its performance emphasizes this over and over again. It hears 'em all and talks up there with the higher power rigs.

I've had many hams ask me if the scandie-talkie was commercially built. It always gets much interest wherever I go, particularly with the pretty red blinking LEDs scanning across the top attracting attention. I've had a great deal of fun using it for quick and reliable portable communications. I never miss a call with that scanner going!

Build this HT and join the fun of portable operation with a professional looking, sounding, and performing rig. And this two meter talkie does what no other hand-held does — it scans! ■

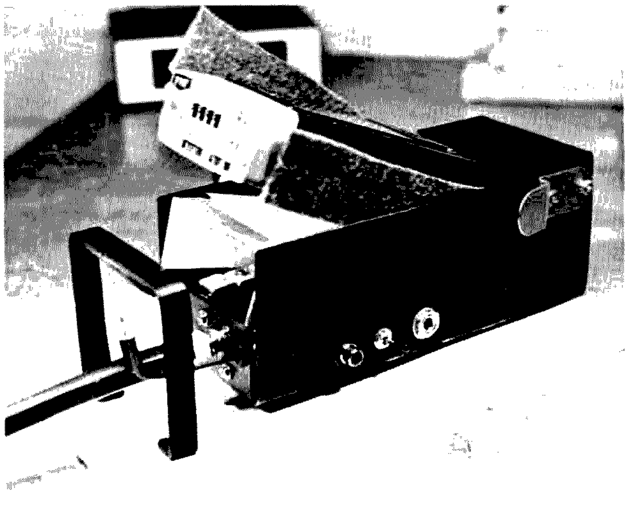

Photo 9. Nearly assembled . . .

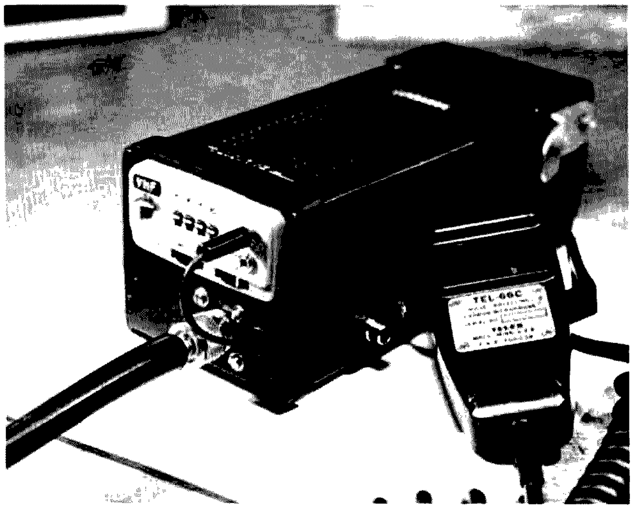

Photo 10. Presto! A super HT!

Current-Saver Counter Display

-- multiplex those LEDs!

Probably one of the greatest difficulties in building a counter or anything else that has a digital display is providing the large amount of current necessary to run the display and drivers. The easiest way to minimize this problem is to turn on only one digit at a time in a sequential fashion at a rate fast enough to eliminate flicker. If the duty cycle is low enough (ON time small in relation to OFF time), no current limiting resistors are needed in series with the digit segments. Without series resistors, there is less power wasted in heat, so power requirements are less.

Back in the December, 1976, *73* (p. 140), WA1UFE wrote an article describing (among other things) how he reduced the total current requirements of the LED display in his counter by sequentially strobing the individual display digits. His circuit is shown in Fig. 1. A 7492 binary counter (or a 7490 decade counter with no feedback) connected as a divide by 10 counter is continuously clocked by a 1 kHz signal from his counter time base. Each of the 10 counter states is decoded by a 7442 1 of 10 decoder and used to turn on a PNP switch transistor connected in series with the anode of each 7 segment LED digit. This results in each digit being turned on for 10 per cent of the time at a 100 Hz rate. Notice that there are no dropping resistors in the circuit. The only limits to current flow are the switching transistors, the driver IC, and the LEDs themselves. This allows most of the supply voltage to be dropped across the LED resulting in excellent efficiency.

Well, all this is good, but as far as I'm concerned it doesn't go quite far enough. If the LED display is the most power hungry component in a counter, its drivers (7447) come in a good second. Each one of those little beasts consumes at least 265 mW. (In comparison, a fully lighted 7 segment display dissipates around 420 mW, a 7490 about 160 mW, and a 7475 approximately 160 mW.) With eight 7447s driving eight digits (as in the WA1UFE counter) that's a total of at least 2.1 Watts

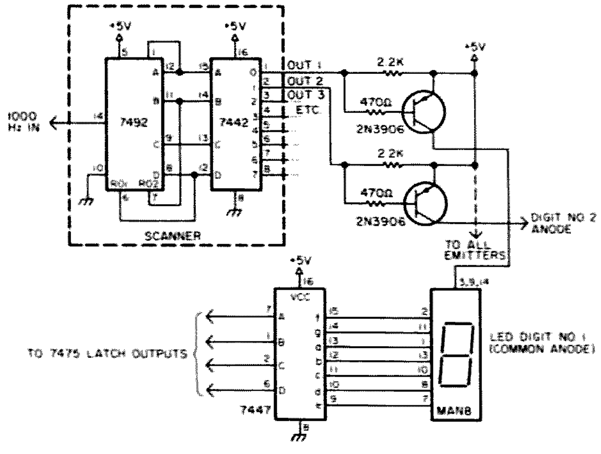

Fig. 1. WA1UFE display strobe.

(424 mA at 5 V). That turns out to be a fairly large contribution toward heating your shack (at least for a solid state device!).

So what can be done about it? There has to be some way to tell the LED which segments to display for which numeral. Ah-ha! he says. Since, when strobing, only one digit is on at a time, why not decode the 7 segment drive one digit at a time? This way you can be rid of the power load of all but one decoder/driver. Again, in the case of the WA1UFE counter, this would reduce the driver power requirements by a factor of 8. Following are two ways this could be done. The first is for the person who has already constructed a display system and doesn't feel like tearing it down and starting over. The second is for new designs and has the added advantage of being less expensive — only one 7447 is needed for the entire display.

The system for the existing display is merely a modification of display strobing. When a digit has been turned off by the strobe circuitry (which is 90 per cent of the time), its driver is just sitting there twiddling its open collector outputs. So why not turn it off too? This can be done by switching the 7447 Vcc in the same manner as was done for the LED anodes (see Fig. 2). If you are already strobing your digits, the driver as well as the digit can be strobed by reconnecting the PNP switching transistors to the individual 7447 Vcc pins. The LED anodes are then connected directly to the 5 volt bus. If you feel the display is too bright, an easy way to halve the brightness is to connect pin 4 of the 7447 (blanking input — called the BI/RBO node in the literature) to the 1 kHz signal that drives the strobe counter. Whenever this signal is low (and it's low half the time that any digit is on) the 7447 output is blanked, resulting in a 5 per cent (rather than 10 per cent) duty cycle. As shown in the schematic, the line driving the blanking inputs should be buffered by 7404 inverters since the BI/RBO node represents a load three times that of a normal TTL input (now why did they go and do that?). One inverter should be capable of driving three blanking inputs. Three buffers (inverters) are needed to drive the eight digits of the counter. Using this circuit with a MAN 1 display, the average segment current is about 8 mA (5 per cent duty cycle) giving brightness sufficient for a brightly lit room. With no signal driving the blanking input, segment current is 16 mA average and results in a very bright display.

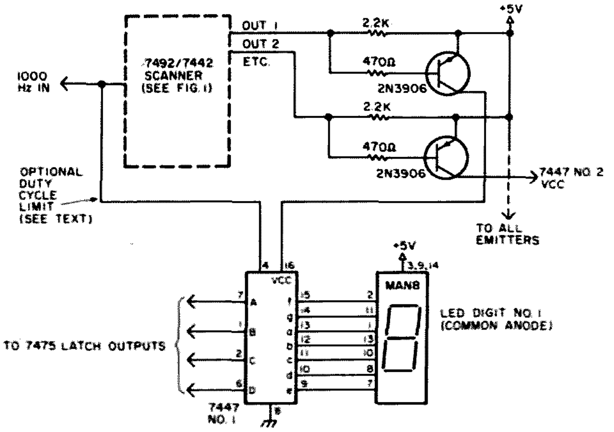

Fig. 2. Display and driver strobe.

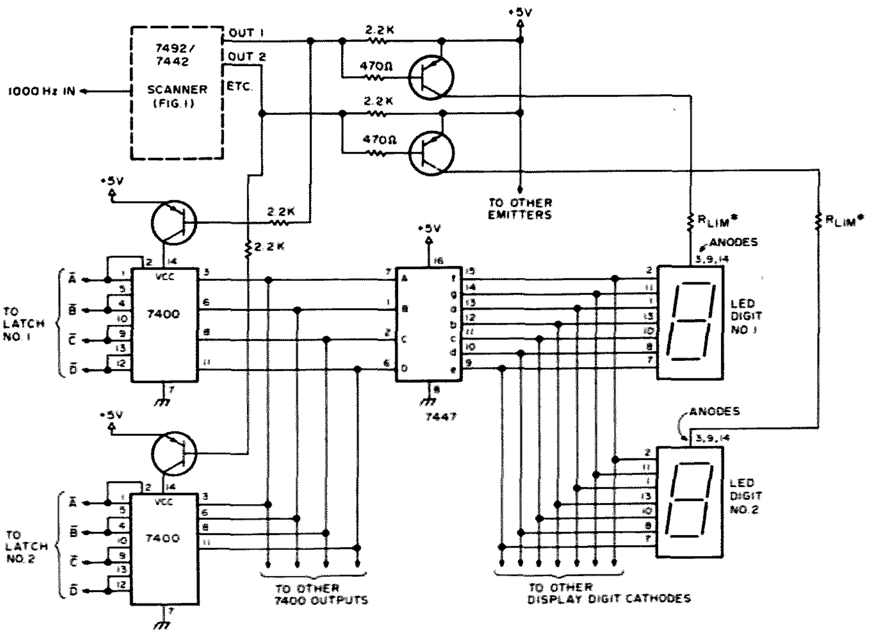
Starting from Scratch

This section is *not* required reading unless a) you enjoy modifying projects that are already working fine, b) you think it's time to start a new design, c) you wonder when the heck I'm going to say something about multiplexing, or d) you want to put off taking out the garbage for a few more minutes. A little thought about the last described circuit shows that since only one 7447 is used at a time, only one should be necessary for the entire system! All that is needed is a way to switch the 7447 to each BCD output and each 7 segment LED in sequence. This switching system (called a multiplexer!) is not as difficult to accomplish as it sounds. The PNP switches that were used in the original strobe system are now reconnected to the digit anodes and all of the like segment cathodes are connected in parallel (a to a, b to b, etc.) to the outputs of the 7447. This effectively connects one digit at a time to the 7447 driver.

In order to switch the BCD inputs from the 7475 latches, I will resort to a trick that will undoubtedly cause a few designers to cringe. It does not follow the teachings according to Texas Instruments, but it does work. Anyway, each BCD coded signal is applied to the inputs of a 7400 quad NAND and all the like outputs of the several 7400s are wired together. Data switching is accomplished by turning on the Vcc to the desired 7400. The complete multiplexed display system is shown in Fig. 3.

Unfortunately, this circuit will not work for all displays. The problem is that the out-

Fig. 3. Multiplexer for common anode LEDs. All transistors 2N3906 or equivalent. Note — inputs to F400 multiplex switches are inverted data.



put of the 7447 can only sink 20 mA per segment. This means that if you have 8 digits the average current per segment cannot exceed 2.5 mA. The resistors (sorry) in the segment lines serve this current limiting purpose. This would probably work fine for the smaller displays or possibly the newer high efficiency types (HP 5082-7650 – I don't know where to get them). For complete flexibility, the segment driver should be able to sink a maximum of 200 mA. That would allow ten digits at 20 mA per segment. The obvious way to do this is to add external transistors to the segment driver lines. An additional disadvantage to this is that this circuit will only drive common anode LED displays. Take a look at the ads in the back of this *73* and you will find that the inexpensive displays that were originally designed for calculators, clocks, and multiplexed operation are almost all common cathode types.

Since we are starting from scratch in this section, we might as well design the final display driver for common cathode displays. It should also be capable of driving up to 10 digits at 20 mA per segment (look at Fig. 4). One additional feature is a one shot (74122) tied to the blanking input of the 7447. This allows variable display intensity by changing the amount of time the digits are strobed on. Duty cycle of each digit can be varied from 10 per cent (full blast) to less than 1 per cent (almost off). If you don't want all this versatility, then leave out the 74122 and connect the blanking input to the 1 kHz clock as previously described. The rest of the circuit is just an expansion of the previous circuits. A 7490/7442 1 of 10 multiplex driver is used to strobe the display digit cathodes (through Q1, Q3, Q5, etc.) and at the same time turn on the required 7400 multiplex gate (through Q2, Q4, Q6, etc.). An important point is that the 7400 gate inputs are connected to the Q outputs of the 7475 where normally data is taken from the Q outputs. This is done because the 7400 inverts signals applied to its inputs. If no inversion can be tolerated, use a 7408 (same pinout but is an AND gate rather than a NAND gate) as the multiplex gate. It will work the same as the 7400 except that the data will not be inverted.

Because we are using common cathode digits, the outputs of the 7447 are polarity inverted by Qa, Qb, Qc, etc. Transistors Qa, Ab, etc., and Q1, Q3, etc., should all be capable of conducting 200 mA continuously (to be on the safe side). For the PNP types (Qa, Qb) a Sylvania ECG 159 or a Motorola HEP would work well. An ECG 123 or HEP S0002 are ideal transistors to use in the Q1, Q3, etc., slots. Q2, Q4, etc., can be any silicon PNP transistor. Actually, you could probably use any silicon transistors of the proper polarity you happen to have for any of the devices. Give them a try – if they get too hot to touch, try something else.

The End

There are a few more ways to light a display besides just connecting a 7 segment LED to the tail end of a 7447. While the other methods make things a bit more complex, some of those help control your electric bill and others can reduce your parts bill. So use one of these systems in your next (what the heck – rip that new counter apart) project. If anyone asks, you'll be in a position to bore them at length about the marvels of multiplexing. ■

Instant QSO Recall System

-- gaining peer respect

Notice the choice of the word "gain" rather than "earn" in the title of this piece. What I'm going to tell you about will dazzle and amaze your friends — and hams all over the world. The technique is easy to implement, costs very little, and satisfies a craving deep within some of us to continually be "one up" on everyone within earshot (or receiver-shot).

I've been a radio amateur for nearly 25 years, and I can tell you the name, QTH, and other interesting information about anyone I've ever QSOed — and I can find the information in about four seconds or less.

Now, I work with computers every day, and I've been interested in microprocessors ever since I saw the first MITS ad — but if you're thinking of a QSO file application, I can beat any affordable machine technique for under $15.00.

Before I tell you this deceptively simple procedure, let me examine with you *why* someone would want to do this. Why would you want to store away and retrieve quickly information about radio contacts?

The reason *I* do it is that I get a boot out of coming back to a call with the caller's name, like: "Hi, Brad. How are things in Omaha?" It blows his mind, usually, and we end up discussing the system (and my phenomenal "memory"). And, of course, after 20+ years of doing this I just can't stop!

Most of us who care about such things have tried QSO filing systems and abandoned them. If you filled out a 3 x 5 card on every contact, you would soon have too many cards to warehouse, much less use to enable finding any particular contact quickly. And using a whole card is a waste of space and material (in addition to being ecologically unwholeseome). So what's the system?

My system, and I don't claim originality, requires that you purchase 676 file cards. I use 4 x 6 cards; you might want 3 x 5 or even bigger ones. You'll also need a box in which to put them and some alphabetic dividers. I bought all three items in a stationery store (at today's prices the total bill is about $14.00). Try to get dividers with mylar-reinforced tabs, and index cards with lines on at least one side.

With a pen or pencil (here's your chance to be creative) write "AA" in the upper right (or left) corner of a card. Make the letters comfortably large, since they should last a lifetime and your eyesight will not always be as keen as it is today — 3/8 to ½ inch high should do nicely. In the same way, put "AB" on the second card, "AC" on the third, and so forth. By the time you're through, the last card will be lettered "ZZ" and your writing hand will be *very* tired. I actually had my wife do this lettering; it kept her busy for a couple of hours and she didn't spend a dime during that period — maybe I've got something here after all.

Take a break, solder all connections to this point, and relax. Admire your handiwork (or your wife's). Insert the dividers into the deck of cards in front of each group, so that there are 26 cards behind each divider. See how symmetrical it all is? Psychologists say that symmetry is gratifying.

There's your instant-access QSO file. It will hold more than 20,000 QSOs, and you'll be able to find any one of them in less than four seconds. *And*, it will never occupy more space than it does right now.

I put one QSO per line on each card as I work a new station. I record callsign, name, QTH, date, band and whether a QSL was sent/received (a checkmark for a QSL sent, a circle if one is received). There is additional room for other info if you wish, and, if there is a lot you want to write about a specific contact, you can put an asterisk on the line and write paragraphs on the back of the card.

Hold it! Which card does a QSO go on? I put the contact on the card that matches the *last two letters* of the callsign. I chose the *last* two instead of the first two, because this gives a more normal distribution; in many DX countries you will find callsigns grouped heavily toward the front of the alphabet. See how it works? As an example, my "KF" card has everyone on it that I've ever worked whose call *ends* in "KF": W7GKF, EA3RKF, WB6NKF, and so forth. I would be on *your* "KF" card.

That's all there is to it. When I hear a CQ (or call one), I can locate the right card as soon as I hear his callsign, determine if we've talked before, and come back with his name in practically no time. If it's a first contact, I fill out his line during the QSO. You've got room on a 4 x 6 card to put comments like: "photography," "cars," "DX," and so forth on the line, so that you can recall his special interests on your next QSO. If you are into Ten-X hunting, county hunting, DX chasing, or other subinterests, you can tell instantly whether this contact is a new one or not.

It's not much trouble to maintain (really!), and it's a great memory substitute.

Get yourself a box, 676 4 x 6 cards, and a set of alphabetic dividers, and snow your friends! ■

New PC Techniques Unveiled!

-- dig out your old chemicals

Regardless of how you go about it, etching printed circuit boards can be a chore unless you happen to be making them commercially on a continual basis. After all, when the artwork is complete for the first board, making additional boards is not all that difficult. The same is true for any other type of printing process – the first page is always the most expensive.

However, if you are like most hobbyists, you are not interested in making 50 to 100 identical PC boards. Usually, you are interested in building one circuit at a time. This leads us to the basic problem faced by all hobbyists today – it takes as much effort to make that one PC board for your favorite project as it does for a manufacturer to make fifty.

For this reason, printed circuit boards for the casual builder of electronic projects have become both a solution and a problem. They are a solution to reducing the time it takes to wire a circuit *after* the board is etched. They are a problem due to the time that it takes to etch the board in the first place. They are a solution to minimizing wiring errors – after the boards are etched. They are a problem in that an error in the artwork will be duplicated in all boards etched from the original artwork. In this case a small error in the beginning is multiplied by the number of boards etched.

In this article, we will review some advantages and disadvantages of PC boards, various techniques available today, a few application guidelines, and the recently introduced "Stamp It & Etch It" product. Let's begin with some disadvantages of PC board construction.

Disadvantages

Printed circuit boards (or the etching of them) can be a big bugaboo in any circuit builder's life. If you have etched boards before, you already know why this is so. In many instances, you may have discovered that it takes much longer to etch the board than it does to mount and solder components on it. While you were making that discovery you may also have concluded another characteristic of making circuit boards: Depending on the technique you use, it may take just as long to make one as it does to make 5 or 10. Why? Well, whether you are making 1 or 50, you must first prepare the preliminary layout, plan the location of components, make the final artwork, and, depending on the process used, prepare a negative or positive film.

Up until this point, the required time is the same regardless of the number of boards being made. The next steps involve exposing and developing the PC blanks, and finally etching the boards themselves. If you have the facilities, it may be possible to etch several boards in one tank. This mass production is the main advantage to using PC boards in the first place. For the average hobbyist, however, the advantage of mass production has little value, since many of our projects usually involve only one type of board at a time.

Also, if you are not fortunate enough to have a special place set aside to make PC boards, another disadvantage becomes obvious. Each time you want to make a board, it is necessary to set up equipment, being careful of chemical spills and then putting everything away when the project is completed.

This can sometimes be very annoying, to say the least. Especially when you accidentally change the color of your kitchen countertop with a little ferric chloride.

Some Advantages

But before I paint too bleak a picture of PC board techniques, what are some of their advantages? I've already mentioned that once they are etched, PC boards can save you much time in wiring a circuit – in addition to minimizing wiring errors. Also, once you have perfected a layout and worked the bugs out of a critical rf circuit, the results can be duplicated by anyone following the same layout.

For prototypes and one of a kind projects, PC boards can also be very useful. In most of these applications, the film process is usually bypassed by making the layout directly on the copper blank (using dry transfer, resist pen or tape). This technique can save much time in getting your circuit from the "paper" stage to a finished product.

In addition, new tech-

niques are continually being developed to make it easier for the hobbyist to build electronic devices. One new development is the "Stamp It & Etch It" technique, which will be evaluated later in the article. This kit is actually a set of rubber stamps consisting of TO-3 pads, 1C pads, component and edge connector fingers. But, I'm getting ahead of myself. More on this later.

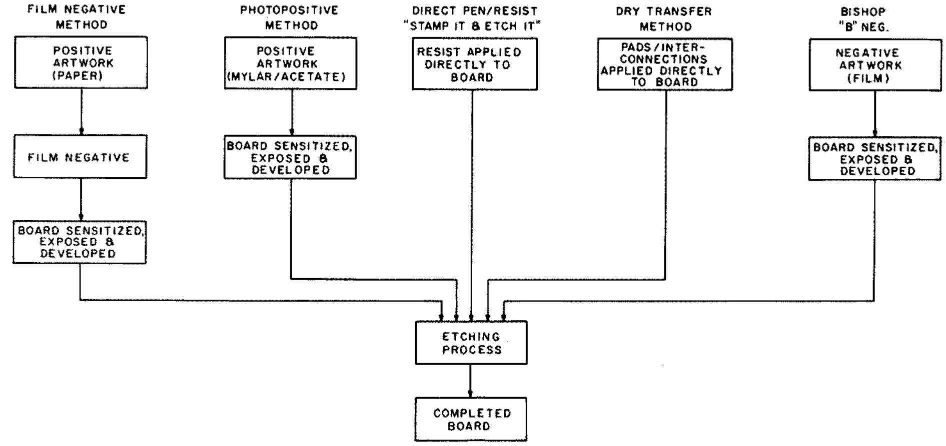

Fig. 1. Block diagram of the steps required for each method.

Present Practices

There are several ways to make PC boards today. To name a few of the present methods: direct pen resist/etch, dry transfer, film negative, photopositive, Stamp It & Etch It, and the patented Bishop Graphics method called the "B" Neg drafting system. See Fig. 1 for a diagram of these methods.

1. *Direct pen resist*. This is perhaps the most basic technique and, for simple circuits, is probably one of the easiest to apply. Once you have made a preliminary layout sketch of the PC pattern, you simply transfer it to a clean PC blank with a "resist pen." This is a felt-tipped type pen containing a heavy lacquer that is unaffected by the ferric chloride etching solution. When the copper board is placed in this solution, the copper is removed wherever it is not protected by the lacquer. In effect, the lines drawn by the pen are the actual circuit conductors on the completed board.

2. *Dry transfer method*. In this technique, pressure-sensitive pads and tapes representing terminals and connections are used. Once the layout has been drawn on paper, it can be transferred to the copper blank using carbon paper and retracing the lines. An alternate method is to draw the circuit in pencil directly on the copper board.

Next, the pattern is protected by applying dry transfer pads to the appropriate areas on the copper surface. These pads usually come in sheet form and are transferred to the copper surface by rubbing them off the sheet with an old ball-point pen that no longer writes. Then the conductor paths are made using tapes of various widths, depending on the circuit requirements. From this point on, the board is etched in the usual manner.

A variation to this method is to tape the board completely with wide masking tape. Then cut out the taped areas where you want to etch the copper away. The remaining masking tape will protect the copper from the etching solution. This method is particularly useful in rf circuits where large ground plane areas of copper are desired.

3. *Film negative method*. This is the standard in the electronic industry, since it provides extreme accuracy and high density of complex circuits. There are various types of drafting aids available for many applications. For example, there are tapes, tape shapes, donut pads, die cut multipad figures (for transistors, integrated circuits, etc.), connector strips, and many more. These pressure-sensitive drafting aids come in the standard sizes of 1:1, 2:1 and 4:1.

Here's how to use them. Start with a sheet of drafting paper with 0.1" grid lines. After you have drawn your layout to the scale desired, lay a sheet of Mylar™ or clear acetate over the pencil copy. With Mylar, I find it better to place the frosted side up – since you can easily write on this surface.

The next step is to transfer the pressure-sensitive pads to the correct places over your pencil layout. To remove small patterns from the backing, slip the blade of an X-acto™ knife under the pattern and lift it off. Then, using the knife blade as a holding tool, position the adhesive pattern over the artwork. If you happen to get the pattern positioned wrong, just slip the knife blade under it, lift it and re-position it. Once the patterns have been placed, a special black tape is used for interconnections.

We now come to the photographic step. If your layout is a 1:1 scale, you can make a contact negative using sheet film. This is recommended only for photography buffs who have their own darkroom. If you don't have a darkroom, the easiest thing to do is bring it to a photographer or a drafting/reproduction house and tell them what you want. The usual charge for making a negative is two to three dollars. If the scale of your artwork is other than 1:1, it will be necessary to have the negative reduced appropriately.

Once you have a negative of the circuit, it will be necessary to transfer the image to the copper blank. First, the copper is "sensitized" with a special chemical, usually in a spray can form. This is usually done in subdued light for photographic purposes. The coating must be uniform and dried for a period of time. Complete instructions for this process comes with the chemicals you buy, so we won't go into great detail here. The remainder of the process includes exposing the sensitized board with the mask over it, and developing the pattern. Then the board is etched in the usual manner.

Even in my abbreviated and once-over-lightly discussion of the steps involved, the whole process seems a bit complicated for most weekend projects. Then, when you consider the two to three hour process time, it seems there must be a better way. Many people I have talked to are turning more and more to local, commercial PC fabricators. But here again, cost may become prohibitive. Our local PC house charges around $5 or $6 for a 4" x 6" board. In many instances, the board costs as much as all the components that go on it. Is there an easier way?

4. *Bishop "B" Neg drafting system and the photopositive method*. Both of these methods have the advantages of eliminating the photo process of developing a film negative, but as a result they are suitable for 1:1 artwork only.

Basically, the Bishop "B" Neg method produces nega-

tive artwork which is used with a negative photoresist. By working with negative artwork directly, there is no need to have a film negative made – thus saving you time and money. Another advantage to this system is that it can be changed at any time without the expense of having a new film negative processed.

Additional information on this method can be obtained from: Bishop Graphics, Inc., 20450 Plummer Street, Chatsworth CA 91311.

An alternate method with similar results is the photopositive method. A positive resist has been developed that operates in reverse from the standard negative resist. Once your board has been sensitized with this positive photoresist, you can use positive artwork on Mylar or acetate film directly to expose the copper blank. In addition, no highly volatile hydrocarbon developers are needed as with the negative resist. Instead, only ordinary household diluted lye (sodium hydroxide) or caustic soda in water is used as a developer for the positive photoresist.

As with the Bishop "B" Neg system, changes may be made on the positive artwork without having to go to the expense of the photographic process.

Although there may be other suppliers of positive acting photoresist products, one company I am familiar with is Trumbull, 833 Balra Drive, El Cerrito CA 94530. They have a complete line of artwork aids, drill bits, and copperclad boards, and they spoil the hobbyist with prompt shipments.

5. *Stamp It & Etch It.* Always looking for new and easier techniques, I noted an ad one day for ACE Laboratories (now Rainbow Enterprises, PO Box 2366, Indianapolis IN 46206). What really caught my eye in the ad was the statement, "... reduces printed circuit board artwork from 2 hours to 10 minutes ..." This statement and the fact that the kit is offered on a satisfaction guaranteed basis was enough for me to send them $10.00 to find out what it was all about.

A few weeks later, I received my package and was anxious to open it up. This is what the kit contains:

(1) Individual rubber stamps consisting of PC board connector fingers, 16-pin dual in-line IC socket, 10-pin round, 8-pin round, TO-5, TO-18, large/small donut pad;
(2) Resist ink (small bottle);
(3) Ink pad;
(4) Resist pen (felt marker type);
(5) Etching containers (plastic bags).

Making a PC board with this method eliminates the preliminary artwork and photography. You merely stamp the component patterns directly on the PC board, use the lacquer pen to connect the components, and then etch the board. I used this basic method to etch a board containing 13 ICs, and the results were fairly good. However, as always, there are a few precautions that can be taken to insure that you obtain the results you are trying to achieve.

The usual preparations of the copperclad board should be made, such as a thorough cleaning to remove any dust, film or fingerprints. After the PC board is cleaned and dried, lay it aside and proceed to prepare the stamps. This is done by inking the pad sparingly with the lacquer supplied. Only about a 1" square area is required for most jobs. Trying to ink more than this will result in the pad drying out before you are finished with the board.

If you are using the stamps for the first time, ink them well and practice on a paper blotter. This is necessary in order for you to get the feel of the operation – and also to fill the pores in the rubber stamp material. When you feel confident in using the stamps, your next step is the PC board itself.

I found it difficult to place the stamp exactly where I wanted it on the board "free hand," without it sliding and smearing the ink. This problem was solved by using a small piece of wood (1" x 2", about 6" long) as a guide. Just hold the guide flat against the PC board with one hand, while you slide the rubber stamp against the guide until it rests flat against the copper surface.

Another variation to this technique can be used if you have several ICs in a straight row. Just temporarily clamp the guide and circuit board in a small vice along the line of the ICs. It's much easier to print each IC along the stationary guide, and you end up with all components in a relative straight line without too much effort.

The IC patterns seem to work out best. The first PC board I etched with this kit took more than the advertised ten minutes. However, the stamps do make it easier to etch a board.

They also have another feature which may have been overlooked. Before you begin to prepare a PC board for etching, it's usually necessary to prepare preliminary artwork. This is the process of determining component placement and interconnecting lines. I have found the rubber stamps invaluable for this phase of the process. In the preliminary circuit layout on paper, the stamps are used with an ordinary office-type ink pad. This is a great timesaver in producing professional-looking transistor and IC pin connections. This method is also much cheaper than using pressure-sensitive adhesive decals for the preliminary artwork. Bear in mind, however, that the stamps do have limitations and that the results depend to a great extent on how you use them. ■

How Do You Use ICs? - - part VII

Most of this series has been concerned with digital ICs. Just for a change of pace, here's one of the workhorse linear ICs – the LM380 series of audio power amplifiers.

There are two in the series: the LM380 (or LM380N), which is a two Watt power amplifier IC, and the LM380N-8 (or LM380CN), which is a 600 mW power amplifier in a minitype DIP (dual in-line package).

Besides the power difference, the pin connections are not the same, so we will take one at a time.

The first hurdle to get over is the power. It may not seem like much to talk about something which only puts out 600 mW or two Watts. This must be put into correct perspective.

Most amateur and communications type equipment usually has an audio power output in the neighborhood of one or two Watts. Even the much prized R390 or R390A only has a 600 mW output.

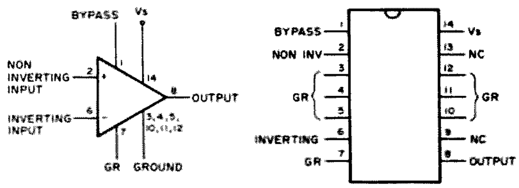

Fig. 1. LM380N 2 Watt audio amplifier IC.

If that doesn't convince you, just think how loud those teensy transistor radios sound. Most of them are only about 100 mW or so. Make no mistake. These audio ICs are well within the useful range of audio output power for most purposes.

Both ICs can actually put out more power than these basic ratings, but this gets into problems with heat sinking and other special precautions. This series is devoted to the easy and reliable.

Fig. 1[1] shows the pin configuration for the LM380(N) and the schematic symbol. This IC is in the 14 pin DIP configuration that has been commonly seen in this series.

Taken all by itself, the schematic representation of the device as a sideways triangle may seem a bit dumb. Once again we are faced with the problem that this is another computer symbol, the one for the amplifier function, which was retained for the device in other applications.

It is dumb, but it is what you are going to find on most of the schematics that use this and other IC amplifiers.

This means audio, i-f, rf, op and the works. They all use this same symbol, so watch the device number and the pin connections carefully.

This IC is another device with a minimum of external parts to go with it. There are a wide range of values that may be used depending upon the application though. Most are not critical, but you will have to understand how and why the choices were made.

Keep in mind that this device was intended for a number of purposes and has features that are not immediately applicable to the audio amplifiers you will be using.

It was designed to perform a number of audio jobs in intercoms, TVs, radios, tape recorders, etc., and for various control amplifier applications. Its use as a communications type audio amplifier is what we are interested in.

In order to simplify the circuit, it will be described in sections with the explanation of the associated parts.

Fig. 2 shows the IC and its usual output circuit. R1 and C1 are theoretically optional.

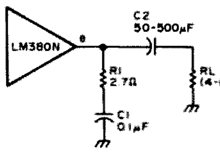

Fig. 2. LM380N output circuit.

They are there to prevent a 5 to 10 MHz oscillation which may occur with some types of operation.[2]

When bench testing the IC, they did help to prevent audio oscillation with some circuits. The values shown are the specific values to be used.

C2 is the output coupling capacitor. The low impedance output is capacitively coupled to the load. The voltage rating should be higher than the source voltage by a slight margin at the least.

The value is not critical for communications work. The typical range of values is from 50 uF to 500 uF. The basic effect is on the low frequency response. For hi-fi use you would want the larger value.

The LM380 will work with a load from four to 16 Ohms impedance. This gives you quite a bit to play with. There are plenty of speakers in this range and it will also work with your 8 Ohm ham headphones or a set of stereo phones.

The stereo phones can be hooked up as either a 16 Ohm load (series) or a four Ohm load (parallel). The advantage of using the phones as a four Ohm load would be that the shell of the plug could be grounded when the jack was chassis mounted. For 16 Ohm use, the jack would have to be insulated from the chassis.

There is slightly more output with the sixteen Ohm hookup, but not so much as to be critical. There will also be differences in the amount of actual audible output depending upon the efficiency of the speaker or headphones used. Still, the IC should be usable with almost anything standard you have on hand.

Fig. 3 shows the power, grounding, and bypass circuitry of the IC. Pin 14 is the Vcc source pin and pin seven is the nominal circuit ground. Notice that there are six other ground pins.

These are not because extra grounding was needed. Their specific purpose is to be part of the heat sinking mechanism. When used with a PC board, they draw heat off to the solid foil where it can be dissipated safely.

The IC is designed for use with a minimum voltage of 8 and a maximum of 22 volts; however, those tested would not work below ten volts source.

While not always shown, the Vs pin should be bypassed if the supply is more than a few inches away from the IC. It probably is a good idea to bypass it anyway. This is to prevent audio oscillation. The value is not critical, and for most audio uses, 0.1 to 10 uF is common.

The other bypass capacitor shown is also optional in some circuits. Its function is to bypass the supply to the internal small signal high gain sections of the IC where power supply hum or other noise can get in and be amplified.

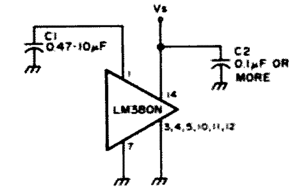
There is an internal split load resistor for these stages which is bypassed to ground when extra decoupling is desired.

For audio circuits, this is usually desirable. Here the common value is in the 5 to 10 uF class, but it is not too critical. This does have an effect on the frequency response, but for audio use, there did not seem to be any appreciable difference with or without in the test circuits.

It probably won't degrade performance for communications work either. Use the bypass to take advantage of the extra decoupling.

We now come to the matter of power output. At the beginning of this article, the LM380 was listed as a two Watt amplifier. This presupposes that it gets the required drive and the rated source voltage.

Fig. 3. LM380N power, bypassing, and ground circuit.



With its full 22 or so volts, it will have that much output, but not with less source voltage. Here what seems like a decided liability actually works for you.

Most transistorized or IC amateur and communications type equipment is also designed for mobile use, specifically with a design center of the 13.8 volts or so that the normal car or truck will have. Nominally this is specified as twelve volt operation. This can make design work easier for you.

Instead of a wide range of operating conditions, you can expect the 12 to 13.8 volt range to be your norm. These test circuits were tested from 12 to 14 volts for actual operating characteristics.

This automatically uses the first rule of IC and transistor work: Don't push the ratings. The 14 volts is well within the rated voltage for the device and is a very safe margin. The big question is: What does it do to the actual performance?

Mathematically, you get quite a bit less output with less source voltage. When tested, it worked out to about 500 mW at best. This may not sound like much on paper, but in terms of real sound it is more than you want.

This will take some explaining. The output voltage through the capacitor is the signal voltage that drives the speaker or headphones.

This voltage is derived from the source voltage. The IC automatically centers itself at one half the source voltage and the output voltage swing is the source voltage minus the voltage differential required for the device to operate, usually several volts.

This means that the output voltage will be less than the source voltage by several volts. That is all there will be. You can drive the input up to the point where this maximum signal output voltage is used up.

Overdriving will result in distortion caused by the signal being clipped when there is no further output voltage swing available.

Not to worry. Just keep it in perspective. You can't hear a number. How does the IC sound? The IC was tested using the output from an FM tuner as the signal source. This is a more demanding signal than speech, as music shows up distortion much quicker and the acceptable distortion level is less.

Using a good quality speaker, a number of types of signals were tried, everything from acid rock to classical music. Rough measurements of the output to the speaker showed approximately 500 mW available without distortion. Slightly more power was available before distortion became unacceptable.

However, listening in the room the speaker was in was somewhat uncomfortable. It was too loud. In fact, it could be heard through much of the rest of the house. The room door had to be shut to continue testing.

At these power levels, that safety factor becomes quite an advantage. After several hours of continuous use at the maximum usable level at fourteen volts, there was no evidence of any heat problem. There is a built-in thermal overload circuit, but

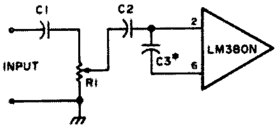


*Fig. 4. LM380N input circuit (*optional for tone).*

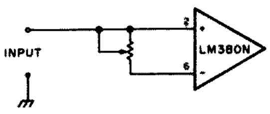

Fig. 5. Common mode volume control.

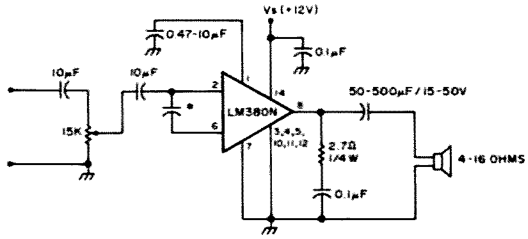

*Fig. 6. Full schematic, LM380N audio amplifier. *See text.*

the device did not even feel warm to the touch.

For enjoyable room listening, much less power was needed. 30-40 mW would fill the room. There was one slight problem at that power. The base response suffered. For communications work this would not even be noticed, but with music it was noticeable.

This may not be a fault with the IC or circuit though. None of the components were really chosen for hi-fi response. As the volume control was almost all the way down, the low resistance across the IC's input may have caused the loss. It is more likely that at the low power level there was simply too little drive to the speaker at low frequency.

This is a problem with any speaker. It takes more power to drive them well at low frequencies. This usually means poor response unless a base boost circuit is used. This would be uncommon and unnecessary for communications use.

The input circuitry of this IC is the hardest part to understand, but not to use if you know what you want.

There are two inputs, one inverting and one non-inverting. They do just what the name implies. For audio use the non-inverting input is commonly used. But what to do with the other? There are several options because the device was intended for many types of inputs.

The unused input can be left floating, grounded through a resistor or capacitor, or grounded directly. The application notes give the particulars for other uses; what we want are the standard receiver audio section type answers.

In this case, the usual procedure is to leave the inverting input floating or ground it directly. The audio input goes to the non-inverting input, pin two.

This is shown in Fig. 4. C1, C2, C3, and R1 are not critical, but do have an effect on the input, so a word of explanation is in order.

C1 and C2 are signal coupling capacitors. Their value is not critical. The voltage rating should be sufficient to block the dc voltage from the preceding stage from getting to the IC input.

The value affects the frequency response, the low frequencies in particular. For communications use, anything from 0.05 uF on up will do. For best low frequency response, a small electrolytic can be used. Values around 10 uF are common.

The high frequency response of the LM380 is quite good. In fact, the audio quality is rather brilliant. It is more high frequency response than is needed or usually wanted.

Most communications amplifiers are built to limit high frequencies, so there is usually the equivalent to C3 in most circuits. Even for music it sounds better to take out some of that brilliance and make a more natural sound.

The C3 value is not critical and is usually a matter of personal choice. A value of 0.005 to 0.05 uF would be the likely range.

In the schematic shown here, C3 is between pins 2 and 6. It can also go between pin 2 and ground. It made no appreciable difference if pin 6 was grounded or ungrounded. Grounding may be advisable in some circuits to avoid stray coupling to the input, particularly if the inverting input is used and the other is left unused.

Volume control R3 is not critical. The test circuit used a stray 15k Ohm volume control. It would seem likely that anything up to 1 meg would also work. A smaller value might also work, but at some point might make for less signal to the amplifier.

In this circuit, the volume control is capacitor coupled to the IC. It seemed to work as well when the tap went directly to pin 2 of the IC, but there may be some loading of the IC with a low resistance across it.

In a transistor circuit, trying to use a volume control the same way as in a tube grid circuit would upset the bias of the transistor and mess up the circuit, so the control is normally isolated from the input.

With ICs you often have the option of using a tube type volume control circuit, but the isolated volume control as shown is more common.

The IC is quite sensitive. It is rated at 0.5 V ac maximum input. It only took a tiny amount of the available input voltage for full undistorted output. Going beyond this will certainly cause extreme distortion and may damage the IC.

For your own test purposes, the output from an FM tuner makes a good wide range test signal. An audio oscillator is a good steady test signal. Remember to keep the level low. Start with the IC's volume control all the way down and raise it gently until you get a clear signal.

There is one trick type of control circuit peculiar to the IC which relies on its differential amplifier capability. This is the "common mode" control shown in Fig. 5.[3]

Here the two inputs are played off against each other and the circuit provides very little loading to the IC or the signal source.

This circuit is not common for communications use and is shown for example only. The normal audio hookup of the IC is what you want for most audio or communications purposes.

This basic complete circuit is shown in Fig. 6[2] with typical parts values. This will certainly handle any job you will be interested in doing at first.

Fig. 7[4] shows a similar circuit from an actual receiver schematic. This is only shown for example and not for duplication. One of the interesting things about it is that it would appear to be in error.

Before getting into the errors, look at the input circuit. It is quite similar to the test circuit shown. The inverting input is directly grounded. The 0.001 uF capacitor would appear to be for audio tone quality.

The volume control is similar to the test circuit. The exact significance of the 0.047 uF cap and 10k resistor combination was not explained in the text.

It may be partly for tone quality or perhaps some form of peak limiting to the IC. It may even perform some filtering action in the circuit.

The value of the output resistor is not given nor is the 0.01 uF capacitor explained. Perhaps again for audio response. In any case, that far the circuit is fairly straightforward.

The trouble comes with the rest of the schematic. Part of it suffers from assuming that the reader already knows the LM380 audio IC.

The pin with the asterisk (*) obviously refers to the ground pins 7, 3, 4, 5, 10, 11, and 12. The bypass capacitor obviously refers to the bypass pin. But this is only obvious if you are already familiar with the IC and know that pin 1 is bypassed.

The schematic is ambiguous. The nine could refer to either of the two pins near it. As it happens, pin

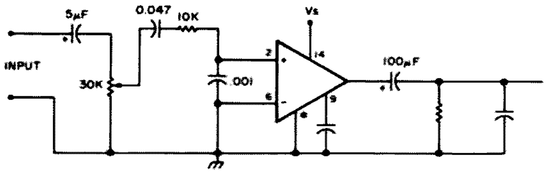

Fig. 7. Schematic from published article.

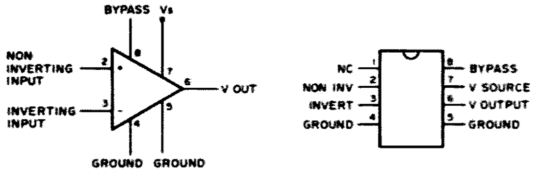

Fig. 8. Mini-DIP 600 mW LM380N-8 symbol and pinout.

nine of the LM380N is no contact, which is quite non-committal.

The bypass should have been labeled pin one and the output is pin eight. All told, this could have been a very frustrating project to duplicate.

This shows why it is so important to get the data sheet for an unfamiliar IC. The pinout diagram would have shown the error and the application notes would have given enough information to make corrections.

Most of the simple audio uses will follow a hookup very similar to our test circuit, which could probably be dropped right into any project using the LM380N as its audio amplifier stage.

The only time you might want to deviate from something similar is when the text clearly gives a reason for a different hookup. A given circuit might be more susceptible to rf pickup or the like and require extra circuitry.

We next come to the LM380CN, the mini-DIP LM380N. This is nothing more than an eight pin IC about half the length of the other. It will still fit into a standard IC socket.

The important thing to watch is that the pin connections are not the same as the other IC, and, of course, the power is not the same.

Other than that, the hookup is just about the same, at least as far as the external components. Fig. 8[1] shows the pinout and schematic symbol and Fig. 9 shows the whole amplifier schematic. It is virtually the same as the other.

Within the 12 volt design range it gives just about the same performance, perhaps slightly less output but not enough to matter.

There is one serious drawback though. To get the comparable output it means that the IC is working at almost full capacity. It runs slightly warm to the touch.

As a design decision, there would seem to be little in favor of using this IC. Unless you are really into teensy, it would be better to use the larger IC.

It will give better performance within that range and it will be running very conservatively. This translates into longer term reliability.

There is a wide price differential between sources for prime quality LM380s, but the usual difference between the 2 Watt and the 0.6 Watt is only about 35¢, hardly worth bothering about.

There are several ways to buy the LM380. You can buy prime quality or an experimenter's selection. This will give you a higher IC count but will contain defective units.

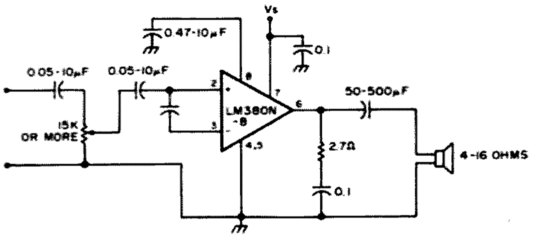

Fig. 9. LM380N-8 600 mW audio amplifier circuit.

For your first time out, get some prime quality. Two or three will do for a start. Then make up a test circuit using your supply and speaker. See how the prime quality units sound and perform. Then you can try the experimenter's bagful.

The selection I got contained several that were not even audio amplifiers, and there were only about 12 usable out of the original 50.

This was quite a bit less than advertised, but on a price per unit basis, quite a bit cheaper than buying prime quality. You will probably get about the same results, but without a working standard to compare with, you may have a hard time testing and knowing that you are right.

This brings up a word about how these things can act up. There are four basic categories of trouble and there may also be some slight shading in between.

1. The unit can be quietly uncommunicative. It just sits there in the circuit and no audio comes out. All other indications are normal.

2. There can be audio but it will be weak or distorted. This is where a knowledge of how the circuit is supposed to work pays off. It could be circuit trouble, too. At this point, you have to wiggle a few wires and make sure the IC is properly seated in the matrix or socket. All other indications are normal.

3. The IC draws too much current. This may or may not give good audio response — usually not or it hums. The IC should not draw more than about 25 mA when idling. Usually it does not go high with the 12 volt or so supply in use. Some ICs want to go a few hundred mA. This is decidedly unhealthy. Scrap them pronto.

4. The IC is suicidal. This IC usually doesn't work at all but draws over an Amp. While testing one, the power supply meter was doing a tarantella at 1.5 to 2 Amps. Not a sound out of the IC. As I reached for the supply lead, smoke began to curl up from the board. Exit one IC.

This brings up a practical testing matter. You don't want to watch your supply go up in smoke because of a defective IC. Make sure your supply is protected by fuses and common sense.

It would be a good idea if the whole physical layout is right within eyesight in front of you when the power is applied. Then if anything takes off you will be able to quickly cut off the power.

I use a clip lead on the ground lead of the power supply and touch it to the circuit ground to apply power at first. If nothing goes wild I clip it on and watch for any later effect. So far my supply has remained in one piece using this system.

This is probably more detail then actually needed for most applications. It really is a simple IC to use successfully. However, by now you should have all the information you need to apply it to any use you have and know how to make allowances in other circuits if you did not have the exact parts specified. ■

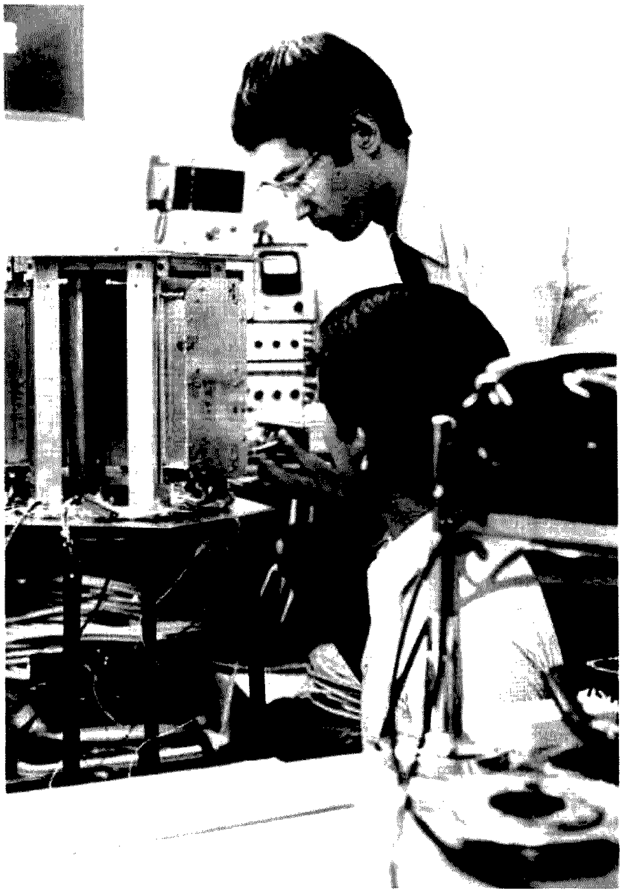
AMSAT

Amateur radio is about to undergo a fundamental change. About fifty years ago the discovery that the HF bands would support long distance communications revolutionized amateur radio. At that time amateurs were limited to working their friends across town or the occasional DX station using high power and long wire antennas on the long wave bands. With the introduction of the short wave bands, DX contacts became commonplace, with small antennas and relatively low power. Encouraged by this DX potential, amateurs explored the HF bands, using shorter and shorter waves to work the world. Time passed, technology improved, frequencies got higher, and wavelengths shorter, until a barrier was found at a wavelength of about ten meters. The ionosphere only allowed reasonably reliable DX contacts at frequencies below about 30 MHz. Thus, for years, DX contacts were in the main limited to HF. Now that barrier is being broken and a fundamental change in amateur radio is again about to take place.

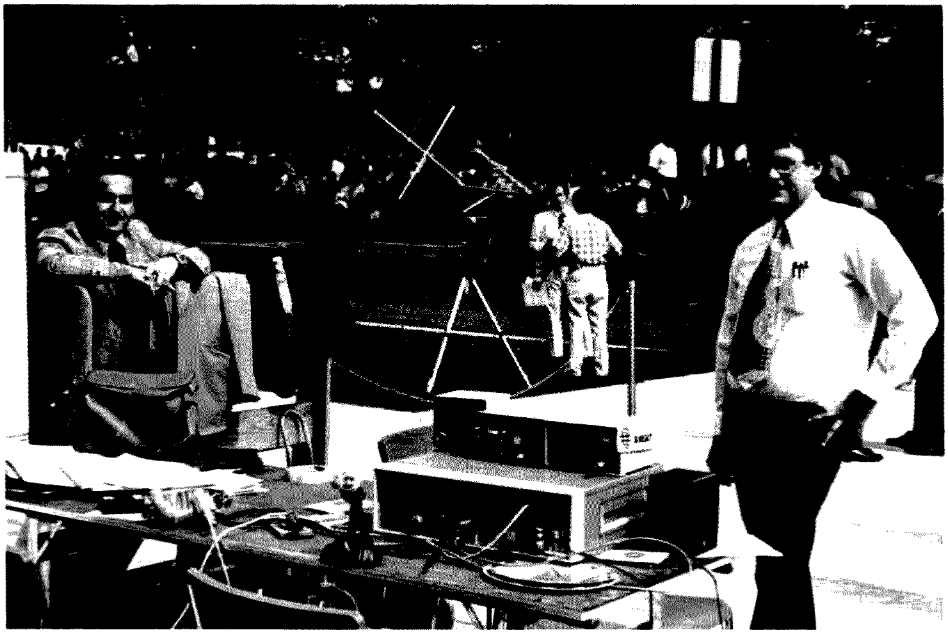
In the change that amateur radio is about to undergo, whole new bands will open up, with characteristics unlike any of those existing at present. When will that change take place? It will begin with the successful launch of the first AMSAT-Phase III spacecraft now scheduled for late in 1979.

AMSAT is a worldwide organization of radio amateurs with more than 3000 members in over 85 countries. However, everyone communicating via the AMSAT-OSCAR 6 and 7 spacecraft are not members of AMSAT, and there is no requirement that they become members. It is estimated that many thousands of radio amateurs have made use of the OSCAR spacecraft. If you count the amateurs who have been involved in commanding the spacecraft (so as to ensure that they are available for use when scheduled), and you count those amateurs involved in publicizing AMSAT (and making known the capabilities of the existing satellites and the potentials of the new ones), and you count the amateurs building those new ones, you will find that only a few hundred out of an estimated 50,000 radio amateurs worldwide are pioneering their way into the satellite era of amateur radio.

AMSAT is currently managing the day-to-day operations of the AMSAT-OSCAR 6 and 7 spacecraft. These satellites are in low altitude orbits and allow communications ranges of up to 5000 km or so without any skip zones. However, the band is open for only about 20 minutes at a time, five or six times a day, when the satellite passes within range. While satellite communications are indeed possible, they are somewhat more difficult than conventional communications using the HF bands. Also, relatively little commercial equipment is available to users at this time. The AMSAT-Phase III spacecraft will open the VHF bands for hours at a time. In use, these bands will appear to be similar to the HF bands, in that they will open up for communications with stations to the east of the user, slowly change to include areas to the north and south, and then open up to the west before closing down. There will, however, be a lot of overlap between these areas. Contacts will be possible with the whole of the northern hemisphere and much of the southern for hours at a time with no skip zones. No skip zones. Can you imagine what that will mean? Anyone in the northern hemisphere will be able to hear anyone else. Can you imagine a round table QSO between stations in New York, Washington, Los Angeles, Miami, Tokyo, Paris, Tel Aviv and Moscow — all able to hear each other at the same time? This is not possible using the HF bands. Nets, emergency traffic handling, educational demonstrations and plain CQ calls will all assume a new dimension.



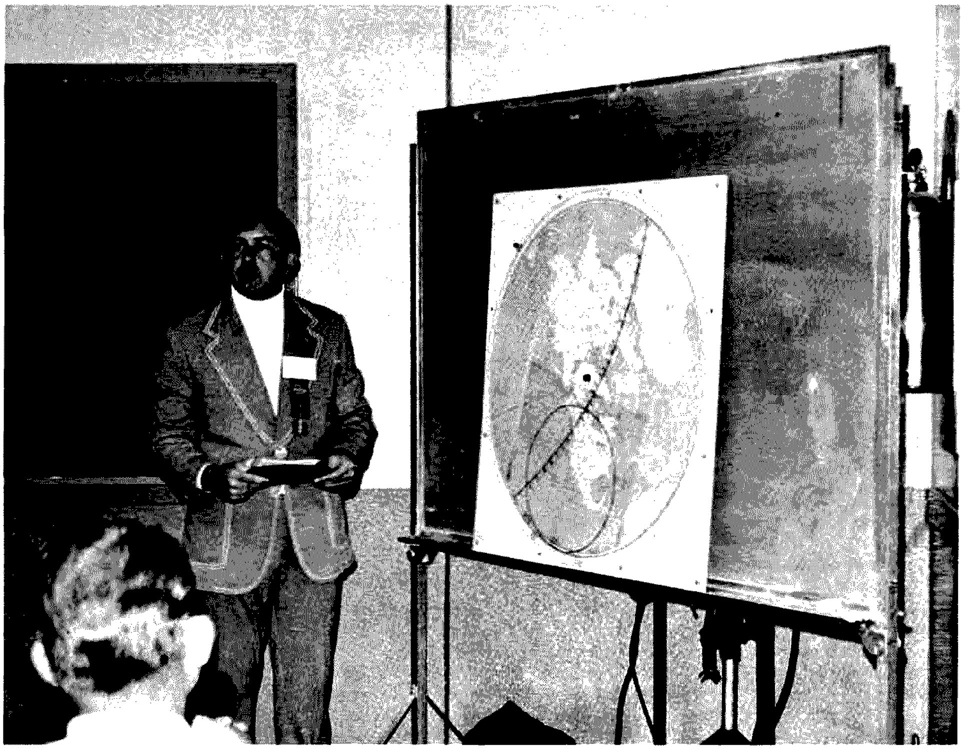
Japanese amateurs working on prototype of Mode J transponder for the AMSAT-OSCAR D spacecraft.



Tom Clark WA3LND standing next to a low cost portable OSCAR terminal on the mall in Washington DC at the opening of the National Aeronautics and Space Museum, July, 1976.

Historically, AMSAT has worked to build operational, simple to use satellites, and now our goal is within sight. Our space program has been international in the true cooperative spirit of amateur radio. Our first spacecraft was AUSTRALIS-OSCAR 5, built in Australia by radio hams at Melbourne University. It was not a communications satellite, but carried, among other things, a prototype command system which proved that radio amateurs could control the operation of satellites in outer space. AMSAT-OSCAR 6, built by Australian, German, and American hams, was the first long-life amateur radio communications satellite. Designed for a one year lifetime, it is only now showing signs of old age after four and a half years of faithful service. AMSAT-OSCAR 7, built by American, Australian, Canadian, and German hams, is now approaching its three year operational design lifetime.

In order to keep interest in space communications active through 1980 (when the first AMSAT-Phase III spacecraft is expected to become operational), AMSAT is stretching its



Dave Clingerman W6OAL, conducting a classroom demonstration.

to within a few miles of the exact location. NASA is now studying an operational satellite system to do just that, saving incalculable numbers of lives and thousands of dollars in search and rescue costs. Data collection techniques using remote sensors relaying data via satellite to a central location have been demonstrated. Mobile terminals have been set up in cars, boats and private aircraft. Medical emergency traffic has been simulated. Electrocardiograph data has been transmitted coast to coast, phone patches have linked Hawaii to the mainland US, and direct "broadcasting" experiments have taken place. Many of these activities are only being talked about by the professionals, or, if they are being done, are being done at many times the cost, in terms of both the spacecraft and ground equipment.

AMSAT-OSCARs 6 and 7 have paved the way. They have shown that we can use the satellite bands and have some grasp of the potential that they have to offer, but impressive as these are, much is yet to come. Contacts via AMSAT-OSCARs 6 and 7 require some technical expertise. The spacecraft must be tracked as they speed across the sky, since passes only last about 20 minutes and the range is limited. The AMSAT-Phase III spacecraft will change all that. Spacecraft OSOs will become very simple to implement. Communications will be possible for hours at a time, but these capabilities will not come for free.

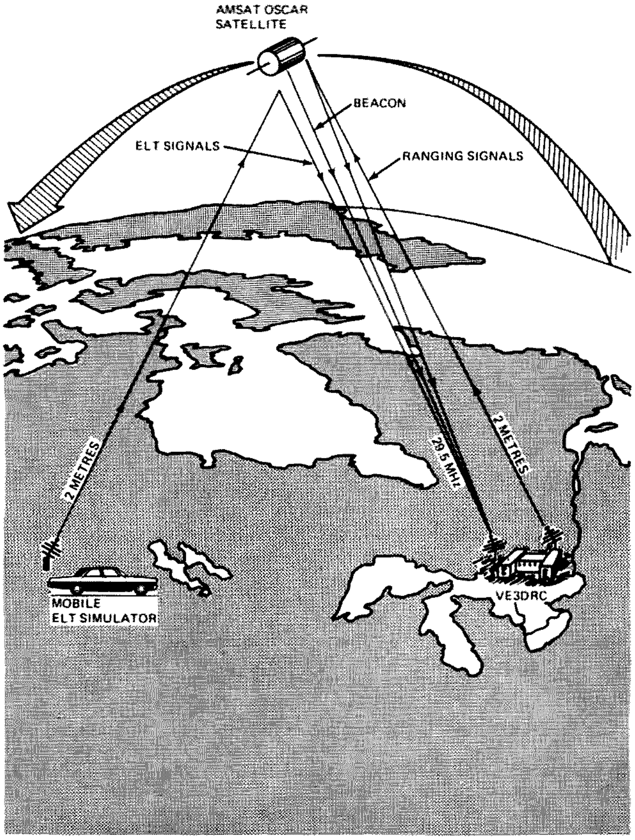
Hardware costs for the first

resources and building one more low orbit satellite (known as AMSAT-OSCAR D until launch). AMSAT-OSCAR D (or A-O-D) is a joint effort of the Japanese AMSAT Association, Project OSCAR, and the ARRL, all working closely in cooperation with AMSAT. AMSAT-OSCAR D is presently scheduled for launch in late 1977, and is primarily intended for continuing support of the educational program. Once the spacecraft is launched and in orbit, it will become AMSAT-OSCAR 8 and will be considered to be in the public domain, so that anyone can use it for communications purposes. The ARRL will then become responsible for all the operations management aspects of the satellite. To ensure operation consistent with the design of the spacecraft, AMSAT will act as technical consultants for the operations management of AMSAT-OSCAR 8 during its active lifetime. The ARRL will also pay AMSAT the sum of $50,000 to partially reimburse AMSAT for the development and construction costs of the spacecraft. Space satellites are not cheap. AMSAT-OSCAR 7 cost in the neighborhood of $60,000, but a similar commercial communications spacecraft could have cost $2,000,000.

AMSAT also has a policy of not obsoleting equipment. AMSAT-OSCAR 6 carried a 145.9/29.5 MHz transponder. AMSAT-OSCAR 7 introduced a UHF/VHF transponder on 432/145.9 MHz. This transponder, designated as MODE "B" (145.9/29.5 became MODE A), clearly demonstrates the superior capabilities of VHF for amateur satellite transponders. The mode B link on AMSAT-OSCAR 7 is clearly superior to the mode A links of AMSAT-OSCARs 6 and 7. AMSAT-OSCAR D will also carry a mode A transponder and a new mode J transponder (built in Japan) on 145.9/435.15 MHz. Similarly, the first of the AMSAT-Phase III spacecraft will carry two transponders, utilizing modes A and J. Thus, as amateurs become more interested in satellite communications and obtain equipment, they can be sure that their investment will not become obsolete with the passing of any one spacecraft.

The AMSAT-Phase III spacecraft will be accessible with full quieting SSB or CW signals by any amateur radio station using an output power of the order of 50 Watts, and small, rooftop, TV-style antennas. Thus, any apartment dweller with a balcony having some northern exposure will be able to work the world. In fact, the performance of this equipment communicating through an AMSAT-Phase III spacecraft will usually be superior to a kW-quad combination on the HF bands.

Amateur spacecraft have long passed the days when launches were made available because the spacecraft were there, or to demonstrate that hams could do it too. There are now many spacecraft competing for launch opportunities. AMSAT thus has to show how the piggyback launch can be implemented for a minimum of cost to the launching agency, and also show cause as to why a spacecraft should even be carried aloft in the first place. Thus the OSCAR series spacecraft have also been used for scientific and public service demonstrations of communications capabilities. There have been educational transmissions to introduce the space sciences to students in classrooms, and demonstrations of an emergency crashed aircraft locating technique in Canada and the USA, which has shown that it is possible to pinpoint the position of a simulated crash site



Conception of the emergency locator experiment used for locating crash sites. The computer interface was located at VE3DRC. Tests showed that the crash could be pinpointed to within a few miles of the actual site.

AMSAT-Phase III spacecraft are estimated at $200,000 (a government or commercial spacecraft providing similar performance would cost millions).

How can you help? First of all you can become a member of AMSAT. Dues are only $10 per year. If you are already a member (and even if you are not), you can become a life member for a donation of at least S100. You will then receive the *AMSAT Newsletter*, a quarterly publication devoted to amateur satellite communications. It contains details about existing, future and planned spacecraft. It contains operating news and acts as a forum for communicators. You can also encourage your local radio club to become a member society at $20 per year ($200 life).

You can also help the AMSAT-Phase III program financially by sponsoring part of the satellite. You can sponsor any number of solar cells ($10 each), battery cells ($200 each), solar panels (S2,000 each), transponders ($5,000 each), an onboard microcomputer ($8,000), or a rocket motor ($10,000). All donations including the $100 life membership donations are tax deductible under section 170 of the IRS Code. All sponsors will receive a certificate suitable for framing acknowledging their contribution. A plaque honoring for posterity contributors of $1,000 or more will be carried on the spacecraft in orbit around the Earth, and contributors will receive a replica of the plaque as a momento.

If you are willing to contribute time or money and would like to get involved in bringing a new era to amateur radio, join AMSAT's team. For further information about all aspects of AMSAT and the ongoing amateur radio satellite communications program, write to me, Joe Kasser G3ZCZ/W3, c/o AMSAT, Box 27, Washington DC 20044.

CHICAGO FM CLUB HOSTS OSCAR NET

The Chicago FM Club has begun holding a weekly OSCAR net on its two meter 16/76 repeater. The net, hosted by Ralph Wallio K9JPR, disseminates late information gathered from low band OSCAR nets meeting earlier in the evening, and rebroadcasts them at 9:00 pm Chicago time on Tuesdays. Ralph also gives the OSCAR 6 and 7 orbit times for the Chicago area for the coming week, and answers questions concerning the satellites' operations.

CONTESTS

Editor:
Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

IARS/CHC/FHC/HTH QSO PARTY

Starts: 2300 GMT Friday, June 3
Ends: 0000 GMT Monday, June 6

An SASE to K6BX will bring detailed information. Contest is open to all amateurs and SWLs worldwide. Same station may be worked on each band and mode; SSB and AM are different modes.

EXCHANGE:

QSO number, RS(T), name, CHC/FHC number, US state and county or similar division. Nonmembers send HTH instead of CHC/FHC number.

SCORING:

CHCers – score 1 point per QSO with other CHCers, 2 points per QSO with HTHers; 1 additional point if YL, B/P, FHC, Novice, CHC-200, Merit or Club station, or if on VHF/UHF; double above points if QSO is outside own country. HTHers – contacts with other HTHers count 1 point, with CHCers count 3 points. Rest same as above. SWLs – use above depending on whether CHC member or not.

MULTIPLIERS:

Each different continent, country, ITU zone, and US state counted only once.

FINAL SCORE:

Multiplier times total QSO points is final score. Multi-operator stations divide score by number of operators.

FREQUENCIES (for US and DX as allowed):

CW – 3575, 3710, 7070, 7125, 14075, 21075, 21090, 21140, 28090, 28125. Phone – 3770, 3775, 3790, 3943, 3960, 7070, 7090, 7210, 7260, 7275, 14320, 14340, 21360, 21440, 28620.

AWARDS:

Hundreds of certificates and trophies in all categories and divisions are awarded. An SASE will bring further information from K6BX. Send all requests and logs to: International Amateur Radio Society, K6BX, PO Box 385, Bonita CA 92002. Logs should be mailed within 15 days after the close of the QSO Party.

CALENDAR

June 3-6	IARS/CHC/FHC/HTH QSO Party
June 4-5	Minnesota State QSO Party
June 4-5	SOWP QSO Party
June 11-13	ARRL VHF QSO Party
June 18-20	West Virginia QSO Party
June 25-26	ARRL Field Day
July 2-3	QRP – Summer – Contest
July 4	ARRL Straight Key Night
July 9-10	IARU Radiosport Championship
July 16-17	Apollo II 8th Anniversary Contest
July 16-17	10-10 Net Summer QSO Party
Aug 20-21	New Jersey QSO Party
Aug 20-21	Worldwide SARTG RTTY Contest
Sept 10-11	Washington State QSO Party
Sept 10-11	ARRL VHF QSO Party
Sept 24-25	Delta QSO Party
Oct 1	Open CD Party – CW
Oct 15-16	Open CD Party – Phone
Oct 15-17	Manitoba QSO Party
Nov 5-6	ARRL Sweepstakes – CW
Nov 12-13	IPA Contest
Nov 13	OK DX Contest
Nov 19-20	ARRL Sweepstakes – Phone
Nov 19-20	WWDXA Internation CW Contestst
Dec 3-4	ARRL 160 Meter Contest
Dec 10-11	ARRL 10 Meter Contest

MINNESOTA QSO PARTY

Starts: 1800 June 4
Ends: 2359 GMT June 5

Sponsored by the Heartland Amateur Radio Club, Staples High School. No restrictions as to mode or operating time, all bands 80-10 mtrs. Only one transmitter allowed in operation at one time; no crossband contacts. Novices compete against Novices, Techs against Techs. Net QSOs are not valid. Please do not interfere with nets or traffic sessions.

EXCHANGE:

RS(T), county (MN only), ARRL section or country (others).

FREQUENCIES (+/- 5 kHz):

Phone: 3910, 7235, 14280, 21365, 28525. CW: 3525, 7035, 14035, 21035, 28035. Novice/Tech: 3725, 7125, 21125, 28125.

SCORING:

One point per QSO, 2 points if on CW, 5 points if Novice or Tech. (Note: Novices and Techs must identify their license class each QSO, such as WBØXXX/N, or /T.) WBØTTZ, the HARC station, counts 10 points per QSO per band. MN stations multiply number of ARRL sections plus DX countries (W/VE excluded) times QSO points. Others multiply QSO points by number of MN counties (max. 87). Phone and CW are one contest – please score as such.

ENTRIES/AWARDS:

Details and log sheets available after May 10 upon receipt of an SASE. Stations making 50 or more QSOs must include a check sheet for each band and mode used. Logs must include date/time in GMT, band, mode, and exchanges. Certificates to state winners as well as high Novice and Tech scorers in USA and DX stations. MN stations must have 10 QSOs from a county for county awards. SASE required for return of awards and summary. Usual disqualification criteria. Logs must be postmarked by July 2nd. Send logs to: HARC, c/o Steven J. Gardner WBØMAO, PO Box 261, Staples MN 56479.

SOWP QSO PARTY

Starts: 0000 GMT June 4
Ends: 2400 GMT June 5

The Society of Wireless Pioneers, SOWP, will hold their 2nd annual CW QSO Party with a certificate issued to all participating members who contact 10 or more fellow members during the event.

FREQUENCIES:

55 kHz up from low end of each band. Novices should try the middle of each band.

EXCHANGES:

SOWP identification numbers as minimum, other optional.

ENTRIES/CERTIFICATES:

Members desiring a certificate are required to submit a listing of contacts made with call, member's number, and time of contact. All entries should be mailed to: Pete Fernandez W4SM, VP for Awards, 129 Hialeah Road, Greenville SC 29607. Include an SASE and mail no later than June 20th.

ARRL VHF QSO PARTY

Starts: 1900 GMT Saturday, June 11
Ends: 0600 GMT Monday, June 13

Check the May issue of QST for any last minute changes!

Entrants may operate no more than 28 of the 35 hours during the contest period. The seven hours off-time must be taken in increments of 30 minutes or more. Listening time counts as operating time. All contacts must be made on amateur bands above 50 MHz using authorized modes. Fixed, portable, or mobile operation under one call, from one location only, is permitted. Any transmitter used to contact a station may not be later

used to contact another station during the contest period with any other callsign. Contacts made by retransmitting either or both stations (such as repeaters) do not count for contest purposes. Each contact exchange must be acknowledged by both operators before either may claim contact points. A one-way confirmed contact does not count.

EXCHANGE:

Exchange simply ARRL section.

SCORING:

On 50 or 144 MHz count 1 point per contact; on 220 or 420 MHz count 2 points per contact; on higher UHF bands count 3 points per contact. Final score is then the total QSO points multiplied by the number of different bands for additional credits, but crossband contacts are not allowed. Also, aircraft mobile stations cannot be counted for section multipliers.

ENTRIES:

All logs must be postmarked no later than July 7th and sent to: ARRL, 225 Main Street, Newington CT 06111. Logs and entry forms are available through this same address; please include an SASE. Usual awards will be issued and the standard disqualification rules will apply.

WEST VIRGINIA QSO PARTY

Starts: 2300 GMT Saturday, June 18
Ends 2300 GMT Monday, June 20

All amateurs are invited to participate in the QSO Party sponsored by the West Virginia State Amateur Radio Council. There are no operating time limits during the contest period. The same station may be worked on different bands for additional points, but only once per band regardless of mode. West Virginia stations may work each other.

FREQUENCIES:

35 kHz up from the bottom edge of each CW band and 10 kHz inside the general portion of each phone band.

EXCHANGE:

QSO number; RS(T); and county (if WVA), state or country.

SCORING:

A power multiplier will be allowed as follows: 200 Watts or less dc input = 1.5; over 200 Watts dc input = 1.0. Out-of-state stations determine their score by multiplying the number of QSOs times the number of different West Virginia counties worked (55 max.). This total is then multiplied by the power multiplier as defined above for the total score. West Virginia stations multiply the total number of QSOs by the sum of the different WVA counties, US states, and ARRL countries worked. This result is then multiplied by the power multiplier to determine the final score.

AWARDS:

To be eligible for an award, a station may have only one unassisted operator. Awards will be issued to the highest scoring WVA station, 1st runner up in WVA, 2nd runner up in state and the highest scoring station in each state and country. Decisions of the Contest Committee of the West Virginia State Amateur Radio Council will be final.

LOGS/ENTRIES:

Logs must indicate date, time, QSO number, callsign, QSO number received, signal reports, and county, state or country of the station worked. Indicate the mode and band also. Logs should be sent to: West Virginia QSO Party, PO Box 299, Dunbar, West Virginia 25064. Logs should be received no later than July 16th, and no logs will be returned.

ARRL FIELD DAY

Starts: 1800 GMT Saturday, June 25
Ends: 2100 GMT Sunday, Juna 26

Rules are generally lengthy (2 pages in *QST*); please refer to the May issue of *QST* for detailed information and for any changes since last year's rules. Briefly, the general rules are as follows:

The contest is open to all amateurs within the ARRL sections; foreign stations may be contacted for credit but are not eligible to compete. Each entry will be classified by type of operation: Class A — club group set up specifically for Field Day operation operating portable without commercial power; Class B — non-club stations set up portable without commercial power; Class C — mobile stations; Class D — fixed stations using commercial power; Class E — fixed stations using emergency power for transmitters and receivers.

All entries will further be classified by the number of transmitters utilized. Class A and B stations not beginning to set up before 1800 GMT on Saturday may operate the entire contest period. All others may not operate more than 24 hours total. Each station may be worked once on each band; voice and CW are considered different bands (all voice contacts are equivalent and RTTY = CW).

Class A, B, and C stations may contact anyone, but classes D and E must contact only Class A, B, or C.

EXCHANGE:

RS(T) and ARRL section or country.

SCORING:

Phone contacts count 1 point each and CW contacts count 2 points each. Final score is sum of QSO points times multiplier for highest power used at any time during the contest period, plus bonus points. Power multipliers: Multiply by 5 if 10 Watts or less dc input power and non-commercial main power source or motor driven generator; multiply by 2 if less than 200 Watts; multiply by 1 if over 200 Watts up to 1 kW; multiply by Ø if over 1 kW (note — dc power on SSB is half PEP power). Bonuses: (only for Class A or B stations) 100 points for 100% emergency power; 100 points for "natural" powered contact (only one QSO req'd); 50 points for public relations; 50 points for message origination for SCM or SEC; 5 points for each message received and relayed during FD period up to a maximum of 50 points; 50 points for completing at least one QSO on CW via OSCAR.

ENTRIES:

Standard disqualification rules apply. All entries should be sent to: ARRL, 225 Main Street, Newington CT 06111. Official log and entry forms are available from the same address for an SASE.

SARTG ACTIVITY TEST

1815 to 1930 GMT, last Wednesday of each month during 1977

FREQUENCY:

3.6 MHz (RTTY).

EXCHANGE:

RST and QSO number from 001 each month.

POINTS:

Bulletin station counts 2 pts., all other contacts with Scandinavian stations count 2 points.

ENTRIES/AWARDS:

Logs should be sent not later than 8 days after test to: Einar M. Thomassen LA1LN, Radyrvegen 30, N 3900 Porsgrunn, Norway. Results will be published in the monthly *SARTG Bulletin* and the year's result will be calculated according to the best 9 of 12 possible rounds. Diplomas will be given to the 5 best stations! Note: The bulletin station is currently LA3S, but may be changing callsign!

WORKED SCANDINAVIAN AMATEUR TELETYPERS

Offered by the SARTG for 2 Watt RTTY contacts with the following number of Scandinavian stations: Scandinavian stations — 25 (general), 50 (bronze ribbon), 75 (silver ribbon), 100 (gold ribbon); European stations — 16 (g.), 35 (b.r.), 50 (s.r.), 75 (g.r.); other countries — 8 (g.), 15 (b.r.), 25 (s.r.), 50 (g.r.).

All bands may be used. QSL cards for general class and bronze and silver ribbons are not necessary — just list calls, dates, and times of contacts. For gold ribbon it is essential to have contacts with the following prefixes: LA, SM, OH, TF, OX, OY, OZ. Reference to SARTG contest logs or photocopies of 7 QSL cards is sufficient. Fees are 10 IRCs for general class and 6 for ribbons. Applications should be addressed to: Carl Jensen OZ2CJ, Meisnersgade 5, Randers, Denmark.

VERMONT CENTURY CLUB AWARD

In celebration of VT's bicentennial, the Burlington ARC has reinstated the VT Century Club Award that was first issued in 1966. The award is available to any amateur for confirmed 2-way contacts with VT stations. Contacts may be on any HF band on any mode. The award will be issued for an indefinite period, with all contacts made during 1977 and later applying for the award. The basic award certificate will be issued for working 10 different VT stations. Seals for working 25, 50, 75, and 100 additional stations (10 initial contacts count as part of first 25 total). Applicants should submit list of calls in alphabetical order, showing city, date, band, and mode for each worked. Those sending in lists for higher class endorsements should indicate which seal is desired. QSLs must be in your possession, but should not be submitted. Instead, a written certification of the above list by another amateur will be accepted as satisfactory proof. The award chairman reserves the right to inspect any or all of the QSLs. The fee is $2.00 for US stations or equivalent for DX. Make check or money order payable to the Burlington Amateur Radio Club, Inc. No fees for higher class seals, but an SASE must be included. Send all applications or inquiries to: The Burlington ARC, VTCC Award Manager, PO Box 312, Burlington VT 05402.

Uncle Sam's Surplus List

- - and how to get on it

Each month, the United States Government auctions off tons of surplus supplies and equipment through its Defense Property Disposal Service. DPDS is Uncle Sam's abbreviation. Examples of the types of materials involved include: scrap metals, fire control equipment, aircraft and aircraft components, naval ships, railway equipment, motor vehicles and components, wood and metal working equipment, refrigeration and air conditioning equipment, heating and plumbing equipment, tools, electrical and electronic equipment (1. communications, 2. electrical parts, 3. computers and peripherals, 4. lighting and alarm systems), medical and laboratory equipment, photographic equipment, home and office furniture and supplies, appliances, AND SO MUCH MORE!!

Much of the merchandise offered for bid is declared surplus because of a lack of need for it on the government's part rather than because it is worn out. Most of it is in fair or better condition and has usually been well maintained. These auctions are open to all and most of them are conducted by mail. Bids are usually a penny or two on a dollar's original value. Auctions are held for every United States Military Installation in the world, so there is sure to be one or more near you.

Getting on the Bidders Mailing List

In order to be placed on the Official Bidders Mailing List, it is necessary to apply to the Defense Property Disposal Service. The DPDS address and a suggested form will be found at the end of this article. Upon receipt of your request, the DPDS will send out an official application blank plus booklets explaining how to buy, what classes of materials are generally available, and what the rules are. You choose the type(s) of equipment you are interested in and the locations you are willing to pick up from if your bids are successful. The merchandise is broken down into classes and the areas are usually states.

When this application blank is returned to DPDS, your name will be placed on the Official Bidders Mailing List, and each time that some material that you want is available at locations that you have chosen, you will receive a bid catalog. Depending on the number of classes that you are listed for, it is possible to get quite a few catalogs each month.

Here's how it works: Say you are interested in aircraft components and electrical and electronic equipment in California. Each time that a catalog is issued that includes either of these two categories and some of which is in California, you will receive a copy. It may also include material you are not looking for or locations outside of California, but that is OK. You bid on what you want, when it is located where you want it!

Let's Look at the Catalog

These usually cover a broad category: aircraft or automotive or electronics, for example, and a group of contiguous states. All material is always available for inspection before bidding; therefore, the first item in the catalog is a list of the military installations involved and the names and telephone numbers of persons to contact for information and inspection. It is not necessary that you inspect before bidding, but it is recommended, especially on large bids.

Next, the equipment to be auctioned off is listed and described. Its specific location on the military installation is given and how it is packaged. Its condition is stated as poor, fair, good, or excellent, and whether it is used or unused. Its total weight and original cost are given. Some items are sold by lot, some by weight, and some per each. You bid accordingly.

After all of the merchandise to be auctioned has been listed, general bidding information is covered, as well as information on loading. Generally the government will load heavy bulky items, but not always.

Some bids require a 20% deposit, and when this is the case, it will be clearly stated. Of course, if yours is not the high bid, your deposit will be returned. It is entirely possible that only part of your bid will be successful if you bid on more than one item.

Each catalog has a bid opening date and time and all bids must be received before that date and time to be considered. If you are notified that your bid has been accepted, you will be expected to pay the remainder owed and remove your merchandise within a period of time stated in the catalog.

Remaining on the Bidders List

It is necessary to bid at least once every five catalogs in a given class to remain automatically on the Official Bidders Mailing List. However, you can continue your

name on the list by simply requesting that it remain there. Here's how that works: The DPDS will indicate on a catalog mailing label that they are about to drop your name from the bidders list for lack of activity. Included in each catalog is a renewal form that you fill in and mail back to DPDS. You're now good for another five months. You can continue this way indefinitely, but bidding is more fun. It's easier than it sounds.

Items purchased can be for your own personal use or for resale. For instance: 200 VHF radios bought at $2 each and sold at $20 each would make a nice profit. Most items are sold in quantity and the price per each is low, regardless of the original cost or present value. This could make for a pleasant and beneficial part time business.

That's it! It's easy! It could be profitable! Good luck! ■

CITY STATE ZIP CODE

Social Events

SCARBOROUGH, ONTARIO
JUNE 3-5

The Scarborough Amateur Radio Club invites you to the ARRL 1977 National Convention held on June 3-5, 1977 at the Sheraton Centre Hotel. There will be special programs for ladies and children, exhibition of world's leading ham equipment, contests, awards, Q.C.W.A. luncheon, royal order of the Wouff Hong, microprocessor forums, outstanding speakers and forums, and a CLARA luncheon. Saturday nite there will be a memorable dinner and dance. For further details write: '77 ARRL National Convention, P.O. Box 1011, Station "C", Scarborough, Ontario M1H 2Z4.

WENATCHEE WA
JUNE 4-5

The Apple City Amateur Radio Club of Wenatchee, Washington will sponsor the 6th Annual Central Washington Hamfest on Saturday and Sunday, June 4 and 5, 1977, at the park at Rocky Reach Dam, located 7 miles north of Wenatchee. Commercial exhibits, swap and shop tables, free trailer and tent space with electrical hookups. Banquet Saturday evening at 6 pm at the Columbia Hotel. Park will be open 2 pm Friday. Hamfest registration $3, XYL-YLs $1, banquet $3.75. Talk-in 146.07/67 WR7ADX, 146.760, 3.960. For more information write or call Apple City Amateur Radio Club, 919 N. Woodward Dr., Wenatchee WA 98801, (509) 662-8466.

ROME NY
JUNE 5

The 25th Annual Rome Ham Family Day will be held June 5, 1977 at the Beeches, Rt. 26, Rome, New York. There will be interesting programs for everyone including the XYL and children. There will be a giant flea market and 5000 square feet of air conditioned indoor display area featuring equipment displays, contests, xcvr checks, door prizes, speakers, etc. For more info write PO Box 721, Rome NY 13440.

CLEVELAND OH
JUNE 10-12

Computerest '77 will be held Friday, June 10, 4 pm to 10 pm; Saturday, June 11, 9 am to 7 pm; and Sunday, June 12, 10 am to 3 pm at the Bond Court Hotel, 777 St. Clair Avenue, Cleveland, Ohio. $2.00 per ticket. Your one ticket admits you to everything, including manufacturer's exhibits, MACC Club displays, flea market, seminars and tech sessions, and of course, prizes, games, demonstrations and good times. For more info send an SASE to Midwest Affiliation of Computer Clubs, PO Box 83, Brecksville OH 44141.

HERNANDO MS
JUNE 11-12

The Chickasaw Amateur Radio Association, Inc., "CARA," of Hernando, Mississippi presents its annual Tri-State Hamfest June 11-12, 1977 at the National Guard Armory in Hernando, Mississippi, 20 miles south of Memphis, TN on Interstate 55. Plenty of parking area with camping sites. Tables available at $2.00. Doors open 12:00 to 6:00 Saturday, June 11th, and 8:00 to 4:00 Sunday, June 12th. Prizes, food, and beverages. Talk-in on 146.31/91, 146.52, and 3987.5. For further information write CARA, PO Box 2, ATTN: R. Gates, Hernando MS 38632.

JEFFERSON CITY MO
JUNE 12

The Missouri Single Sideband Net Annual Picnic will be held June 12, 1977 beginning at 9 am in the Shelter House, Memorial Park, Jefferson City MO. Covered dish dinner, beverages furnished, lots of prizes. Donation $1.00 at the door. Talk-in 94/94. For more information contact WBØFND, Rt. 4, Box 886, Warrensburg MO 64093.

AKRON OH
JUNE 12

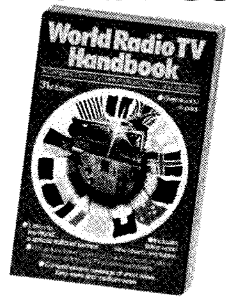
The Goodyear Amateur Radio Club of Akron, Ohio will hold its 10th Annual Hamfest and Family Picnic on June 12, 1977 at Wingfoot Lake Park between the hours of 10 am and 6 pm. The park is located southeast of Akron on County Road 87 near Route 43. Ample parking, rain shelters, picnic facilities, kids' play areas and refreshment stands. The flea market/swap shop space is free with the admission ticket. Gear displays, prizes, etc. Sorry — no overnight parking or swimming. Mobile check-in on 04/64. Family donation $2 advance, $2.50 at gate. For more info contact Don Rogers WA8SXJ, 161 S. Hawkins Ave., Akron, Ohio 44313. Phone: (216) 864-3665.

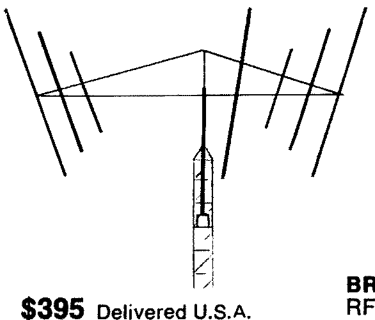
NEWBERRY MI
JUNE 12

The Tahquamenon Amateur Radio Society swap and shop will be held Sunday, June 12, 10 am to 6 pm at the Pentland Township Hall, 3 miles south of Newberry and 2 miles west on highway M-28. Refreshments at the site, ample parking, campsites available at a nominal fee. Reg. $2 at the door. Drawings and door prize. Many free family passes for tours in the famous Tahquamenon area. Many other prizes. Talk-in on 25-85, 28-88 52 & 94 simplex. Correspondence W8GBR.

ATLANTA GA
JUNE 18-19

The 49th Annual Atlanta HamFestival and 1977 Georgia ARRL





Convention will be held June 18 and 19, 1977 in Atlanta at the Downtown Marriott Hotel (rooms: $18 single, $24 double). This year's show includes 120 commercial booths, a 250+ car covered flea market and swapshop, more than 50 technical forums, and $6,000 worth of prizes. Advance registration is $3 individual and $5 family; at the door, $4 individual and $5 family. A preregistration package will be mailed on May 1st to all who have attended the HamFestival within the past three years; if you have not received a package by May 10th, you may write to Atlanta HamFestival, 53 Old Stone Mill Road, Marietta GA 30067 or call (404) 971-HAMS anytime day or night. Doors open at 9 am Saturday and Sunday.

CHAMBERLAIN SD
JUNE 18-19

The Medicine Butte Radio Association and Rosebud Amateur Radio Club will sponsor the South Dakota Ham-vention this year in Chamberlain SD on June 18-19.

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

WHEN THE JAMMER HITS

One of these days, unless the laws of chance have been repealed, your repeater is going to be the target of a persistent kerchunker or even a dedicated jammer, complete with a four letter vocabulary which would be *more fitting to the current run of* movies than to amateur radio. Outside of panic, what should you do?

The first thing, obviously, is to make some tapes and get together with the FCC. Horsepucky. Leave the FCC alone — they are not anxious to hear from you and would prefer not to be bothered. No, the first thing to do is give a big yawn and try to get some sleep. If, after a few days, the chap shows better than average stamina and keeps on messing things up, despite every effort of the repeater users to totally ignore him, then it's time to swing vigorously into phase two . . . a little longer nap, possibly with a dash of television viewing to break the monotony.

Okay. I can see you are determined to let this bugger get under your skin and you want action and you want it right now. Well, sigh, how about making up a couple of direction-finding loops and learning how to use them? Yes, I know the FCC can do this, but they are busy. Do it yourself and learn something. Two fellows with direction-finders can get a good idea of where the miseries are originating, and you can close in. Once you've located the jerk, you have to figure what to do about him. No, you can't do that.

Look on the bright side . . . fox hunting is a lot of fun and the exercise will be excellent for the club. The fact is *that your club should be ready for* this and have some practice before the fan gets hit. Get some transmitter hunts organized so the equipment will be ready to use and a few of the fellows will know how to use it.

The FCC has some direction-finding (DF) equipment which will give the bearing of a transmitter within a second. Now that amateurs have discovered microcomputers, perhaps it is time that we developed some of the same hardware. You can bet that the pages of *73* are open to any good DF articles and will make it worthwhile for fellows who dream up some good DF techniques.

One technique, which I've mentioned before, but of which little has been written, is one which examines the leading or trailing edge of a transmitter's carrier and puts it on a scope. My understanding is that every transmitter is a little bit different . . . that each rig has its own kerchunkprint. This means that when *someone tries to transmit without his* call, you can check out his kerchunkprint and compare that with some later time when he is just using the repeater to talk and gives his call.

Let's get busy with fox hunting circuits and apply some digital techniques to them which will make instant DF possible. And let's not forget to write it up!

NEW ORLEANS HAMFEST/COMPUTERFEST

The 1976 show came off so well that the New Orleans group has gotten bigger digs for this year. It's going to be at the Hilton Inn in Kenner this year, right across from the New Orleans International Airport. The dates are September 24-25th. Info can be had by writing box 10111, Jefferson LA 70181. Unfortunately, this is *the same weekend as a hamfest in* Hartford, so I'll have to miss New Orleans . . . perhaps the dates will not coincide next year . . . New Orleans is quite an attraction and I hate to miss it.

MAKE A MILLION

Forgive my enthusiasm, but every now and then a brilliant idea comes along and gets me all excited. Perhaps someone reading this magazine is looking around for an idea for a product which will sell like crazy, which wouldn't be very expensive to make, and which just about everyone needs. I have such a product in mind. It's so simple I don't know why it isn't available.

The chances are good that you are a coffee drinker . . . or at least tea? You may just drink it at dinner, but you are probably more like the rest of us in that you have several cups through the day. Most businessmen have coffee every now and then to keep the wheels churning. And how many of you don't have a mug on the operating desk with an inch of cold coffee in it?

Cold coffee . . . that's what did it to me. I was deep in a contact with a friend in Spain and I absentmindedly picked up my cup and took a swig of cold coffee. Iced coffee is something else . . . I can drink that, but cold coffee is an abomination and I came to my senses with a shock as the vile stuff hit my taste buds.

Someone is going to design a simple mug with a heater and thermostat built in to keep coffee warm. It can sit in a holder with the power transformer built in, making contact when you put the cup down . . . something like the rechargeable soldering irons, only without batteries. The electrical contact shoes can be built into the *bottom of the mug and the mating* spring contact in the holder. Will you

The New Orleans Hamfest/Computerfest.

Briefs

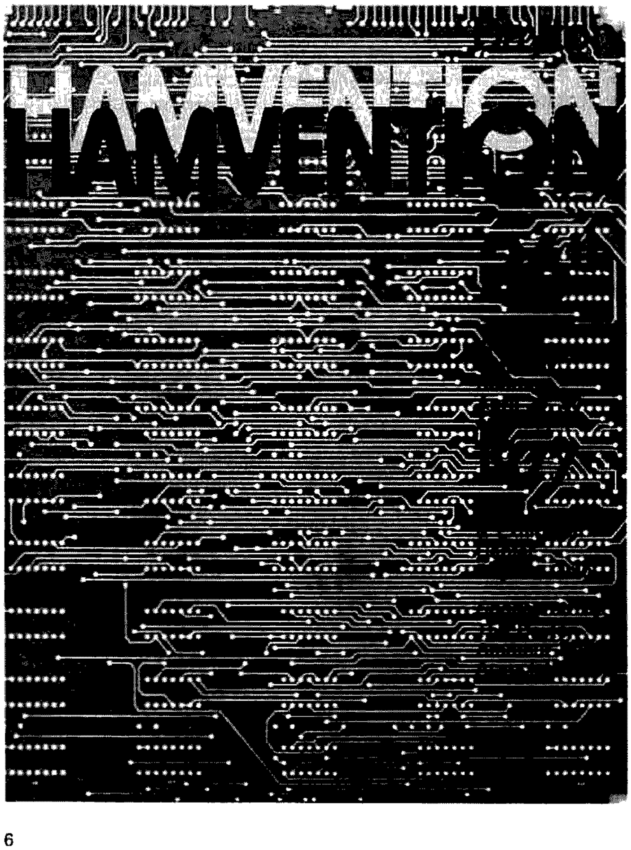
Compiled by Warren Elly WA1GUD

Got a good ham radio news story? Drop us a line, or call it in, and take home the 73 publication of your choice, provided we publish your news tip. Be sure to specify which book you want. OK?

It seems that "confidential document" Jack Anderson referred to in his national attack on ham radio (see *73* for June) came from the Electronics Industries Association (EIA). Southwest ARRL director John Griggs had quite a bit to say both about the EIA and Anderson during a talk at the Poinsettia ARC in California.

Anderson himself backed down a bit in his column published during the week of April 25th, claiming he never intended to attack hams. "We merely pointed out," Anderson wrote, "that the airwaves belong to the public, that there are far more citizens using CBs than ham equipment and that some of the federal regulators were hams." Anderson extensively quoted Senator Barry Goldwater K7UGA in the follow-up column, reprinted here from the *Washington Post.* "Goldwater complained that the CB enthusiasts often operate without a license and amplify their transmitters beyond the 5 Watt limit. They have also abused the system, he charged, in complete objection to all concepts of decency and gentlemanliness on the air. While this doesn't apply across the board, there are enough offenders that, I don't care how many frequencies they have, they are slowly going to destroy their own function. Many of these CBers never use their callsigns or their names. There are many who use profanity and what they discuss should never be carried on any airwaves. In many cities, prostitutes use these frequencies to solicit business, and I could go on and on." Concluded the senator, "I think I can safely say, Jack, that the amateurs throughout the years have contributed more to the art of communications than all of the so-called experts in the field. Our frequencies have been diminishing, not increasing. We have great pride in our craft."

Shortly after the second Anderson column appeared, an ARRL official told *73* that the Anderson situation was "under control." He went on to say that the author of the original story was now taking a Novice license course and was greatly interested in ham radio. We were unable to confirm that through a call to Anderson's Washington office, but we did learn that the original column had already been added to the EIA's battery of handouts promoting additional frequencies for CB. Official ARRL reaction to the Anderson mess came in two steps during late April. First, a directive to all League officials to "stand by" while headquarters found out how the column was written in the first place. Then, two weeks later, word came that the League has taken a strong step to offset the bad PR . . . a new award for any amateur whose response to the Anderson column was published or publicized. It's called the "Amateur Radio Promotion" award and is available only to League members.



Dayton's official attendance figure came in at 16,290, according to Dayton Amateur Radio Club officials. Well over 1,500 attended the Saturday night banquet, which featured NBC correspondent Roy Neal K6DUE, and a Special Event Achievement Award to the Pack Rat's Colombian EME DXpedition as HK1TL. At the AMSAT seminar, W8DX won a Special Communications Recognition Certificate for his long service to the OSCAR program. At the ARRL forum, President Harry Dannals W2HD raised a few eyebrows with news that the League may send a representative to Washington (this on the heels of similar discussions at a meeting of ARMA, the manufacturer's association). The League is apparently changing its long controversial stand that General Counsel Robert Booth, based in Washington, was all the representation that the ARRL needed in the capital. ARMA meanwhile voted to put the question of a Washington lobbyist to a committee, with a report upcoming at a future meeting.

A federal grand jury has indicted the head of the FCC's Gettysburg Special Licensing Division on bribery charges. According to a US Attorney connected with the case, Richard C. Zeigler's indictment was the result of an FBI investigation conducted in several US cities over a three month period. Zeigler is accused in the indictment of accepting four separate $100 bribes from amateurs seeking 1 x 2 (two letter) callsigns. US Attorney David Queen refused to name the amateurs, or comment beyond the indictment, but it was learned that Zeigler pleaded not guilty at his arraignment and posted $5000 bail. If convicted, Zeigler could receive 15 years in prison and $25,000 in fines *for each of the four* alleged violations. Zeigler's trial was expected to get underway in early June. Zeigler himself could not be reached for comment, and officials in the FCC's Personal Radio Division in Washington refused comment.

The Japanese government subsidizes the Japanese electronics industry — that was the ruling of a US Customs Court in mid-April, and it may have far-reaching implications for amateur gear (not to mention automobiles, TV sets, and hi-fi equipment). By court order the US government was told to raise import duties on Japanese imports, but, with billions of dollars at stake (not to mention the balance of payments situation), the appeals from Japanese interests are expected to tie up the case for years, if not kill it outright. An American TV manufacturer brought the court case, but business observers are not exactly "bullish" on its implications — since Japan (and other countries likely to be affected) are certain to retaliate with higher duty on American products, should the court order withstand the appeals.

No sign of the licensing boom slowing down . . . Gettysburg reports another record month in March, with the amateur population passing the 300,000 mark for the first time ever! Amateurs, then, have increased their numbers by over 35,000 in the last 12 months. Indications are that the growth will continue, with 350,000 licensees expected on the FCC computer by 1978.

CW comprehension exams should be in effect everywhere by the time this issue of *73* reaches you. The long delay in start-up was blamed on contract problems with contractors paid to produce the tapes and duplicates for each field office. FCC officials say test runs of the exams in

By Saturday afternoon the Hara was adrift in a sea of cars. For miles in every direction latecomers parked along the highways. Those lucky enough to make it through the 3-hour traffic jam gladly paid their parking fees.

the Washington DC office showed an 80 percent pass rate, compared to less than 50 percent for the old exams. Several who had taken the comp exams told us in Dayton that the new tests were actually harder . . . but FCC spokesmen countered that it was probably just their reaction to a new way of doing things.

The Illinois Attorney General's probe into the activities of Irael Treger (Trigger Electronics) has taken another turn . . . at deadline Treger was being held on $25,000 bond in the Cook County Jail. According to Deputy AG John McPhee, evidence was presented to the judge in Treger's consumer fraud case that Treger was planning to leave Illinois. On a writ of no exeat, Treger was arrested by local police. He was ill at the time of his arrest, and was taken first to Cook County Hospital. Treger, unable to post the bond, was then transferred to the County Jail Hospital. McPhee continues to process the fraud complaints against Treger, which reportedly amount to between $15,000 and $20,000. Trigger Electronics has been closed for some weeks now, after the landlord evicted Treger for failure to pay his rent. The eviction followed a court injunction barring Trigger from mailing catalogs or advertising, after the IL AG's office presented evidence that alleged the company was taking orders without inventory, and refusing to make refunds.

The president of H. F. International, John Randall, has refused to testify in an FCC hearing called to revoke his CB license. According to an FCC spokesperson, Randall was one of 21 HFers ordered to show cause why their CB licenses should not be revoked due to their involvement in HF International, an organization of pseudohams operating between 11 and 10 meters with amateur equipment, high power, and big antennas. Known as "Jack HF 61," Randall was charged with various violations of the FCC rules and Communications Act of 1934. The FCC alleged he had assigned call letters to CB operators for use instead of their FCC callsigns, that he had allegedly formulated rules instructing the unlicensed pseudohams to operate illegally on frequencies assigned to the Industrial and Business Radio services. The FCC notice also contended that Randall had published and sold lists which contained HF numbers, first names, and states of the pseudohams, thus avoiding FCC identification of their CB calls or locations. Randall refused to answer any of the FCC's questions, taking the 5th amendment instead. "Applicant therefore respectfully asserts his privilege against self-incrimination and his privilege not to give evidence against himself as set forth in the Constitution of the US and in particular the 5th Amendment thereto." Hearing Judge Walter C. Miller allowed Randall his right to remain silent, but added that a determination would come whether Randall had abused the Commission's rules by refusing to answer. In other words, Judge Miller would get his answers when the case reached the hearing stage. But before that could happen, Randall withdrew his application for renewal of his CB license. FCC officials say they have searched the files for an amateur license, and are sure Randall doesn't hold one. In all, 21 HFers were ordered to show cause why their licenses should not be revoked. Several will be going to hearing before this issue gets to you, and at least one of them has been refused a ham ticket by the FCC. That case came in Alabama, when a former CBer (whose license had been revoked for numerous violations) applied for an amateur license but failed to appear for a hearing called to air the FCC's objections to giving him one. As one FCC staffer put it, "Every now and then we get lucky, but for every one we catch there seem to be a hundred more."

The fourth notice on WARC has been released by now, although its significance to amateurs is limited. Number five is the big one, and we expect to have details in our next issue. FCC spokesmen say it will be released around the first of June, and it will be a critical point for amateurs, since it could be the last allocations chart produced by the FCC prior to the 1979 WARC conference. Notice number four relates largely to technical matters, such as how to designate a given emission and so on. The two inch thick fifth notice was due before the Commission just as this issue was going to press.

The antenna/zoning case of Hank Greenberg W2LTP (May *73*) has become snarled in the kind of local politics New Jersey is famous for. Greenberg attorney Elson Kendal W2INL has moved for dismissal of the case, charging Cranford area officials with destroying records and intimidating witnesses subpoenaed by the defense. Kendal says the tension surrounding the case proved too much for Greenberg, who was hospitalized in late April with a heart condition. His release (and a final session of the Union County Court hearing Greenberg's appeal) was expected at deadline . . . but Kendal fully expects a further appeal, possibly in the form of a jury trial. Greenberg, in the midst of the zoning dispute over erection of four telephone pole antenna supports, attracted national publicity for his role in the rescue of a ship sinking in the Caribbean with nine persons aboard. As for the fund drive organized in Hank's behalf, several hundred dollars have been collected thus far. Sid Lieberman WA2FXB, the organizer of the drive, says the fund is currently $4500 in the hole, with New Jersey amateurs the major factor missing! Lieberman told *73* that had surprised him, since he felt hams closest to the case would be the most willing to help out. As for the ARRL, Lieberman says the League has flatly refused to cooperate in the Greenberg case, other than to offer minimal advice. The address for contributions is The Amateur Radio Legal Defense Fund for the Benefit of Hank Greenberg W2LTP (ARLDF/W2LTP), Midlantic National Bank/Raritan Valley, PO Box 996, Edison NJ 08817, Attention Mr. S.J. Lieberman WA2FXB.

Although a Federal court decision is preventing it from collecting license fees, the FCC continues to spend

money. There is no solution to the fee problem in sight, but the need for more funding hasn't faded. In 1977, the FCC budget came in at over $55 million, but FCC officials have now requested an additional $1.6 million. A Washington spokesman told *73* the prime problem is the CB crunch – not only in new license applications, but in the cost of field operations teams tracking down illegal CB operators. There is also the cost of lab work, which has increased dramatically with the 40 channel changeover and adaption of new performance specifications. Congressional sources, though, are not so anxious to accept the FCC's judgment on the budget. As one House Appropriations Committee source put it, "The bureaucracy has to stop someplace . . . and it is not only the FCC that has some trimming to do . . ." The 1978 FCC budget request totaled nearly $60 million, but that may not be enough – a supplemental request is already in the works according to committee sources.

Much has been said and written about Texas, and the extraordinary lengths to which Texans will go to be "biggest." But the testimony of The American Radio Council, in support of Texas House Bill #1440, offers a view rarely seen of the RFI/TVI situation. Before the House Committee on Business and Industry, the ARC argued that all TV sets ought to be filtered to reject unwanted signals. (That's the thrust of bill #1440.)

"Consider, if you will, the

The Dayton flea market at its peak on Saturday . . . fleas as far as the eye can see.

The Sea-Q-DX Convention, set for July 29-31, is being held in Seattle. It is a combined affair, with the Northwest Division ARRL, QCWA National, Northwest Computer Club, and AF MARS Region 5 conferences all rolled into one event. 73 publisher Wayne Green will be featured speaker at the QCWA Luncheon.

following facts: (1) By FCC estimates, there are now 23,000,000 CB radios in use in the US. In 1958, there were basically none. (2) The State of Texas has over 1,500,000 CB radios in use today, using the FCC 'rule of thumb' of 2.5 CB radios per licensed CBer. (3) There are over 800,000 licensed CBers in the State of Texas, which leads the country in CB radio saturation. Texas has 50% more Citizens Band radio stations than the next largest state (California). Yet Texas has only 50% of the population of California. (4) Nationwide, the FCC received 40,000 RFI complaints from consumers in 1974. Of these 40,000 complaints, 36,000 of them would never have come to the FCC's attention if the manufacturers had corrected design deficiencies in their home entertainment products at the time of manufacture. They expect 200,000 such complaints this year!"

The ARC's testimony went on to say interference has reached crisis proportions in Texas. As for the alternatives to requiring built-in filters, a former FCC engineer-in-charge was quoted as saying, "To require a radio operator stay off the air under such circumstances is similar to requiring a motorist to stay off the highway because another motorist with no brakes is using it!"

The Amateur Radio Manufacturer's Association (ARMA) held a meeting at Dayton to discuss the new FCC radiation limits and pending dockets on linear amplifiers and type acceptance. But the thrust of the session was Docket 20777 and the effect of the new harmonic limits on the ham radio business.

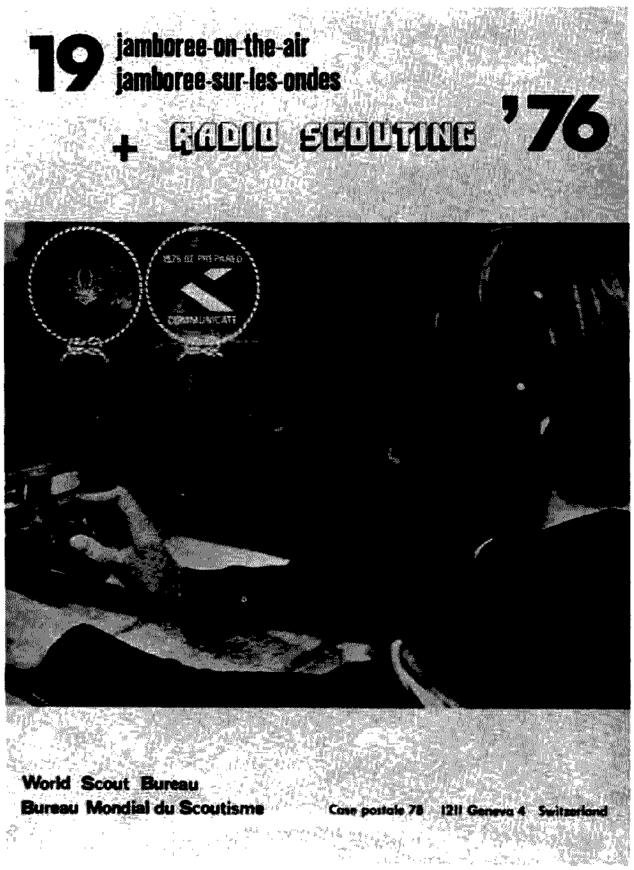
ARMA's hope is to grandfather existing gear, and the gear already on the production line or waiting for sale on dealers' shelves. January 1, 1978, is the retail cutoff date requested by ARMA, with an April 15, 1977, cutoff for manufacturing purposes.

As portrayed at the ARMA meeting in Dayton, the 20777 specifications came as a result of two distinct but related pressures. The first is the ITU international radio regulations, the basis of the upcoming 1979 WARC frequency allocations conference. It was felt in Washington, said ARMA's Bob Levine, that we must enforce the ITU limits here at home in order to have any right to limit the importation of amps considered illegal by American regulations. That's the second pressure point . . . information from various government agencies that huge shipments of broadband amps manufactured in Mexico, Korea, and Taiwan were headed for US markets. The new harmonic and spurious limits, then, were aimed at blocking further importation of "black box" amplifiers. Until now, the ARMA members were told, most bogus "black box" amps were manufactured here in the US, and it was the threat of thousands more coming in from abroad that forced the FCC's hand. Where all this leaves the American manufacturer of legal amateur radio equipment remains to be seen.

At deadline, the FCC had not acted on ARMA's grandfather clause proposal. ARMA itself was suffering growing pains, taking on new members and forming committees to deal with both pending and yet to be announced FCC proposals. Type acceptance is the prime fear, with most manufacturers convinced it will only raise prices and end up hurting the consumer.

The feeling is that anything – even 20777 – is better than type acceptance. The question is whether ARMA, or anyone in the industry, can find a better answer to the FCC's dilemma with the out-of-band pseudo-hams, the so-called HFers. And time, at this writing, is running out.

What can you do about supporting Senator Goldwater's RFI bill now before the Congress? Write your senator in support of the legislation which now has reached the Senate Commerce, Science and Transportation Committee. Of special interest are the members of the committee, whose home constituents carry some weight. The members include: Warren Magnuson (WA), the chairman, Howard Cannon (NV), Russell Long (LA), Ernest Hollings (SC), Daniel Inouye (HI), Adlai Stevenson (IL), Wendell Ford (KY), James Pearson (KS), Robert Griffin (MI), Ted Stevens (AK), John Durkin (NH), Edward Zorinsky (NE), Donald Riegle (MI), John Melcher (MT), Barry Goldwater (AZ), Bob Packwood (OR), Harrison Schmitt (NM), and John Danforth (MO). If you live in any of those states you are in a good position to urge an early hearing on the bill and have some positive effect on its progress through Congress. At deadline no hearing had yet been scheduled.



Twenty-five years ago in Norway, a man named Les Mitchell decided to add a dimension to scouting. Amateur radio was the natural choice due to its accessibility by scout troops around the world. An annual international event grew out of Mitchell's efforts, known as the Jamboree on the Air. And the 1976 version set new records for participation, with over 12,000 stations on the air representing nearly every country that embraces scouting. Here in the US, the BSA (Boy Scouts of America) fielded over a thousand stations, ranging from complex multi-operator setups at BSA headquarters in New Jersey, to deep woods portable operations in the Pacific Northwest. The idea is to demonstrate ham radio, while at the same time promoting scout friendship among the millions of scouts around the world. As one organizer put it after overseeing the operation of AC1NRG at Meriden, Connecticut, "The scouts traded information about their projects, made contacts to trade patches, but one thing seemed to always arise – they wanted to know who the other guy on the radio thought would win the World Series." Condensed from the *Report of the Nineteenth Jamboree On The Air*, World Scout Bureau, Geneva, Switzerland.

The debate over business use of repeaters continues . . . this latest word comes right from the FCC, via *The Hilltopper*, bulletin of the Tompkins County ARC, Lansing NY. (Anyone who disagrees with this should contact FCC Rules and Legal Branch chief John Johnson in Washington DC, since these are his interpretations.)

In considering the legality of a transmission, you first have to consider if there is a third party involved in any manner (i.e., someone besides the two amateur operators who are talking to each other). If no third party is involved, and providing an amateur is not regularly engaged in buying or selling radio equipment for a living, two amateur operators may consummate a sale of a piece of radio equipment without violation of regulations. However, Mr. Johnson "recommends" that actual prices not be discussed.

An amateur not regularly engaged in buying and selling radio equipment may also inform other amateurs during a net that he has a certain piece of equipment for sale or trade, but again, it is "recommended" that exact price not be discussed. Now, this is all changed if the two amateurs are handling this traffic to or for any person except themselves.

No third party traffic may be handled if either operator or any other person derives monetary gain from the transaction. One amateur asks another amateur to call or contact a hamburger stand ordering burgers, fries, etc. . . . Mr. Johnson replied that although the call seems innocent enough, a third party (the hamburger stand) has a monetary consideration and the call is interpreted as not permitted. Calls to commercial establishments are permitted providing that the purpose of the call involves, at least in part, the welfare of a person or persons. A nonroutine call to a commercial establishment such as to a motel while traveling in another city to find a room is permitted.

In other words, if you are sort of desperate, such as needing a part for a stalled car out on the highway, or a wrecker to tow you into town, it is all right to pass such a call by amateur radio. However, if you made a call just to find a particular color of seat covers, the call would not be permitted. The crucial key as to whether a third party call or message is permitted depends on how desperate the situation is concerning the welfare of one or more persons. Apparently, the discussion of price of the article or service should be avoided. The writer realizes that this is most difficult to decide, what is welfare and what is not (reminds one of the definition of "sin"), but these are the only guidelines we have been able to get from the FCC. Thanks to W5EKP.

The folks who really got CB going – the truck drivers – may well get a new phase of the personal communications boom going. That's the illegal use of amateur VHF gear to escape the QRM on 27 MHz. A number of

clubs have reported that truckers are buying 2m rigs and gathering on 146.58 MHz, CB handles and all! WBØECX, via *Grid Leak*, reports he's on the lookout for bogus calls in the Denver area, after a check by area amateurs came up with 75 suspected phony calls in less than a day of casual monitoring. Thanks to *Grid Leak*, bulletin of the Pueblo Ham Club, Pueblo CO.

From club bulletins comes the news that 10m intruders are a growing problem. Several clubs report discussions on the topic, but most stopped short of any concrete action, choosing instead to "express our concerns to the ARRL." FCC officials are anxious for reports on the intruder problem both on HF and VHF, with your district engineer topping the list of where to send the information.

Illinois is the latest state to add anti-scanner laws. But amateurs are exempt in the final version of the legislation, largely through the work of statewide amateur clubs and organizations. The law bans the use of VHF and UHF monitors and transmitters in cars, unless the operator holds an FCC license (amateur or commercial). Most states with scanner laws on the books do exempt amateurs, but the best advice is to carry a photocopy of both the law and your license, to prove your point to law enforcement authorities. The Illinois law was expected to take effect October 1st, but will have to be added to the scores of other laws needing revision should the CB band be moved into the VHF/UHF region.

Tests are supposed to begin next fall on the new early warning over-the-horizon radar under construction in Maine by GE. The 39 million dollar system features 100 mile spacing between transmitter and receiver, a "footprint" of 1 million square miles in area, a transmitting antenna measuring 2,276 feet wide and 135 feet high, and 21 transmitters, rated at 100 kW each. Seven of them are to be used at a time over frequencies ranging from 5 to 30 MHz. *Electronics* magazine also reports that the beam can be scanned in azimuth and range simply by shifting frequency. The receive end has a 5,816 foot antenna, and will relay 96 three stage superheterodyne receivers to processors, and then into the Air Force radar system. Big Noise, anyone?

Another 10m beacon has been established here in the US. It's N4RD at Englewood FL on 28.075 MHz, full time. Power is 45 Watts output to a ground plane antenna. Owner/operator Robert Davis K4BRD says he's received over 100 QSLs since putting the beacon on the air at noon April 3rd. "This project was first conceived about a year ago," Davis told *73*. "I was listening on the 10m band and it was completely dead. I tuned down to the CB band, and it was very active. I realize that there is a difference in propagation between 11m and 10m, but it did not seem possible that there was that much difference. I came to the conclusion that no one was transmitting on ten. But how many were listening? What would be the result if there were a beacon on 10m? If the beacon was heard by someone, perhaps if they called CQ they could make a contact." Davis then found out that the IARU supervises beacons internationally, and he was assigned his frequency after contacting the coordinator in London, England. N4RD is home brew, with a Morse identifier. Other US 10m beacons include WA1IOB in Massachusetts on 29.150 MHz. For other beacon stations see May *73*, page 13.

New Hampshire and Massachusetts are not exactly the best of neighbors. NH Governor Meldrim Thomson regularly criticizes the "mess" south of his state's border, while Massachusetts officials are quick to point out the lack of services available to New Hampshire residents compared to those offered in their state. A real war is underway between the two states over lotteries, liquor stores, horse and dog racing, and a half dozen other perennial issues, all debated over the Boston TV stations both states share. New Hampshire, says Governor Thomson, will not take a back seat to anyone . . . and he especially means Massachusetts. With that background in mind, it won't be hard to understand the logic of a bill introduced in the current session of the New Hampshire legislature, to specifically allow the use of microphones while mobile. Massachusetts ("Briefs," April *73*) has a little known law banning operation of motor vehicles without both hands on the wheel. At deadline the NH bill was before the house transportation committee. Anyone for a radiotelegraph endorsement? Thanks to WA1YEG.

With thanks to the never tiring editor of the *West Coast DX Bulletin*, here are a few tidbits from the DX world. The logs, equipment, and QSLs of D2ASW were confiscated by the Angolan authorities, and the operator headed for Portugal in quite a hurry . . . all this in light of recent problems in Angola. In Dahomey, 9G1JN ran into problems trying to get a TY license . . . seems a coup attempt may be responsible. W6YO appeared for 24 hours from Pitcairn on a CW only visit. Many CW DX types reportedly were grumbling about too much rag chewing and not enough QSOing. CEØAE, faced with rig problems, got a new Atlas onto Easter Island via W6YO, who's returning the original for factory repair. It seems Atlas played a big role in forwarding the replacement pending arrival of the ailing unit. A late March fire destroyed the Central Bureau of VERON at Arnhem in the Netherlands. Some records and subscription lists were lost, so those receiving *DX-Press* or awaiting correspondence are asked to write VERON, Box 1166, Arnhem, The Netherlands.

At deadline: The FCC approved a 30 day extension for comments on dockets 21116 (the proposed ban on linears capable of 24-32 MHz) and 21117 (type acceptance of ham gear). It was also reported that the manufacturer's association bid to enact a grandfather clause covering docket 20777 (bandwidth) was near approval.

Little reaction has been forthcoming on the disturbing suggestion in the book *The Real Spy World* by Miles Copeland, a former CIA organizer, that amateur transmissions are sometimes used for clandestine intelligence operations. He suggests that high speed "squirt" or "screech" signals are sometimes played in the background of ordinary ham radio messages. Copeland claims that squirt recordings "are still used to good effect on ham radio transmissions." It is hoped that if the CIA or any other organizations have ever used amateur radio in this way, the practice has long ceased. Reprinted from *The Indian Radio Amateur*, New Delhi.
